St. Louis Expanded Metal Fireproofing Co., of St. Louis, Mo. As shown in Fig. 25, the reservoir comprises two compartments of equal size, divided by a partition wall. Each compartment is 50 x 60 ft., inside dimensions, with rounded corners. The roof is a flat slab, 3 ins. thick, resting upon girders, these girders being supported by columns of a square cross-section.

Reinforcement.—The reinforcement is rather heavy, especially for the walls. As the latter are thin, the metal reinforcement occupies a relatively large portion of the wall space. The reinforcement consists of corrugated bars for the footings, floor, walls, columns, beams and roof girders, and expanded metal for the roof slab. The bars were of four different sizes; $\frac{1}{2}$ -in., $\frac{3}{4}$ -in., $\frac{1}{2}$ -in. and 1-in., and of different lengths, varying according to the location where used. In

the floor the reinforcement consisted of $\frac{3}{4}$ -in. bars laid crosswise in two layers and spaced 12 ins. apart in each layer. In the walls the reinforcement was placed close to both inner and outer faces. Near the inner face a row of upright, $\frac{3}{4}$ -in. bars, spaced 12 ins. between centers, extended the entire length of enclosing and partition walls. Horizontal $\frac{3}{4}$ -in. bars, 24 ins. between centers, were placed against these uprights. Near the outer wall face $\frac{3}{4}$ -in. upright bars were used, spaced 9 ins. between centers; and the horizontal reinforcement was of $\frac{3}{4}$ -in. bars, 24 ins. between centers. In the footings two layers of $\frac{3}{4}$ -in. bars were used. These were laid crosswise and spaced 6 ins. apart in each layer.

Concrete.—The specifications required broken stone of hard consistency, not larger than a $\frac{3}{4}$ -in. cube, and clean, sharp sand, the composition of the concrete to be one cement to two sand and four stone. These proportions were used throughout the work. Colorado Portland cement was used for the greater part of the work. Towards the finish a carload of Iola, Kansas, Portland cement was used. Both cements showed up well under frequent tests and gave excellent results in the work. The sand was obtained from a pit about three miles distant; it was of medium quality and fairly clean. The stone used was obtained partly from a limestone quarry situated at some distance from the reservoir site; but the greater portion of the supply was obtained from boulders found on the surface in the vicinity.

Excavation.—The reservoir was built so that about half of its height was below the natural level of the ground. The excavation was made in coarse gravel mixed with some sand and clay, the material being handled with teams and scrapers. The force employed in excavating consisted usually of four or six teams and about the same number of men in addition to the drivers. The men were paid \$2.50 per 10-hour day and the wage for team and driver was \$5 per day. A portion of the material was removed by drag scrapers, but the bulk of the excavation, consisting of compact gravel mixed with small boulders, required the use of wagons. The material was loosened by plow for scraper work for the upper portion of the excavation. It was found later, however, that better headway could be made by loosening the material with picks and shoveling it into wagon by hand. The total volume of material excavated was 2,275 cu. yds. at a cost of \$1,114.75, or 49 cts. per cu. yd., divided as follows:

	Per cu. yd.
Loosening and loading	20 cts.
Hauling and depositing.....	25 cts.
Supervision, tools, etc.....	4 cts.
Total	49 cts.

After the excavation was completed the bottom of the pit was compacted with a heavy roller, then the excavations for wall and column footings were carefully made by hand.

Concrete Work.—The concrete was mixed by hand on a movable platform; its composition is given above.

A concrete gang consisted of four men who were each paid \$3.75 per day. They wheeled the materials from the supply piles to the mixing platform, mixed the concrete and deposited it in place. During the construction of the footings and floor two concrete gangs were employed, but after the walls were started one gang only was required for concrete work; the other gang was then put to work assisting the carpenters.

The sand and stone were wheeled to the platform in iron wheelbarrows of $2\frac{1}{2}$ cu. ft. capacity. The cement was in $\frac{1}{4}$ -bbl. sacks and each sack was taken as 1 cu. ft. Each batch of concrete contained the following quantity of material:

2 $\frac{1}{4}$ sacks of cement.....	2 $\frac{1}{4}$ cu. ft.
2 wheelbarrows of sand.....	5 cu. ft.
4 wheelbarrows of stone.....	10 cu. ft.

The quantities of sand and stone were adjusted so as to form the proper proportion for making a dense concrete. From time to time as the work progressed, experiments were made by the writer to determine the percentage of voids both in the sand and the crushed stone; and, in this way, uniformity in composition was secured for the concrete. The mixture was made quite wet in order to insure a free flow around the reinforcing bars. On account of the narrow space inside the forms and the number of reinforcing bars therein care was taken to cause the mixture to be well distributed throughout. The wet concrete was well spaded in an effort to secure a smooth surface next to the forms. This was generally accomplished, but some rough places which showed after the removal of the forms required patching up.

In constructing the footings some concrete was first deposited in place and the metal reinforcement was embedded therein. For the floor reinforcement the lower bars were carefully embedded in the concrete after it had been brought to a suitable height; the upper bars were then placed crosswise upon the lower ones and kept in position until the remainder of the concrete had been deposited around and over them. In the wall footings a depression or groove, several inches deep, was left under the wall space for its entire length. This insured a good bond between the wall proper and the footing.

The concrete floor in each compartment was built in one continuous operation, the object being to secure a practically monolithic construction. The lower reinforcing bars in the floor were embedded at the proper depth in the fresh concrete and the upper bars were then placed crosswise upon the lower ones; the two sets were then wired together at a sufficient number of places to prevent displacement while the remaining concrete was being deposited around and over them.

Placing Reinforcement—The reinforcement for the walls and columns was erected in place upon the footings and formed a steel skeleton around which the forms were erected. The upright bars in the walls were held together and at the proper distance apart by means of templates consisting of wooden strips in which holes were bored at suitable intervals to receive the bars. These templates

were maintained in a horizontal position and were moved upward as the concrete advanced in height. The horizontal reinforcing bars were wired in place to the upright bars; they were placed in position ahead of the concreting as the wall was built up.

The corrugated bars in beam and girders were placed in position in the forms and held up by blocks which were removed as the forms were filled with concrete. The expanded metal reinforcement for the roof slab was placed so as to be close to the lower face of the slab, but far enough up to be entirely enveloped in the concrete.

Form Construction.—The wall forms were made of 2-in. planks, surfaced on the inner side and placed horizontally on edge. They were held in place by 4 x 4-in. posts spaced at intervals of about 4 ft., in pairs on opposite sides of the wall. The posts were firmly braced on the outside; they were prevented from spreading by connecting wires passing through the wall space between the edges of adjacent planks. At the rounded corners of the reservoir the pairs of posts were spaced about two feet apart and the curve was made by springing thin boards into place to fit the curve and nailing them to the posts. The posts were high enough to reach to the top of the wall; the siding was built up one plank at a time as the concrete work progressed. Column forms were made of 2-in. planks on end, extending from floor to girder. Three sides were enclosed and one side was left open to receive the concrete; this side was closed up as the concreting advanced in height.

The beam and girder forms were open troughs of the required dimensions, made of 2-in. plank, surfaced on inner faces. The form of centering for the roof slab consisted of a smooth, tight floor of 2-in. planks, extending between the open tops of column, beam and girder forms over the entire area between enclosing walls of the reservoir. The centering and the beam and girder forms were supported by 6 x 6-in. posts resting upon the floor below.

The regular carpenter gang consisted of a foreman carpenter at \$5 per day, a carpenter at \$3.50 per day, and two helpers at \$2.75 per day. During the early concrete work of making footings and floor, where forms were not required, the carpenter force was employed in erecting the steel skeleton for the walls. The upright bars were placed in position and secured by temporary wooden stays extending from the upper portion of bars to the surface of ground outside of excavation. These stays were removed after concreting had advanced to a sufficient height to hold the steel securely in place.

Cost of Concrete Work.—The wages paid the concrete gang which mixed and placed all the concrete and the carpenter gang which constructed and erected the forms and placed the reinforcement have been given above. The costs of construction materials on the site were:

Cement, per barrel.....	\$ 2.57
Sand, per cu. yd.....	1.80
Stone, per cu. yd.....	3.15
Lumber, per M ft. B. M.....	27 50

The quantities in the completed concrete structure were as follows:

	Cu. yds.
Total volume of concrete in reservoir.....	704.71
Total volume of steel reinforcement in reservoir.	5.57
Total volume of material in completed structure.	710.28
Volume of material in structure exclusive of roof slab	648.35
Volume of material in roof slab.....	61.93
Total	710.28

The cost of the structure per cubic yard of concrete, exclusive of the roof slab, was as follows:

Item.	Per cu. yd.
Crushed stone	\$ 3.168
Sand842
Cement	3.859
Reinforcement	4.959
Labor, mixing and placing concrete.....	1.721
Forma, labor and material.....	2.960
Total ..	\$17.509

In constructing the roof slab the expanded metal reinforcement raised the unit cost. For this portion of the work the costs were:

Item.	Per cu. yd.
Expanded metal reinforcement.....	\$ 5.241
Other items, same as above.....	12.550
Total	\$17.791

Plastering and Waterproofing.—According to the requirements of the specifications the floor and the inside surface of reservoir walls were covered with a coating of cement mortar composed of one part Portland cement and one part sand. The wall plastering was from $\frac{1}{4}$ in. to $\frac{3}{4}$ -in. thick; it was applied in two coats. The floor finish was laid in alternate strips about 1 in. thick and 3 ft. wide. After the strips first laid had hardened the remaining strips were laid, the edges being grouted to insure tight joints.

The outside of walls and roof was covered with a coating of tar which was heated in an open kettle to a temperature of about 360° F. and then applied with a brush or mop.

The cost of wall and floor plastering was 44.4 cts. per square yard, itemized as follows:

Cement	26.4 cts.
Sand	2.6 cts.
Labor	15.4 cts.
Total	44.4 cts.

The cost of outside waterproofing was 4 cts. per square yard, distributed as follows:

Material	2.5 cts.
Labor	1.5 cts.
Total	4.0 cts.

Backfilling.—The entire structure, after completion, was covered with earth to a depth of 2 ft. above the roof, sloping on all sides to the natural surface of the ground. The earth composing this fill was handled by means of teams and scrapers; this method

caused the material to be compacted firmly in place and at the same time afforded a good test of the rigidity and strength of the roof.

The backfill gang consisted of four teams and from four to six laborers in addition to the drivers. Drag scrapers were used to move the material from the spoil banks and place it over and around the reservoir. Part of the material was side dumped from runways and shoveled to place between the walls of reservoir and sides of excavation. This material was carefully tamped and compacted as the filling progressed. The wage of team and driver was \$5 per day, and for laborers for this work, \$2.50 per day of ten hours.

The amount of backfilling was 2,039 cu. yds. and its cost was 30 cts. per cubic yard, distributed as follows:

Loosening and loading materials.....	12 cts.
Hauling and depositing.....	17 cts.
Supervision, tools, etc.....	1 ct.
Total	30 cts.

Summary of Costs.—The total cost of the completed reservoir, exclusive of pipe connections with water mains, was \$15,068.76. The cost of the various items was distributed as follows:

Main structure, 648.35 cu. yds., at \$17.509..	\$11,351.96
Roof slab, 61.92 cu. yds., at \$17.91.....	1,101.79
Ventilators, doors, stepping irons, etc.....	164.08
Plastering, 1,517 sq. yds., at 44.4 cts.....	673.08
Waterproofing, 1,285 sq. yds., at 4 cts.....	51.40
Excavation, 2,275 cu. yds., at 49 cts.....	1,114.75
Back fill, 2,039 cu. yds., at 30 cts.....	611.70
Total	\$15,068.76

While some of the cost items are apparently high when compared with the cost of similar work in other places, it should be remembered that the isolated locality and the local conditions were unfavorable for low cost. Owing to the isolated location of the reservoir with respect to large markets and also to local sources of supply the cost of material and labor was quite high. All construction material, except some of the stone for crushing, had to be hauled over a mountain road from 3 to 4 miles to the top of the hill selected for the reservoir site. Labor was scarce and commanded a wage of \$2.50 per day for ordinary work; the laborers mixing concrete were paid \$2.75 per day. Another source of considerable expense was the high cost of lumber and carpenter work on the forms. On account of the thinness of the walls and roof, the cost of lumber and labor required per cubic yard of concrete was considerable. A part of the lumber was used the second time in forms, but it was found impracticable to delay the work by waiting for the concrete to harden before beginning the new portions of the walls. This lumber was sold after the completion of the work, but the salvage was inconsiderable, amounting to less than 10 per cent of the original cost.

The writer kept a record of cost of the various items of material and labor entering into the construction of this reservoir. This

record was verified by comparison with the vouchers and pay rolls of the contractor and was made as complete and accurate as possible. From these data the above statements of construction cost have been compiled.

Cost of Concrete Reservoir, Pomona, Cal.*—Mr. Charles Kirby Fox gives the following:

The concrete reservoir herein described was erected in the summer of 1904 on Point Lookout, Ganesha Park, Pomona, Cal. It was designed by Mr. Geo. P. Robinson, City Engineer, and Mr. Albert Simmons had the contract. The writer was in direct charge of construction.

The reservoir is oval in form (Fig. 26), being 77.7 ft. by 40.7 ft. over all. It is 12 ft. deep and the floor has a slight slope to the

Fig. 26.—Concrete Reservoir.

sluice box. Iron ladders are placed in each of the quarter points. The inlet and overflow pipes are near the top of the walls, the discharge pipe is 12 ins. above the bottom of the reservoir and the sluice pipe is set in a bowl 3 ft. in diameter and 4 ins. deep. It is the lowest part of the reservoir.

The walls (Fig. 27) are 12 ft. high. They were designed to be 6 ins. thick at the top and 15 ins. thick at the bottom and to be connected with the bottom of the reservoir with a 12-in. radius. The bottom is 4 ins. thick. Before the walls were started it was decided to add a 6 x 30-in. ring to the outside of the top, making the

**Engineering-Contracting*, April 15, 1908.

top 12 ins. wide. The joint connecting the walls with the bottom was put in about 12 ins. from the inside edge of the radius.

Around the sluices and inlet and outlet pipes a larger mass of concrete was used. The finish was $\frac{1}{2}$ -in. thick and was water-proofed.

The contract price of the reservoir was.....	\$1,625.00
Extra concrete in ring, 8.3 cu. yds....	60.90
Extra valve, screws, etc.....	16 00
	<hr/>
	\$1,701.90
Include valve box changed.....	\$ 25.00
Cost of reservoir.....	1,726 90

Excavation.—The greater part of the excavation of the oval, about 77 x 40 ft., and the tunnel was done by the city by force account. 1

walls and bottom
Eng. Contr

Fig. 27.—Concrete Reservoir Wall.

have no records of the costs of this part of the work. The contractor trimmed down the sides and bottom of the reservoir, in all about 5,000 sq. ft., at a cost of \$71.60, or $1\frac{1}{2}$ cts. per sq. ft.

Pipes, Valves, Etc.—The pipes, valves, etc., as provided in the specifications cost \$455.52 and the extra valve sets installed cost \$16. The laying of the pipe cost \$9.70. The tunnel excavation to get down to grade cost \$52.38, making a total of \$533.60. This includes 5 8-in. Ludlow valves, 270 lin. ft. of heavy 8-in. cast-iron pipe and 80 ft. of 6-in. vitrified pipe, all installed.

Cleaning Up—The contractor mixed the concrete for the walls on the floor of the reservoir and to clean out his old concrete cost him \$22.25. The final clean up cost him \$7.00, making a total cost for cleaning up of \$29.25

Concrete.—The concrete was specified to be 1 part cement, 2 parts sand and 4 parts gravel (pea size to 2-in. ring). As put in, a cement-barrel was filled and emptied six times with the bin run of sand and gravel and four sacks of cement (1 bbl.) were emptied on top of it; it was then turned wet. The costs per cu. yd. were:

	Per cu. yd.
Labor	\$1.09
Cement, 1.08 bbl., at \$3, delivered.....	3.23
Sand and gravel, at \$1.....	0.93
Water (had to be pumped).....	0.34
Forms, labor and lumber.....	0.76
Total	\$6.35

The wages paid labor were \$1.75 and \$2 per day, foreman mason \$4 per day. Carpenters were paid 43 cts. per hour and lumber cost \$33 per M ft. B. M. A 9-hour day was worked.

Finish—The $\frac{1}{2}$ -in. finish was specified to be 1:1, but that did not work well, so we increased the amount of sand. It was water-proofed. It was mixed very thoroughly with 35 lbs. alum at 6 cts. per lb., and then the water, containing 35 lbs. good potash soap per cubic yard of mortar was added. The finish cost:

	Per cu. yd.
Materials	\$14.45
Labor, mixing and applying.....	11.90
Total	\$26.35

On the finishing there were two masons at \$4 plastering and enough laborers to keep them supplied with mortar. The completed floor cost 9 cts per sq. ft.

Summary of costs:

Cement, at \$3 per bbl.	\$ 481.50
Sand, at \$1 per cu. yd.....	113.30
Soap and alum, at 6 cts. per lb.....	21.00
Water	43.00
Timber	30.00
Labor and superintendence.....	361.35
Pipe laying (contract price).....	533.60
Total	\$1,583.75

The reservoir has now been in use $3\frac{1}{4}$ years and has given excellent satisfaction. Only a few hair cracks have appeared on the surface and none of the plaster has scaled off.

Cost of Storage Reservoir, Hagerstown, Md.*—In 1902-3 the water supply of Hagerstown, Md., was improved by the construction of a storage reservoir to impound the waters of the two streams known as Warner's Hollow Creek and Raven Rock Creek. The works were designed and constructed by the American Pipe Manufacturing Co., of Philadelphia, Pa., Mr. J. W. Ledoux, M. Am. Soc. C. E., Chief Engineer.

Earth Dam and Accessories.—The general construction of the earth dam is shown by the section of Fig. 28. Owing to scarcity of

**Engineering-Contracting*, Oct. 10, 1906

Fig. 28.—Sections of Earth Dam.

available material only the upstream half of the dam and the puddle walls were made of selected material; the downstream half of the dam was made of earth and loose rock. The main puddle wall varied from 5 to 10 ft. in width and from 6 to 20 ft. in depth, and contained 1,602 cu. yds. of material, the secondary puddle wall was narrower and shallower, containing only 712 cu. yds. of material. Both slopes of the dam are riprapped and it is pierced by a 30-in. cast-iron pipe blow-off and two 12-in. cast-iron supply mains. There was also some 1,286 cu. yds. of $3\frac{1}{2}$ -ft. thick dry rubble retaining wall built in connection with the dam work. The costs of these several items of the dam work are given from figures furnished by Mr. Lédoux, as follows:

Dam.—There were 93,200 cu. yds. of embankment built at a total cost of \$60,532, or \$0.65 per cu. yd. The several items of cost were as follows.

Items.	Per cu. yd.
Foreman	\$0.0243
Hauling	0.2691
Labor	0.2252
Sprinkling	0.0144
Picking stones	0.0192
Trimming slopes	0.0080
Tools, blacksmithing, powder, etc.....	0.0479
Superintendence and engineering....	0.0751
Protecting for winter.....	0.0056
Total ..	\$0.6491

Rip-rap.—The embankment slopes were rip-rapped with stones of $\frac{1}{2}$ cu. ft. or less, placed by hand to fairly uniform thickness, after which broken stone of 3 or 4-in. sizes were spread on top and trimmed to an even slope. Altogether 3,844 cu. yds. of rip-rap stone and 1,882 cu. yds. of broken stone were placed at a cost of \$5,059.69, or \$0.884 per cu. yd.

Puddle Walls.—The two puddle walls aggregated 2,314 cu. yds. of puddle, the main wall having 1,602 cu. yds. and the secondary wall 712 cu. yds. The puddle was deposited loose and then flooded with water and tramped by men with rubber boots. When the top of the puddle reached a level about 3 ft. from the natural surface of the ground the amount of water was diminished to just enough to permit the clay to be tamped with rammers weighing about 20 lbs. The cost of the puddle walls was as follows:

No. 1.	Per cu. yd.
1,602 cu. yds. excavation.....	\$1.02
Placing puddle	0.60
Tools, etc.	0.48
Total	\$2.10
 No. 2.	
712 cu. yds. excavation..	\$0.98
Placing puddle ..	0.80
Crushed stone in puddle....	0.26
Pumping, tools, etc	0.40
Total	\$2.44

Masonry Walls.—The cost of these was:

	Total.	Per cu. yd.
Masonry cut-off walls, 52 cu. yds.	\$ 262.34	\$5.04
Dry retaining wall, 1,286 cu. yds.	\$1,601.53	\$1.246

Gate House.—The gate house cost \$951.76, made up of the following items:

Concrete, 2½ cu. yds.	\$ 13.20	\$5.28
Rubble masonry, 15 cu. yds.	93.41	6.23
Broken range masonry, 24 cu. yds.	534.07	23.07
Red tile roof, complete.	311.08
Total	\$951.76

Blow-Off Pipe.—The 30-in. cast-iron blow-off pipe through the dam cost \$1,761.75, or \$5.96 per lin. ft., made up of the following items:

Items.	Per lin. ft.
Pipe	\$4.00
Excavation	0.36
Filling	0.23
Freight, hauling and laying ..	1.17
Total	\$5.76

Spillway.—The spillway contained 1,224 cu. yds. of 1:3:5 concrete masonry. Its total cost was \$9,820.43, made up of the following items:

Concrete	\$6,457.72
Top lining of 1-in. yellow pine.	918.05
Excavation	1,830.90
Rip-rap on slopes above walls.	78.44
Timber, crib at foot.	535.32
Total	\$9,820.43

The concrete work, 1,224 cu. yds., cost \$5.25 per cu. yd., made up as follows:

Item.	Per cu. yd.
Cement, 4.82 bags.	\$1.795
Sand	0.860
Stone	1.081
Labor	0.971
Tools, forms, etc.	0.541
Total	\$5.248

Raven Rock Creek Intake.—To bring the water from Raven Rock Creek to the main storage reservoir a masonry intake dam was constructed on that stream, and from this dam a 30-in. terra cotta pipe line was constructed to the storage reservoir. The cost of the intake dam was \$3,223.89. The itemized cost of the masonry work was:

Item.	Per cu. yd.
Excavation, 145 cu. yds.	\$ 0.92
Rubble masonry, 158 cu. yds. ..	12.45
Concrete coping, 14 cu. yds.	13.21

The 30-in. pipe line is composed of extra heavy terra cotta pipe, with deep bells corrugated on the inside, furnished by A. N. Pierson,

New York, N. Y. It was 2,244 ft. long and cost, complete, \$3,932.03. The itemized cost per foot was as follows:

Items.	Per lin. ft.
Pipe	\$2.486
Cement for joints.....	0.057
Jute for joints.....	0.068
Trench, tools, etc.....	1.370
Total	\$3.981

Grubbing and Clearing.—The reservoir area of 15.1 acres had all trees and brush cleared off and all stumps grubbed up. The trees were generally removed by blasting. A force of about 20 men was worked, their wages being \$1.50 per day. No record was kept of the area cleared per day, but the cost of clearing and grubbing is given as \$107.13 per acre. The costs of two floodwood racks were \$30.74 and \$21.60; both were constructed as follows: Two heavy logs were laid horizontally across stream, one about 3 ft. above the bottom of the stream and the other about 8 ft. above the bottom and parallel to the first, but upstream, so as to make a slope of about 1 on 1. To these two logs were spiked 6-in. timbers reaching down to the bed of the stream. The transverse logs were supported against the roots of trees and all the timber was rough stuff, such as could be obtained on the site—chestnut, oak or spruce. While the work was in progress water was supplied by means of 1,776 ft. of rectangular trough, composed of three 12-in. posts nailed together and laid at a grade of 1 per cent. Considerable trestling was necessary. This trough cost \$303.93, or 17.1 cts. per lin. ft.

Cost of a Wooden Covering for Reservoir, Quincy, Ill.—Mr. Don R. Gwinn gives the following:

The reservoir was 415 x 317 ft. at top, 26 ft. deep, inside slopes $1\frac{1}{2}$ to 1. A vegetable growth had given much trouble, so the reservoir was roofed over in 1898 at a cost of 4 cts. per sq. ft., the price of lumber being at that time only \$15 per M. There were 260,000 ft. B. M. used (or 2 ft. B. M. per sq. ft.), and 38 kegs of nails at \$1.85 per keg. The pedestal piers or foundations for the posts were of brick (\$7 per M), 21 ins. sq. at the base, 16 ins. at the top, 18 ins. high and capped with a limestone slab 12 x 12 x 6 ins. (43 cts. per cap). A $\frac{3}{4}$ x 3 in. dowel pin was let into each cap $1\frac{1}{2}$ ins. The posts were 6 x 6-in. x 22 ft., spaced 14 ft. in one direction and 18 ft. in the other. They were capped with 6 x 6-in. caps, or girders, 18 ft. long. On these caps were laid 2 x 6-in. joists or stringers 14 ft. long spaced 4 ft. c. to c.; and on the stringers were laid 1-in. roofing boards (1 x 10 in. x 16 ft.). These boards were laid north and south to exclude sunlight from the cracks as much as possible.

Two posts and a cap were framed and fastened together on the ground, and sway braced with two braces of 2 x 6, and then up-ended. Joists were then shoved out from the completed part of the roof, and laid flat upon the caps; two joists being thus laid upon, and nailed to, each end of the cap, to serve as walking planks for the workmen. The joists were then spaced properly by means of

gates, and then braced with 2 x 4-in. "bridging." White pine was used throughout, all the dimension stuff being No. 1, and the roofing boards No. 2. Of the total surface of the roof, 25% is trap doors.

In the section on Timberwork will be found further data on the cost of wooden coverings for reservoir. See the index under "Timberwork, reservoir roof."

Cost of a Reservoir Embankment.—The Tabeaud Dam in California is an earth embankment 100 ft. high, containing 370,000 cu. yds. of embankment. Mr. Burr Bassell is authority for the following:

The dam was built by contract in 1901, the contract price being 40 cts. per cu. yd. During the months of August, September and October more than 2,000 cu. yds. were built per working day (53,000 cu. yds. per month). Mr. Bassell states that the maximum force was 223 men and 416 horses and mules. Fresno scrapers were used to load wagons through "traps." There were 4 horses on each fresno and 4 horses on each wagon. Assuming \$1.50 per day for laborers and \$1.00 per day for horses, we have a daily cost of \$716, or nearly 36 cts. per cu. yd., the output being 2,000 cu. yds. per day. The wagons, tools, etc. (exclusive of horses) were worth about \$16,000. Allowing 3% per month for interest, depreciation and repairs, the daily plant charge would be about \$20, or 1 ct. per cu. yd. Allowing 5% for general supervision and overhead charges, we have nearly 2 cts. more per cu. yd., or a total cost of 39 cts. per cu. yd.

The average haul was $\frac{1}{4}$ mile.

The earth (a clay mixed with gravel) was spread in 6-in. layers, sprinkled and rolled. To spread the 2,000 cu. yds. of embankment daily, there were 3 road graders operated by 6 horses and 2 men on each grader. There were 2 rollers, each operated by 6 horses and one driver. There were 2 harrows, and, while Mr. Bassell does not so state, presumably 4 horses and a driver to each harrow. At \$1.50 per 10 hr. day for each man and \$1 for each horse, we have following cost:

	Per cu. yd.
	Cts.
Spreading	1.5
Sprinkling	0.8
Harrowing	0.6
Rolling	0.8
Total	3.7
Loading and hauling	32.3
General expense (estimated)	2.0
Plant charge (estimated)	1.0
Total	39.0

Test pits dug in this dam showed a weight of 133 lbs. per cu. ft. of compacted earth.

The above given yardage relates to the yardage in the embankment, not in the barrow pits.

The rates of wages are merely assumed for illustration. It is probable that laborers received \$2 per day at that time and place.

Cost of a Concrete Core Wall.*—This article covers the construction of 2,184 ft. of core wall, being a portion of a wall which will ultimately be $2\frac{1}{2}$ miles long. This wall was built along the toe on the pool slopes of a rock-fill dam in a trench excavated to solid rock. The face of the wall has a batter of $3\frac{1}{2}$ in 12 and the back conforms to the face of the side of the trench below water and is practically vertical above water, being 2 ft. wide on top. Level with the top a 6-in. concrete apron extends back 20 ft. over the top of the rock-fill dam. The wall varies in height from 10 to 21 ft. It was built of 1 : 5 gravel concrete and is reinforced as follows: A longitudinal line of old steel bars was placed in the center of the wall 6 ins. below the top. Over this horizontal bar were hooked vertical bars spaced 6 ft. apart. This reinforcement was used principally to anchor down any pieces of the wall top which might break away.

Forms.—As fast as the dipper dredge opened the footing trench to rock, 2-in. holes 10 ft. apart were drilled into the ledge. Uprights of 6 x 8 in. timbers having 2-in. rods 6 ft. long bolted to the bottoms were erected by inserting the rods in the drilled holes and bracing the tops back to posts set into the rock-fill dam. The uprights were set to the inclination of the face of the wall. Waling pieces, 6 x 6 ins. x 16 ft. were connected several end to end by bevel joints, with one bolt in each so the joint would be flexible. The several lengths of waling pieces were thus connected inside the uprights. A vertical plank was then bolted to the waling near a joint, and by it the joint was pushed down under water 3 ft., and a second waling was bolted to the plank at the surface of the water. Other planks were then bolted to the first waling at the joints on each side of the joint first sunk, and these joints were in turn pushed down 3 ft., permitting the second waling to be bolted to the planks. In this manner one waling after another was added at 3-ft. intervals until the first waling had been pushed down to rock. The walings were not fastened to the uprights, as the up-thrust of the water pushing them against the slant of the uprights held them fast.

The lagging consisted of vertical 2 x 12-in. planks, set close inside the walings; these planks were nailed to the topmost waling, but were not fastened to the lower walings.

The forms were built around curves without alterations, as the one-bolt waling joints gave considerable flexibility. Ordinarily, the wall was concreted in alternate 30 to 50-ft. sections. The forms were built continuously in advance, and torn down behind as fast as the concrete set. At the ends of sections of wall, transverse bulkheads were built inside the form and bonding recess forms fastened to them. To remove the forms the braces from the tops of the uprights were unbolted and the whole form was pushed away from the wall and taken apart. As the forms were not nailed, except at one point, as noted above, the lumber was but little damaged, and, with the addition of a small amount of lagging,

**Engineering-Contracting*, Mar. 10, 1909.

there is enough lumber remaining from the form-work for the first 2,184 ft. of wall to build the remainder of the wall. The form lumber was used from three to four times on the portion of the wall that is now completed.

Concreting.—The concrete mixing and handling plant was mounted on an 18½ x 100 ft. barge. On one end of the barge was a ¼ cu. yd. Chicago concrete mixer with a gravel supply bin mounted overhead. On the opposite end of the barge a stiff-leg derrick, operated by a bull wheel, was erected. This derrick handled the gravel from stock barges moored alongside to the supply bin over the mixer, and also handled the concrete, from the mixer into the forms. A wooden bottom dump bucket was used to deposit the concrete under water and did the work successfully up to a depth of 17 ft.

Wages and Cost.—The gang for forms consisted of 2 carpenters and from 2 to 6 helpers and a drill boat crew setting uprights; and the gang for concreting of 14 men, including foreman, derrickman, mixerman, etc. The wages paid were as follows:

Drillmen, per month	\$ 50
Foreman, per month	75
Overseer, per month	125
Carpenters, per day	2.50
Laborers, per day	\$1 to \$1.25

All men were subsisted in addition to regular wages, which was considered equivalent to 50 cts. per day per man additional. The prices of materials were as follows:

Coal, per ton	\$ 2.20
Corrugated bars	2.85
Round bars	1.80
Cement, per bbl., f. o. b. Moline	1.14
Gravel, per cu. yd. on barge, towing extra	0.65
Lumber, per M. ft., B. M.	26.50

The cost of the work was as follows:

Item.	Total.	Per cu. yd.
Preliminary expense	\$ 9,074.30	\$2.0441
Supt. and office	1,798.30	0.4051
Excavation	467.50	0.1053
Totals	\$11,340.10	\$2.5545

Concrete work:

Forms—		
Materials	\$ 2,575.30	\$0.0351
Labor	940.06	0.2117
Drilling	168.10	0.0379
Coal for drills	94.57	0.0213

Totals \$ 3,778.03 **\$0.8060**

Concrete materials—

Cement	\$ 7,059.48	\$1.5901
Cement handling	169.11	0.0381
Cement testing	130.68	0.0294
Gravel	2,847.85	0.6415
Reinforcement	104.08	0.0235
Towing	945.78	0.2131
Towing, coal for	378.28	0.0852

Totals \$11,635.26 **\$2.5210**

Mixing and placing concrete:		
Labor	\$ 2,054.80	\$0.4628
Coal	283.71	0.0639
Totals	\$ 2,338.51	\$0.5267
Back filling	\$ 203.64	\$0.0459
Subsistence	1,327.32	0.2991
Plant repairs	298.66	0.0673
Totals	\$ 1,829.62	\$0.4123
Grand total (4,339.1 cu. yds.)	\$30,721.32	\$6.9205

Regarding these items it needs to be noted that the \$9,074.80 for preliminary expenses includes a large number of miscellaneous items, including new machinery, erection of plant, etc., charged out in full. To compare the work with a contract job the engineer suggests taking this item at about \$5,000, which represents about a 20 per cent depreciation charge on all plant used. It should be noted also that all form lumber is charged in full against this 2,178 ft. of wall, yet, as stated above, it is enough to build the remainder of the wall and should ultimately be charged against the total yardage. In the same way most of the items constituting preliminary charges must be distributed over a large yardage in addition to that of the wall already built.

The wall was built by day labor, under the direction of J. B. Bassett, M. Am. Soc. C. E., U. S. Assistant Engineer, Rock Island, Ill. We are indebted to Mr. Bassett for the data from which this analysis of costs has been prepared. The dam was a portion of the Mississippi Improvement work at Moline, Ill.

Cost of Puddle.—Puddle is a mixture of gravel and clay which is wet and rammed or rolled into place. Many engineers use the clay as they would a mortar to fill the voids in the gravel. A few engineers use the gravel merely to insure the crumbling of the sides and roof of any incipient hole in the puddle so as to fill it up.

Fanning gives the following proportions measured loose:

	Cu. yd.
Coarse gravel	1.00
Fine gravel	0.35
Sand	0.16
Clay	0.20
Total loose	1.70

This when mixed, he says, will make 1.3 cu. yds., and when thoroughly rammed 1.25 cu. yds.

Another mixture given is:

	Cu. yd.
Gravel	1.00
Sand	0.35
Clay	0.25
Total	1.60

This when mixed and spread makes 1.16 cu. yds., and when rammed 1.1 cu. yd.

When clay is not available, very fine sand and a little loam can be used to fill the voids in gravel. Where puddle is used to cover

a large area, like the bottom of a reservoir, the gravel is first spread in a layer about 3 ins. thick, the clay is spread over the gravel, and the sand over the clay in their proper proportions. Then an ordinary harrow is dragged by a team back and forth until mixing is complete. Water is next sprinkled over in amount sufficient to cause the mass to knead like stiff dough under a $2\frac{1}{2}$ -ton rolling tamper or under a 2-ton sectional roller. Such a puddle is as heavy as concrete and resists abrasion almost as well. With labor at \$1.50 and teams at \$3.50, the cost is about as follows:

	Per cu. yd.
Spreading by hand	8 cts.
Harrowing	5 cts.
Sprinkling	2 cts.
Rolling	5 cts.
Total	20 cts.

An exacting engineer, however, can readily double this cost, bringing it to 40 cts. per cu. yd., which is about what it costs to spread, sprinkle and roll a cu. yd. of macadam road.

Where puddle is used in confined places, like trenches, it must be mixed like concrete and rammed to place, the cost then being 30 to 50 cts. per cu. yd. On the Erie Canal, in 1896, with wages at \$1.50 for 10 hrs., the contract prices for mixing and laying puddle ranged from 30 to 60 cts. per cu. yd., the average price being 35 cts. per cu. yd., exclusive of the materials.

Cost of Sheet piling and Bracing a Small Circular Reservoir.—Mr. George A. Rogers gives the following relative to the cost of sheet piling and bracing a circular pit excavated for a reservoir at Kinston, N. C., in 1905:

The reservoir is 60 ft. inside diam., 20 ft. deep, and holds 15 ft. of water, or 350,000 gals. The sides and bottom are lined with brick, of which 200,000 were required. The brick side walls are 12 ins. thick at the top and 36 ins. at the bottom. The bottom lining is 6 ins. thick, being three layers of brick laid flatwise.

The first 5 ft. were excavated with drag scrapers; below that the material was a running sand which was loaded by hand into skips. The sheet piling was 2 x 8 ins. x 18 ft., plank dressed on three sides. It was held by three rings (70 ft. diameter) of rangers (8 x 8-in.) encircling the pit; which were held in line by 8 x 8-in. posts, 4 ft. long, spaced 5 ft. apart and bolted to the rangers. The rangers were 12 ft. long, mitred at the ends and with joints bolted.

The cost of this timber work was as follows:

10,000 ft. B. M., at \$10.....	\$100 00
Iron	30 00
6 days carpenter, at \$2.50.....	15 00
12 days helper, at \$1 00.....	12 00
Total	\$157 00

This labor cost includes framing and assembling the rings and braces, but not the driving of the sheet piling. There were about 6,000 ft. B. M. of rangers and braces, so that this framing and erecting cost \$4.50 per M.

A ditch was dug all around the inside of the sheeting to lead the ground water to a sump whence it was raised by a plunger at the rate of 450 gals. per min.

By this style of circular ring bracing, not only was very little timber required (4 ft. B. M. per cu. yd. of pit enclosed by sheeting), but the pit was left entirely open.

Cost of Dams Per Million Feet of Water Stored.—It is not unusual for hydraulic engineers to compare the cost of small reservoirs in terms of the cost per million gallons of water stored, and, in like manner, to compare large reservoirs or dams in terms of the cost per million cubic feet of water stored. The cost of small artificial reservoirs, made by throwing up banks of earth excavated from the interior, can be compared in this way with some rough degree of accuracy, but a little consideration shows how absurd it is thus to compare large reservoirs made by building a dam across a natural valley. How much water a dam will impound depends far less upon the size, and therefore upon the cost, of the dam than upon the topography of the valley above the dam. The following tabulation brings out this fact very clearly:

Dam.	Height ft.	Masonry cu. yds.	Cost.	Cost per 1,000,000 cu. ft. stored.
New Croton, N. Y.....	297	833,000	\$7,600,000	\$1,900
Wachusett, Mass.....	207	280,000	2,000,000	238
Roosevelt, Ariz.	280	350,000	3,850,000	63
Shoshone, Wyo.....	308	69,000	1,000,000	50
Pathfinder, Wyo.....	210	53,000	1,000,000	23

Cross References on Dams and Reservoirs.—The following sections of this book contain data on dams: Earth Excavation and Embankment, Stone Masonry, Concrete Construction. Consult the Index under Dams and under Reservoirs.

Waterworks Valuation and Plant Depreciation.—A very complete discussion of this subject by Leonard Metcalf is given in *Engineering-Contracting*, Dec. 16 and 23, 1908, and Jan. 6 and 13, 1909. Mr. Metcalf gives also an excellent compendium of legal decisions and a very full bibliography of articles bearing upon valuations.

Figs. 29 and 30 give the depreciated value when estimated by the sinking fund formula of depreciation, for a discussion of which consult Section I, of this book. See the index under Depreciation.

Table XVI gives the life and annual contributions to the sinking fund to cover depreciation.

"Going Value" of Waterworks.—A discussion of this subject by John W. Alvord, with data and illustrative diagrams, will be found in *Engineering-Contracting*, Aug. 4, 1909.

A discussion of the subject by Chas. B. Burdick is also given in *Engineering-Contracting*, Oct. 23, 1907.

Life of Cast Iron Water Pipe.—Regarding the life of cast iron water pipe, Mr. John W. Alvord says:

"It is generally conceded that cast iron pipe of hard, light-gray, close-grained iron of even texture, properly coated with good preservatives, laid in ordinary soils and conveying water of average quality, has a life that we have as yet no reliable data to determine, because a sufficient amount of it has not, as yet, lived its life, and we can only approximate what a fair average may be. The uncoated pipe first laid in England and this country about 100 years ago (1803) are every now and then taken up and exam-

TABLE XVI.

	Useful life. Years.*	Annual contribution to De- preciation Account or Sink- ing Fund in per cent of cost.	
		At 5% annual rate sinking fund. Per cent.	General approximate results. Per cent.
Reservoirs	50-100	0.4777-0.0382	$\frac{1}{2}$ -0

Electrical machinery	20-30	3.0243-1.5051	4-2
Average for entire plant (gravity system)			1% to $\frac{1}{2}$ %
Average for entire plant (pumping system)			2% to 1 $\frac{1}{2}$ %

*Except where subject to heavy deposit of silt.

ined with the result that while always found to be filled with the result of oxidation and tuberculation to a serious degree the actual body of the iron, although somewhat brittle, does not seem to have been seriously diminished in thickness."

"The coating process of Dr. Angus Smith was first introduced into this country in 1858, and by 1869 the method of coating by coal tar varnish was generally adopted, with great resulting benefit, preserving the life and carrying capacity of the cast iron pipe in a manner and to an extent which, as has been before said, is still to be determined by future observations."

Life of Pipe Wrought Iron Pipe, Lowell, Mass.—In the Proceedings of the American Water Works Association, 1894, page 181 et seq., are given some data as to the corrosion of iron and steel. An instance is cited of a wrought iron pipe, $\frac{1}{4}$ in. thick, laid at the Merrimack Co.'s Mills, Lowell, Mass., in 1845. A piece was cut

Age in Years.

Fig 29.—Depreciation Curves.

Age in Years.

Age in Years.

Fig. 30. — Depreciation Curves.

Age in Years.

out in 1887, and it was evident that the pipe was good for another 40 years. The outside and inside of the pipe had originally been coated with coal tar. The conditions of soil and water were exceptionally favorable.

Life of Pipe in Salty Soil.—In the Proceedings of the American Waterworks Association, 1899, page 103, Mr. S. Tomlinson says that a 32-in. cast iron pipe, laid in an embankment across land washed by the ocean tides, was badly corroded in 10 years, and after 36 years is unfit for further use, in many places the iron being converted to oxide $\frac{1}{2}$ to $\frac{3}{4}$ in. in thickness, leaving a mere shell of solid iron.

In the Proceedings of the Institution of Civil Engineers (Great Britain), Vol. 143 (1901), p. 259, Mr. William Wark says that wrought iron service pipes lasted only 7 years at Hay, whereas such pipes were still in good condition after 27 years' service at Bathurst. The soil at Hay is of a light sandy nature, containing large quantities of salt. The soil at Bathurst is of a rotten granite nature. Cast iron water mains at Hay show no signs of injury, but wrought iron gas mains lasted only 11 years.

Life of Pipe, St. John, N. B.—Mr. Gilbert Murdoch gave, in 1892, the following relative to the life of cast iron pipe at St. John, N. B.:

A 4-in cast iron pipe, 33 yrs. old, buried in marsh mud, burst under a pressure of 65 lbs. per sq. in. The outside of the pipe had undergone a softening at the break, which was along some air cells in the body of the shell.

A 6-in pipe, 52 yrs. old, in soft, slaty rock failed. The pipe was as easily cut as plumbago.

A 24-in. pipe, 36 yrs. old, in well drained, gravelly brick-clay, failed.

The Life of Pipe and Appraisal of Syracuse Waterworks.—Mr. Stephen E. Babcock gives the following relative to the life of cast iron pipe. In 1891, in the city of Syracuse, N. Y., condemnation proceedings were undertaken preliminary to the purchase of the waterworks owned by a private company. The engineering experts for the water company dug up sections of pipe and tested it in the presence of the court. Uncoated cast iron pipe that had been laid 40 years was found to be apparently as perfect as when first laid; it had become coated neatly and uniformly with a coating not exceeding $\frac{1}{64}$ th of an inch thick. It stood a pressure of 700 lbs. per sq. in. The water is unusually hard. Cement lined pipe (with a wrought iron core) was also dug up and tested, sizes being 4 to 10-in. It stood 300 lbs. per sq. in., and where the cement was removed the iron appeared as perfect as when laid in 1862.

The experts for the city claimed that practically no value should be assigned to existing 4 in. and 6 in. pipes, as they were too small. In rebuttal it was shown that the mileage of pipes of these sizes was as follows in different cities:

	Per cent.
Syracuse, N. Y.	62
Rochester, N. Y.	70
Waltham, Mass.	81
Fitchburgh, Mass.	76
Erie, Pa.	90
Washington, D. C.	85
Schenectady, N. Y.	87
Cincinnati, O.	66
Binghamton, N. Y.	74
Port Huron, Mich.	75

As the reservoir had been built many years before, all records of the amount of excavation, etc., had been lost. The experts for the water company submitted evidence to show what similar reservoirs had cost per million gallons of storage capacity, as being the only rational means of arriving at the value of this reservoir whose capacity was known.

Estimated Depreciation of Water Pipe, Los Angeles, Calif.—In estimating the depreciation of water pipes in Los Angeles, Calif., a board of four engineers (Jas. D. Schuyler, A. L. Adams, A. H. Koebig and J. P. Lippincott) adopted the following rates of annual depreciation, for purposes of appraisal of present value:

Cast iron pipe in good soil.....	1.25
Cast iron pipe in poor soil.....	2.00
Sheet iron pipe in good soil.....	4.00
Sheet iron pipe in poor soil.....	6.77
Wrought iron pipe in good soil.....	3.33
Wrought iron pipe in poor soil.....	5.71

These depreciations were applied to the cost of the pipe in place (including pipe, lead, labor of laying, removing and replacing pavement, etc.) Soils ranging from salty shales and alkaline adobe (clay) to heavy clay were classed as "poor," and the balance as "good." After deducting the above depreciation from the first cost, a further depreciation, called internal depreciation due to tuberculation, was calculated on those depreciated values and deduced therefrom. The annual internal depreciation was estimated as follows:

	Per cent. Per year.
Cast iron pipe, 4 in. and over.....	0.6
Cast iron pipe, 3 in. for less than 10-yr. of age...	2.0
Cast iron pipe, 3 in. for over 10 yrs. of age.....	1.0
Sheet iron and steel	0.75
Wrought iron, under 4 ins., for less than 10 yrs. of age	2.00
Wrought iron, under 4 ins., for over 10 yrs. of age...	1.00
Wrought iron, 4 ins.....	1.50

SECTION VIII.

SEWERS, CONDUITS AND DRAINS.

General Considerations.—Trenches for sewers are usually much deeper than trenches for water pipes, because it is generally desirable to have a sewer deep enough to drain cellars and basements. In cities a common depth of trench is 8 to 11 ft. If the depth is more than about 6 ft., even in narrow trench work, men will be required on the surface to shovel the earth back from the edge of the trench after it has been cast up. In such cases always cast the earth onto plank, for reasons given in Section 2 on Earthwork. When the depth much exceeds 8 ft., it is advisable to cast the earth out of the trench in stages, using platforms about 6 ft. apart—or less if the earth is sloppy. Bear in mind that where the trench is a wide one, there is much handling of the earth after it reaches the surface, both in stacking it up in pile and in moving it back into the trench ("backfilling") after the sewer has been laid. In large sewer construction there is more excavation than backfill, and the excess must be loaded and carted away. Each case must be estimated separately, which can be done with the data given in Section 2 on Earthwork, and with the data in this section and in the previous section on Waterworks.

Deep trenching is beset with so many difficulties, such as the handling of unexpected bodies of water, the caving of banks even when well sheeted, and the like, that liberal estimates of cost should always be made. Then \$7 to \$10 a day should ordinarily be added for rental of a trench machine, for even where owned by the contractor a liberal allowance must be made for wear and tear and interest, since so much of the time the machine is ordinarily idle. The cost of the sheeting plank and bracing must be added, also that of pumping, if the soil is wet. In many localities glacial boulders are likely to be encountered, greatly delaying work and adding to the cost.

Accidents to men are frequent—so much so in some cities that accident insurance companies absolutely refuse to insure a sewer contractor's men. Accident insurance is seldom less than 1% of the pay roll, even on safe work, and on sewer work it often runs up to several per cent.

Cost of Sheet piling at Peoria, Ill.—On a trench 12 ft. wide X 45 ft. deep, at Peoria, Ill., sheet piling in 16-ft. lengths cost as follows for labor:

2 men on top, at \$2.....	\$4
2 men setting sheeting, at \$2.50.....	5
8 men driving sheeting, at \$1.50.....	12
8 men pulling sheeting, at \$1.50.....	12
2 men moving lumber ahead, at \$1.50.....	3

Total daily wages of gang..... \$36

This gang sheeted 12 lin. ft. of trench per day at a cost of \$3 per lin. ft., all work being by hand; this is equivalent to 6½ cts. per lin. ft. of trench for each foot of depth. If 2-in. sheet plank were used, there were 192 ft. B. M. of sheet plank per lin. ft. of trench and probably 38 ft. B. M. of stringers and braces, say 230 ft. B. M. per lin. ft. From which we see that driving and pulling sheeting, including bracing, cost for labor about \$13 per M (= 1,000 ft. B. M.) at the rate of wages above given, which is a high cost.

The cost of exactly the same kind of work, using an Adams' trench machine with steam power for driving and pulling the sheeting, was as follows:

2 timber men on top, at \$2.....	\$4.00
2 men setting, at \$2.50	\$5.00
1 man operating driver.....	2.00
2 helpers, at \$1.50.....	3.00
1 man pulling	2.00
2 helpers, at \$1.50.....	3.00
1 engineer	2.00
1 man moving lumber ahead.....	1.50
Coal, oil, steam hose and repairs.....	2.50

Total\$25.00

Twelve lineal feet of trench, 45 ft. deep, were timbered per day at this cost of \$25, or at \$2.08 per lin. ft., which is practically ⅓ the cost by hand above given, and in addition the wear of the sheet plank was less than with hand driving.

The following cost of sheeting is for hand work, trench being 12 ft. wide X 35 ft. deep:

2 timber men on top, at \$2.....	\$4.00
1 man setting	2.50
6 men driving, at \$1.50.....	9.00
4 men pulling, at \$1.50.....	6.00
1 man moving lumber.....	1.50

Total\$23.00

At this cost, 13 lin. ft. of trench were sheeted per day, or at the rate of \$1.77 per lin. ft.

Smaller trenches, 8 ft. to 16 ft. deep in sand, cost from 10 to 25 cts. per lin. ft. for labor of sheeting with 2 x 7-in. hemlock. Stringers in trenches 35 ft. or more deep were 8 x 8 ins. yellow pine, with 6 x 8-in. white pine braces. In trenches of less depth 6 x 6-in. hemlock stringers and braces were used. The above costs do not include wear and tear on timber. Some sewer contractors figure on using hemlock sheeting about 4 times, with hand-driving, before it is worn out.

Cost of Pumping Water From Trenches.—The cost of pumping water from trenches is given by Mr. Elliot C. Clarke as follows for three kinds of wet trenches, namely, "slightly wet," "quite wet" and "very wet."

In a "slightly wet" trench one hand pump was used.

In a "quite wet" trench one steam pump and a line of 8-in. pipe was used, sumps or wells being 500 ft. apart; the rent of this plant is rated at \$3 a day; the engineman \$2.50 a day; the price of fuel is not given.

In a "very wet" trench two steam pumps and wells every 250 ft. were used; three enginemen.

The cost of pumping per lineal foot of trench was as follows:

Depth of trench, ft.....	5	10	15	20	25
Slightly wet, cost per ft.....	\$0.06	\$0.07	\$0.10	\$0.12	\$0.13
Quite wet, cost per ft.....	0.71	0.73	0.76	1.04	1.27
Very wet, cost per ft.....	1.17	1.19	1.26	1.64	2.26

Cost of Trenching With Trench Excavators.—Mr. Ernest McCullough gives the following data relating to work done by the "Chicago Trench Excavator"—a machine made by the Municipal Engineering and Contracting Co.

The machine consists of an endless chain provided with cutters and scrapers which deliver the earth onto a traveling belt, the excavators and conveyors being carried by a four-wheeled traction engine, which furnishes the power. These machines are rented or sold to contractors.

In laying 7½ miles of pipe sewers at Marshfield, Wis., the daily cost of operating the machine and laying pipe was as follows:

Operator of trench digger.....	\$ 3.00
Engineman of trench digger.....	2.75
Fireman of trench digger.....	2.25
Man trimming bottom of trench.....	2.25
2 men bracing trench with plank.....	4.00
2 pipe layers, at \$2.50.....	5.00
2 men furnishing pipe and mortar.....	4.00
2 men tamping earth around pipe.....	4.00
1 man shoveling earth down to the tamper.....	2.00
2 teams and drivers scraping backfill.....	7.50
4 men holding the scrapers.....	8.00

Total labor per 10-hr. day.....\$44.75

About ¾-ton of coal was used daily.

The trench was 27 ins. wide and averaged 7 ft. deep. The best day's run was 850 lin. ft. of trench, or 500 cu. yds. in 10 hrs., in dry clay containing no stones. On another day nearly 500 ft. were run in spite of many stops to blast out boulders. A fair average was 400 to 500 lin. ft., or 300 cu. yds. per day. Due to the jarring of the ground by the machine it is necessary to brace the trench.

(I am informed by Mr. McCullough that records of 650 cu. yds. per day have recently been made with this machine.)

These trench excavators are made in four sizes to excavate from 14 ins. to 60 ins. in width and up to 20 ft. in depth.

As confirming these data of Mr. McCullough's, the following records given by Mr. B. Ewing are of value. In the summer of 1904, many miles of pipe sewers were built at Wheaton, Ill., by contract. Two Chicago Excavators were used, cutting a trench $2\frac{1}{2}$ ft. wide, 7 to 18 ft. deep. One machine would excavate 750 lin. ft. of trench 7 ft. deep through hard clay mixed with small stones, in a 10-hr. day. In cutting trenches 15 to 18 ft., a machine would average 150 to 200 lin. ft. per day, depending upon how much bracing was necessary.

See page 651 for data on the cost of trenching with a Buckeye Traction Ditcher.

Cost of Excavating With Trench Machines.—A trench machine, as the term is here used, does not mean an earth digger, but an earth conveyor. The Carson trench machine is a good example of the type. It consists essentially of a single rail track on which a trolley travels, being hauled back and forth by the cables of a hoisting engine. The trolley carries the bucket into which the earth or rock has been loaded by hand. The single rail track is supported at intervals by a light trestle made of bents that are A-shaped.

The legs of the A-bents are provided with wheels at the bottom riding on a track straddling the trench, and the whole trestle can be moved forward in 5 to 10 mins., from time to time, as the work advances, without taking the trestle apart, unless a curve has to be rounded. These A-bents are of 6 x 8-in. spruce, 20 ft. high and have a spread of 18 ft. at the bottom. The trestle is 288 ft. long, and buckets of 1 cu. yd. each are handled. The crew and the cost of operation are the same as for a cableway.

Mr. A. W. Byrne states that in completing one 4,000-ft. section of the Metropolitan sewer system, at Boston, he used the following force.

1 engineman	\$ 3.00
1 lockman	2.00
1 dumper	1.50
2 shovelers, at \$1.75	14.00
2 bracers, at \$2.50	5.00
2 tenders, at \$2.00	4.00
4 plank drivers, at \$2.00	8.00
2 men cutting down planks, at \$2.00	4.00
3 men pulling planks, etc., at \$1.75	14.00
Total	\$65.50

The force working in a trench 9 ft. wide x 20 to 30 ft. deep averaged 64 lin. ft. a week in "bolting sand," the pressure of which would break 6 x 8-in. stringers $2\frac{1}{2}$ ft. apart, and 192 ft. a week in gravel and coarse sand, which is equivalent to 70 to 110 cu. yds. a day in the running sand, and 200 cu. yds. in good ground, or at a cost ranging from 80 to 25 cts. cu. yd. A steam pump running at a cost of \$10 a day was also required, and about $\frac{1}{2}$ -ton of coal

was used by the trench machine. The work mentioned was done after the trench machine was set up, and the gang well organized. Another contractor states that it took him two days to dismantle a machine, move it 1,000 ft. and set up again.

The Adams trench machine consists of a series of wrought-iron Π -shaped bents, the lower feet of the Π being provided with wheels running on rails laid each side of the trench. These Π bents carried two rails, on each side, beneath the top of the bent, and a car ran along these rails; this car is pulled back and forth by cables from a hoisting engine at one end of the trench; and the same engine raises buckets up to the car where they are gripped. Working in sand at Peoria, Ill., the following was the cost in a trench 13 ft. wide x 45 ft. deep:

	Per day.
18 men loading buckets, at \$1.50.....	\$27.00
1 man operating bucket car.....	2.00
1 foreman	3.00
1 engineman	2.50
1 waterboy50
Coal, oil, etc.....	1.00
Total per day.....	\$36.00

This force excavated 284 buckets of 1 $\frac{1}{8}$ cu. yds. each, of 318 cu. yds. daily at a cost of 11.4 cts. per cu. yd., as the average of 1 month.

The same gang operating in a trench, 12 ft. wide x 33 ft. deep, averaged 288 buckets a day, at a cost of 12.5 cts. per cu. yd. Most of the excavated material was dumped directly from the buckets as backfill into the trench where the sewer was completed.

A Moore Hoister and Conveyor, which differed only in having the bucket car travel on top of the bent, instead of below, required one more man handling the buckets, making the daily force account \$38. In a trench 12 ft. wide x 35 ft. deep the Moore machine daily averaged 286 buckets of 1 cu. yd. each, at a cost of 13.3 cts. per cu. yd.

These records for Adams and Moore machines show unusually low costs. They should not be taken as averages, but rather as showing the very best that can be done under favorable conditions. Mr. A. D. Thompson is my authority for these cost records. The cost of sheeting these trenches is given on pages 435 and 436.

Cost of Trench Excavation in Massachusetts, Using a Carson Machine.—Mr. H. H. Carter gives the following account of work done by contract in Massachusetts in 1884: A trench 2,100 ft. long, 9 $\frac{1}{2}$ ft. deep and 20 ft. wide was dug for a conduit along the shore of a pond and about 30 ft. away from the water's edge. The water in the pond was 8 ft. higher than the bottom of the trench, but most of the water that entered the trench seeped in from the side farthest away from the pond. The water was handled by two Pulsometer Steam Pumps. A large quantity flowed in at some places. All water was pumped from sumps located ahead of the

laying of the brick conduit. No underdrains were left under the finished conduit. The material excavated was variable. The greater part of the conduit was built on a hard, coarse sand and gravel bottom; but for several hundred feet quicksand was encountered in the bottom. A Carson trench machine was used for 10 weeks. The total excavation was 15,100 cu. yds., or 7.2 cu. yds. per lin. ft. of trench. The backfill amounted to only 15 cu. yds. per lin. ft. of trench. The itemized cost was as follows for 2,100 ft., or 15,100 cu. yds.:

	Total.	Per cu. yd.
Foreman, 66 days, at \$4.00.....	264.00	\$0.044
Foreman, 169 days, at \$2.50.....	397.50	
Engineer, 123 days, at \$2.50.....	307.50	0.020
Fireman, 147 days, at \$1.75.....	257.25	0.016
Pumpman, 94 days, at \$3.00.....	282.00	0.026
Pumpman, 56 days, at \$1.75.....	98.00	
Laborer, 2,400 days, at \$1.25.....	3,000.00	0.200
Laborer, 2,200 days, at \$1.50.....	3,300.00	0.220
Bracer, 366 days, at \$1.76.....	640.50	0.042
Carpenter, 7 days, at \$2.00.....	14.00	0.001
Horse and cart, 88 days, at \$4.00.....	352.00	0.023
Horse and cart, 10 days, at \$3.15.....	31.50	0.002
Scraper, 71 days, at \$5.00.....	355.00	0.024
Carson machine, 10 weeks, at \$45.00.....	450.00	0.030
Engine, 103 days, at \$2.00.....	206.00	0.014
Boiler, 129 days, at \$1.00.....	129.00	0.008
Pumps (two), 199 days, at \$0.80.....	159.20	0.011
Derrick, 72 days, at \$1.00.....	72.00	0.005
Tools	71.00	0.005
Coal, 80 tons, at \$6.00.....	480.00	0.032
Sheeting, loss on, at \$14 per M.....	200.00	0.013
Iron, at 3 cts. per lb.....	15.00	0.001
Miscellaneous	26.00	0.002
Total	\$11,107.45	\$0.740

The backfilling and embankment cost is included in the above cost of 74 cts. per cu. yd. of trench excavation. Properly it should be separated, as follows:

	Per lin. ft.
Excavating trench	\$3.20
Bracing trench, labor.....	0.30
Bracing trench, lumber.....	0.10
Pumping trench	0.46
Backfilling	0.71
Embankment	0.69
Miscellaneous	0.28
Total, per lin. ft.....	\$5.73

Deducting the backfilling and embankment, we have left \$4.33 per lin. ft., or 60 cts. per cu. yd. of trench. The backfilling itself cost 18 cts. per cu. yd. backfilled.

This same trench work was extended across a pond that had been filled with an embankment of gravel and sand from a trestle. The trench was excavated in the center of this embankment, and was 18 ft. wide, with sheet piles on both sides, and its bottom was 6 ft. below the level of the pond. The water was handled by two pulsometers and one Andrews pump. The trench was 1,550 ft. long.

containing 8,070 cu. yds. and took 125 days to excavate. The itemized cost was as follows:

	Total.	Per cu. yd
Foreman, 35 days, at \$3.50.....	\$ 122.50	\$0.015
Foreman, 150 days, at \$2.50.....	375.00	0.047
Engineman, 146 days, at \$2.50.....	465.00	0.058
Pumpman, 286 days, at \$1.75.....	500.50	0.062
Laborer, 400 days, at \$1.65.....	660.00	0.085
Laborer, 460 days, at \$1.50.....	690.00	0.086
Laborer, 2,500 days, at \$1.25.....	3,125.00	0.388
Bracer, 255 days, at \$1.75.....	446.25	0.056
Horse and cart, 12 days, at \$3.15.....	37.80	0.004
Engines, 125 days, at \$2.00.....	250.00	0.031
Boiler, 125 days, at \$1.00.....	125.00	0.015
Pulsometers, 223 days, at \$0.80.....	178.40	0.022
Pump (Andrews), 67 days, at \$2.00.....	134.00	0.017
Derricks, 125 days, at \$1.00.....	125.00	0.015
Tools	57.00	0.007
Coal, 52 tons, at \$6.00.....	312.00	0.039
Spruce, 49 M left in, at \$14.00.....	686.00	0.086
Miscellaneous	85.00	0.004
Total (1,550 lin. ft.).....	\$8,344.45	\$1.032

This cost of \$1.03 per cu. yd. includes some but not all of the backfilling. The cost per lin. ft. was distributed as follows:

	Per lin. ft.
Excavating	\$3.25
Bracing, labor	0.29
Bracing, lumber	0.45
Pumping	0.72
Backfilling and embankment.....	0.66
Total	\$5.37

Deducting the backfilling we have \$4.71 per lin. ft., which is equivalent to 90 cts. per cu. yd. of trench. The backfilling itself cost 19 cts. per cu. yd. backfilled. The contractor's price was less than half what the work cost him, but it appears evident that he did not manage his work very well.

Cost of Excavating With a Potter Trench Machine.—The following data were published in *Engineering-Contracting*, April, 1906, and January 28, 1908. Fig. 1 shows a Potter trench machine, made by the Potter Mfg. Co., Indianapolis, Ind. The machine consists of a track supported by bents that span the trench. On this track travels a carriage having drums for hoisting the buckets of earth from the trench. The track is ordinarily 270 ft. long, the hoisting engine being located at one end. Two men ride on the carriage to handle the buckets. Buckets loaded by hand are lifted from the trench by the machine and carried back and dumped on the completed sewer for backfill.

Certain sections of an intercepting sewer were built by day labor in Chicago, during 1901-1903. A Potter trench machine 370 ft. long was used. An ordinary double drum hoisting engine was placed at the front end of the machine. By means of two cables and a series of drum sheaves, the engine hoisted the bucket and moved the carrier along the trackway as required. The entire ma-

chine, including the engine, was supported on track on each side of the trench. After the track was built, 5 min. was ample time in which to move the whole machine 48 ft., that amount of trench being worked at a time. The Potter trench machine was used to remove the clay and about 2 ft. of overlying sand.

In the excavation six $\frac{3}{4}$ -yd. buckets were used, four in the trench and two on the carrier. Two empty buckets were placed in adjoining sections and two full ones removed on each trip. The trench machine crew consisted of the following: One hoisting engineer, one fireman, and two carrier men. The number of bottom men or diggers ranged from 17 to 21, depending on the

Fig. 1. Trench Machine.

kind and amount of excavation. In addition, the track supporting the machine was built by a gang of timber men, whose other duties were the removal of braces, and miscellaneous work.

The rates of wages of the trench machine crew were as follows:

	Rate.	Total.
1 foreman	\$4.00	\$ 4.00
2 engineers	4.80	9.60
1 fireman	2.75	2.75
2 carrier men	3.75	7.50
17 bottom men	3.25	55.25
Total daily labor		\$79.10

Note that the wages of laborers were very high.

One ton of coal, costing \$2.90, per day was used; adding this to

the total labor cost and we get \$81. About 190 cu. yds. were excavated each day, so the cost, per cu. yd., was 42.2 cts. per cu. yd., exclusive of plant rental, and cost of laying track.

During 1906, there were 2,440 lin. ft. of concrete sewer (5½ ft. diam.) built by contract for the city of South Bend, Ind.

The section of the city through which this sewer was built was flat and marshy. The material, in consequence of this, was loose black soil for a depth of about 4 ft. Then sand and gravel were encountered, and for the last 4 or 5 ft. of the trench this material was water soaked. This made pumping necessary in the excavation work and also during the progress of the concrete construction.

The trench was 10½ ft. wide, and 18 ft. was the average depth. This gave 7 cu. yds. of excavation per lin. ft. of trench. Shoring of the sides of the trench was necessary. The first 2 or 3 ft. of the trench was excavated either by men casting the material from the trench or was plowed and moved with scrapers.

After this much excavation was done a Potter trench machine, manufactured by the Potter Manufacturing Co., Indianapolis, Ind., was installed and used for all the work of excavation and for handling the concrete.

The trench machine was used to excavate from 5 to 6 cu. yds. per lin. ft., but, as no separate record was kept of the first excavation done, the entire cost of the excavation is figured as done with the machine.

It is stated that the carriage that handled the buckets could make a round trip in one minute, including the time of lowering and hoisting the buckets. The following data were furnished by Mr. W. A. Morris, Asst. City Engineer of South Bend.

On the work described it was the custom to keep about 100 ft. of the trench open at one time. The material was taken from in front of the sewer and dumped on the completed portion. The excavation on top was dry, but as it neared the bottom, as previously stated, water was encountered. The following system of drainage was used. The water came from the gravel and sand. A sub-drain pipe was laid of second class and cull pipe, the bottom of this being laid 30 ins. below the grade of the invert of the sewer. The joints were loosely caulked with tufts of sod in order to prevent the fine sand from entering the pipe. Clean gravel of medium size covered the pipe. This permitted water to enter the pipe, through which it flowed to a sump at the lower end of the new work. This sump was 18 ins. below the grade of the drain pipe, and the water was pumped from the sump by a 6-in. rotary pump over a dam into the old portion of the work.

This drained the bottom of the trench so that the concrete was readily laid, and by keeping the pump going continually, allowed the concrete to set without being injured by the water rising in the trench. This pumping and drainage work is included in the cost of excavation but a part of it could properly have been charged against the concrete work.

The wages paid for a 10-hr. day were as follows:

Engineer on trench machine.....	\$3.00
Fireman on trench machine.....	1.65
Engineer for pumping	2.00
Fireman	2.50
Carpenter	2.50
Laborers	1.85

The cost of the various work per lin. ft. of trench was as follows:

Pipe for sub-drain	\$0.33
Labor laying this pipe.....	0.35
Pumping water	0.45
Excavation and backfilling.....	2.80
Setting and pulling shoring.....	1.04
Allowance for tools and gen. ex.....	.25
Total per lin. ft.....	\$5.22

With 7 cu. yds. per lin. ft. of trench this makes a cost per cu. yd. of excavation for each of the above items as follows:

Pipe for sub-drain.....	\$0.047
Labor laying this pipe.....	0.050
Pumping water	0.065
Excavation and backfilling.....	0.400
Shoring	0.150
Tools and general expenses.....	0.035
Total per cu. yd.....	\$0.747

The drainage, it will be noticed, cost a little more than 20 per cent of the total. The cost of excavation and back filling, and of shoring and filling the street piles for a trench as deep as this is quite reasonable.

Cost of Excavating With Potter Trenching Machine for 16-ft. Sewer.*—The final section of the conduit work proper for the Lawrence avenue sewer at Chicago, Ill., includes the construction of 1,150 lin. ft. of 5-ring, 16 ft. diameter brick conduit from the north branch of the Chicago river to the section completed in 1901 by Farley & Green. The sewer will empty in the north branch, which is being dredged to a width of 90 ft. ultimately this width will be increased to 180 ft.

The excavation was done by the open cut method, the width of the trench being 21 ft. and the average depth being 30.5 ft. The materials encountered in the excavation consist of a top layer of black soil, then come about 15 ft. of soft blue clay, 6 to 8 ft. of stiff blue clay, 1 ft. of sandy loam and about 2 ft. of hard blue clay. This latter was so hard in places that its removal was facilitated by "shooting."

The first 16 to 18 ft. of excavation was done with the aid of skips and a derrick of the Kearnes type, having a 55-ft. boom and equipped with a 7 x 10 double drum hoisting engine. The derrick is so arranged that the boom can swing in a half circle on either side of the trench. The framework carrying the turntables spanning the trench rests on shoe timbers, these in turn resting on rollers. A runway is built ahead of these rollers, and the derrick

**Engineering-Contracting*, Oct. 9, 1907.

is pulled ahead by means of ropes wound round the nigger head of the engine and single and double blocks. The skips are of 1 cu. yd. capacity, were filled by hand shovelling, lifted by the derrick and swung to one side of the trench, the spoil being used for filling low places, or later for completing the backfilling. As the excavation proceeds, a 2-in. plank sheeting is placed and carried down to a depth of about 14 ft., 8 x 10-in. timber spaced 20 ft. centers being used for bracing.

A Potter trenching machine followed the derrick and skips, and was used in carrying down the excavation to the required depth. Six $\frac{1}{2}$ cu. yd. capacity buckets are used with this machine, there always being four buckets in the trench being filled, while the remainder are being carried back on the carriage and dumped on the completed brick work. The hardest part of the excavation was done with this machine, the clay being sticky and tenacious and coming away in hard lumps. An average of 175 to 200 cu. yds. was excavated each day with this machine.

The wages per 8-hour day and number of men employed in excavating with the Potter trenching machine were about as follows:

	Per day.	Total.
Engineer	\$6.00	\$ 6.00
Fireman	2.50	2.50
1 man on carriage.....	2.50	2.50
1 man on carriage.....	3.25	3.25
20 bottom men	2.75	55.00
1 man on dump	2.75	2.75
Foreman	3.50	3.50
Total		\$75.50

One-half ton of coal was consumed each day by the machine, allowing \$2.50 for this and assuming that the rent of the machine was \$125 per month (\$4.80 per day) the total cost per 8-hour day would be \$82.80. On the basis that 175 cu. yds. of material was excavated each day, the cost would be about 47 cts. per cubic yard.

The bricklayers follow the trenching machine, six masons working to a shift. About 1,700 brick were used per foot of sewer, the average rate of progress being 16 ft. of sewer completed per day. This means that one bricklayer puts in place 4,500 brick per day, at a cost for his labor, in the wages at \$6 per 8 hours, of \$1.33 per thousand of brick, or about \$2.65 per cubic yard of masonry. This, of course, does not include bricklayers' helpers, cost of materials or centers.

The work, which was completed recently, was done by the American Engineering & Construction Co. of Chicago, of which Mr. W. A. Shaw is president.

Cost of Excavating With Trench Machine.—In *Engineering Contracting*, April, 1906, the method of excavating a sewer in Chicago with a Potter trench machine is illustrated and described. The machine was 370 ft. long, and was moved forward 48 ft. at a time, only 5 minutes being required to make a move. The crew for moving and operating the machine was:

	Per day.
1 foreman	\$ 4.00
2 enginemen at \$4.80.....	9.60
1 fireman	2.75
2 carrier men at \$3.75.....	7.50
17 bottom men at \$3.25.....	55.25
Total labor.....	\$78.10
1 ton coal.....	2.90
Total, 190 cu. yds. at 40.2 cts.....	\$81.00

Note that the laborers were paid very high wages. They were working for the city.

Cost of Trenching by Cableways.—A cableway consists essentially of a main cable suspended between two towers, and serving as a track for the trolley carrying the loaded bucket, which is pulled back and forth by small cables from a stationary hoisting engine. The following data will give a good idea of what can be done with a cableway.

Parallel with a railroad track a trench 14 ft. wide by 18 ft. deep was dug in earth slightly more compact than "average." A Lambert cableway with towers 400 ft. apart was used, and it delivered the buckets to a chute that discharged into railroad cars alongside. The writer's record of cost was as follows:

	Per day.
30 men loading buckets, at \$1.50.....	\$45.00
1 signman (signaling engineman), at \$1.75	1.75
1 man hooking buckets to cable's trolley, at \$1.75	1.75
1 man dumping buckets, at \$1.75.....	1.75
4 men driving sheet plank and bracing, at \$1.50	6.00
5 men spreading earth in cars and moving cars, at \$1.50	7.50
1 engineman	3.00
1 fireman	1.75
1 waterboy	1.00
1 foreman	4.00
Total	\$73.50

The output was 260 buckets in 10 hrs., each bucket holding $1\frac{1}{4}$ cu. yds. of loose earth, which was probably not much more than 1 cu. yd. measured in cut. The wages and coal amounted to \$76 a day. Hence, not including the cost of timber sheeting, nor the hauling and unloading of cars, the cost of excavation was about 30 cts. per cu. yd. There was no backfilling, as the trench was for a retaining wall. When the bucket was traveling 360 ft. from pit to dump, the following time was required for each round trip:

	Seconds.
Raising bucket	15
Moving bucket 360 ft.....	35
Dumping bucket	25
Returning bucket	25
Lowering bucket	15
Changing buckets	15
Total	140

Almost 5 secs. could be saved on each of these six items if everything went well, but with the ordinary slight delays the above is a fair average for each round trip—that is $2\frac{1}{2}$ mins. A cableway may be used to advantage in pulling sheet planking, and one 2 x 10-in. plank buried 16 ft. in the earth can be pulled in 1 min., thus making the cost of timber removal merely nominal. In pulling the plank use a piece of 1 x 3-in. iron bent into a U-shape and with a ring welded to one leg of the U. It clings to the plank even though it is not held by a set screw or the like.

To move one of these cableways takes a gang of 15 men three days if they are "green" at the work, two days if they are used to it. The anchorage for the main cable is made by digging a trench 5 or 6 ft. deep and 16 ft. long, in which a log 16 or 18 ins. in diameter and 16 ft. long is laid, and the cable carried around its center. A short narrow trench leads off from the main trench so as to give a clear way for the cable to pass to the top of the tower. The main trench is filled with stones carefully laid over the log, and on top of the ground over the log is built a pile of stones 6 ft. high x 12 x 12 ft. To move all this rock for the anchors, to move the engine, towers, cables, etc., and set up again will seldom cost less than \$50, and frequently costs \$75, to say nothing of the lost time. If this cost is added to the cost of excavating the earth in a trench 370 ft. long, it will amount to several cents per cu. yd. Thus if the trench is only 6 ft. wide x 9 ft. deep, there will be 740 cu. yds. in 370 ft. of trench, and if it costs \$74 to move the cableway, we have 10 cents per cu. yd. of trenching chargeable to the cableway moving, besides the cost of excavation and backfill. For deeper and wider trenches this cost of moving, being distributed over a greater yardage, becomes a comparatively small item. Each case must be treated as a separate problem, in ascertaining the cost.

The following data have been obtained from The Carson Trench Machine Co., of Charlestown, Boston, Mass., makers of the Carson-Lidgerwood cableway much used on the Rapid Transit Subway New York City:

Two A-shaped bents or towers, 20 to 35 ft. high, and 200 to 300 ft. apart, support the $1\frac{1}{2}$ -in. cable along which the bucket travels. A hoisting engine at one end with two 7 x 10-in. cylinders and capable of lifting 5,000 lbs., raises and transports the buckets at a speed of 440 ft. a minute, or 5 miles an hour.

Aside from the men required to fill the buckets, the force required consists of an engineman, a fireman, a signalman, and a dumpman; and $\frac{1}{2}$ to $\frac{3}{4}$ -ton of coal is daily consumed. On a sewer in Orange, N. J., 44 buckets (1 cu. yd.) were handled per hour on an average, 80 being the maximum. The output depends upon the number of men digging, and the character of the material, but 250 cu. yds. a day may be taken as a good output.

The following costs are given in letters to the Carson Trench Machine Co.

Mr. Frank P. Davis, C. E., gives the following for a sewer in Washington, D. C.: Width of trench, 18 ft.; depth at which cableway began work, 15 ft.; distance of travel of 1 cu. yd. bucket, 150 ft.; number of trips per hour, 35; hours per day, 8; material, cemented gravel. Cost:

Engineman	\$ 3.00
Fireman	1.25
Signalman	1.00
2 dumpers, at \$1....	2.00
Coal, oil and waste.....	1.50
Interest and maintenance (estimated)....	7.00
	<hr/>
	\$14.75
30 men picking and shoveling.....	30.00
	<hr/>
Total for 280 cu. yds.....	\$44.75

Cost of picking, shovelling, hoisting 15 ft. and conveying 150 ft. to wagons, 16 cts. cu. yd. (Note that the wages were very low.) Bracing and sheeting was going on at the same time; the men did not know they were being timed.

James Pilkington, of New York, says: "I have excavated and refilled 250 cu. yds. in 10 hours at an expense of 15 cts. per yard. For rock excavation the cableway has no equal. I have taken the machine down and moved 250 ft., and put up, and was in working order in three hours and fifty minutes." This is unusually fast and indicates that Mr. Pilkington did not raise his towers by "main force and awkwardness."

Cost of Sewer Trench and Back Filling.—The city of Holyoke, Mass., built a system of sewers during 1908. The main sewers are 39 ins. and 54 ins. These are built of concrete blocks, there being 1,233 lin. ft. of them. The sewers were built by contract, but the excavation and backfilling was done by day labor, under the direction of the city engineer.

One trench was dug 14 ft. deep and about 4½ ft. wide, through sand and clay. The material was thrown on the side of the trench and used for backfilling. The following wages were paid for an 8-hr. day:

Foreman	\$3.50
Laborers	2.00

There were excavated from this trench 2½ cu. yds. per lin. ft. The cost per cu. yd. was \$1.21, giving a cost per lin. ft. of \$2.82.

The second trench was 14 ft. deep and about 6 ft. wide, the material being the same, mainly sand and clay. There were 3.11 cu. yds. of excavation per lin. ft. The cost of excavating and backfilling this trench was \$1.25 per cu. yd., making a cost per lin. ft. of \$3.90. All the excavation and backfilling was done by hand.

These high costs show how inefficient is the day laborer when working in the employ of a city instead of a contractor.

Cost of Excavating Trench With Orange Peel Bucket.—In *Engineering-Contracting*, April, 1906, a detailed description is given of the plant and methods used in building a large sewer in Chicago by city forces. For part of the work a 1 cu. yd. orange peel bucket was used. A traveling derrick, on rollers, was used. It was designed to swing in a full circle. The crew was:

	Per day.
1 engineman	\$ 4.80
1 fireman	2.50
1 signal man.....	3.25
1 powder man.....	3.25
2 laborers at \$3.25.....	6.50
Total per day.....	\$20.30

Under ordinary conditions, the orange-peel bucket excavated about 450 cu. yds. a day, all earth being dumped on a spoil bank at one side.

On the assumption that 450 cu. yds. were excavated per day, the labor cost was 4.5 cts. per cu. yd. About 50 lbs. of dynamite and $\frac{1}{4}$ ton of coal were used each eight-hour day. The cost of the dynamite was \$7.50 and the coal cost \$3 per ton, making the total cost for dynamite and coal \$9.75. The total cost per day for excavating thus was \$30.05; and the cost per cubic yard was 6.6 cts., exclusive of the wear and tear on the machine.

In this excavation the swinging derrick with the orange-peel bucket could be worked to better advantage than a steam shovel, inasmuch as it could work between the braces, which were 11 ft. centers. The bracing was placed as the excavation proceeded, and when the trench excavation was completed, the braces were all in place. By the use of the derrick the excavated material could be deposited far enough from the trench so as not to necessitate rehandling. In the case of a steam shovel it would have been necessary first to put in a temporary bracing, and a permanent bracing afterwards. Also, the boom of a steam shovel would not be long enough to deposit the excavated matter the necessary distance from the trench.

Cost of Sewer Trenching Using a Derrick.*—The trenching was done for a trunk sewer constructed at Big Rapids, Mich. The trench was 4 ft. wide and varied from 14 ft. 2 ins. to 17 ft. 3 ins. deep. A 15-in. pipe sewer was laid in the trench. A length of 1,000 ft. of sewer was constructed. The material was gravel and boulders. As much as 3 cords of stone in 400 ft. of trench were removed, many of the boulders required a 3,000-lb. chain fall to handle them. In addition most of the stone lay from 12 to 16 ft. deep, which made it very difficult to handle them between the braces. The gravel was treacherous and hard to hold, requiring two and sometimes three sections of sheeting and three and four stringers to hold it.

* *Engineering-Contracting*, Sept. 8, 1909.

The first 4 to 6 ft. of the trench was excavated by means of a slush scraper fitted with inside ears and ball so that it would cut vertical sides without the use of shovel or pick. A team and driver at \$2.75 per day did all this digging and also all filling. The gang employed and the wages per day were as follows:

Item.	Per day.
1 foreman at \$2.....	\$ 2 00
1 scraper team and driver at \$3.75.....	3 75
1 man holding scraper at \$1.50.....	1 50
1 man dumping scraper at \$1.50.....	1 50
2 men pulling sheeting and carrying it ahead at \$1.50.....	3 00
1 man setting top section of sheeting at \$1.50...	1 50
1 man tending derrick at \$1.50.....	1 50
1 horse and driver on haul line at \$2.50.....	2 50
4 men filling 2 buckets at \$1.50.....	6 00
1 man laying pipe at \$2.....	2 00
1 pipelayer's helper at \$1.50.....	1 50
Total	\$26.75

This gang completed from 46 to 54 ft. of sewer per day; this gives a labor cost of 58.2 cts. to 49.5 cts. per lin. ft. of sewer.

The derrick used on this work was a No. 1 Parker derrick made by the Parker Hoist & Machine Co., Chicago, Ill. Regarding the service of this derrick the contractor, Mr. D. J. Shafer, Big Rapids, Mich., says:

"In speaking of the derrick I can say that it reduced the cost of my ditch from 78 cts. per lin. ft. to 59 cts. per lin. ft. As soon as I put the derrick on the job I cut my crew from 26 and 28 men down to 16 men and dug more trench with much more ease than I did with the 28 men. The buckets held about 1/6 cu. yd. and with common work and 4 men filling buckets, 1 man dumping buckets, 1 man on the machine, with 1 man and horse, would handle 61 to 68 buckets of dirt every hour for 10 hours each day. In regard to moving the derrick, will say it never took us over 7 mins. to pull up stakes, move ahead 16 to 32 ft. and stake down and ready to lift dirt from the ditch. We moved the derrick two and three times a day."

Sizes and Prices of Sewer Pipe.—The manufacturers of vitrified sewer pipe east of the Illinois-Indiana line adopted, December 19, 1901, the standard weights and list prices given in Tables I, II and III. The western manufacturers use weights and list prices shown in Table IV.

On the Pacific Coast and in parts of the Northwest and Southwest some strictly local lists are used occasionally.

The standard length is 2 ft. for pipes up to and including 24-in. pipe. The standard length is 2½ ft. for 27-in. to 36-in. pipe. The size of the pipe is designated by its inside diameter. It will be noted that the list prices vary almost exactly with the weight of the pipe. Up to 18 diam. the Western price list follows closely the formula: List price = 0.4d³ + 15.

	6.00	30.00	30.00	30.00	5 1/2	365	81

Sizes 3-in. to 6-in., inclusive, in 2-ft. lengths.

Sizes 8-in. to 18-in., inclusive, in 2 1/2-ft. lengths.

Sizes 27-in. to 36-in., inclusive, in 3-ft. lengths.

*Both P Traps and Running Traps are made with or without hand inlet.

†Double Branches, both T and Y above 12-in. made only to order.

Branches, Increases, Decreases, Slants, 27 to 36-in. are 3 ft. long.

Large discounts from these prices are given. The present (August, 1909) discount for Eastern Pennsylvania is as follows:

Standard Pipe—	Per cent off.
3-in. to 24-in., Inc.....	79
27-in. and 30-in.....	71
33-in. and 36-in.....	66
Double Strength—	
15-in.	74
18-in.	72
20-in. to 24-in.....	72
27-in. and 30-in.....	63
33-in. and 36-in.....	58

No. 2 Pipe—

3-in. to 24-in., inc....	81
27-in. and 30-in.....	76
33-in. and 36-in.....	71

All pipe and branches in 2½ ft. or 3 ft. lengths to take 3 per cent less discount than above, except 27 in. and over.

Deep and Wide Sockets on Standard Pipe 4-in. to 24-in., inclusive, 2 per cent less than schedule discount. No extra charge is made for Deep and Wide Sockets on Double Strength Pipe 15-in. to 24-in. inclusive. Sizes 27-in. to 36-in., inclusive, are made only in Deep and Wide and no extra charge is made for same.

On First Quality Pipe, 1 per cent less discount than the above for allowing breakage and inspection at railroad point of delivery.

Freight allowed on car lots to points where the rate on Sewer Pipe from Akron, Ohio, is more than 14 cts and does not exceed 16 cts. per cwt.

Terms: 30 days or 2 per cent off net bills, after all deductions have been made, for cash in 15 days from date of shipment. Breakage (if any) in transit, at risk of purchaser. (Patton Clay Mfg. Co., Patton, Pa.)

Discounts from Western List, St. Louis, delivery (Evens & Howard Fire Brick Co., St. Louis), August, 1909, are:

Standard Pipe—	Per-cent.
3-in. to 6-in.....	77½
8-in. to 12-in.....	76
15-in. and 18-in....	70
20-in. to 24-in.....	65
27-in. to 30-in.....	62½
33-in. to 36 in..	60
Double Strength—	
13-in.	70
15-in. and 18-in.....	65
20-in. to 24-in.....	60
27-in. and 30-in.....	57½
33-in. to 36-in.....	55

Cement Required for Sewer Pipe Joints.—There are two kinds of sewer pipe: (1) The standard pipe with shallow joints; and (2) the special deep-socket pipe with wide and deep joints. The dimensions of these two kinds of joints are given in Tables II and III. Unless otherwise specified, the standard pipe with shallow joints is used; but many engineers prefer the deep-socket pipe, and specify it.

If the mortar is filled in the pipe joint and cut off vertically, flush with the face of the bell, the joint is called a "flush joint." If the mortar is also plastered on the outside, and beveled on a 1 to 1 slope from the outer edge of the bell to the body of the entering pipe, the joint is called an "overfilled joint" or a "beveled joint." The amount of mortar required for each of these kinds of joints is given in Tables V and VI. I have made no allowance for the space in the joint occupied by gasket or yarn. For discussion of the amount of cement per cubic yard of mortar see page 253.

TABLE V.—CEMENT REQUIRED TO LAY 100 FT. OF STANDARD SEWER PIPE.

	(2-ft. Lengths.)								
Size of pipe, ins....	4.	6.	8.	10.	12.	15.	18.	20.	24.

Overfilled joints..	.260	.400	.560	.680	.800	1.20	1.36	1.76	2.40
Bbls. cement (1 to 2 mortar):									
Flush joints.....	.105	.150	.180	.225	.270	.390	.435	.510	.780
Overfilled joints..	.195	.300	.420	.510	.600	.900	1.02	1.32	1.80

*The number of barrels of cement required to make 1 cu. yd. of mortar is given on page 253. I have assumed 4 bbls. per cu. yd. for 1 to 1 mortar, and 3 bbls. per cu. yd. for 1 to 2 mortar.

To calculate the cost of cement per lineal foot of pipe line multiply the fraction of a barrel of cement (given in Tables V and VI) by the prices of cement in dollars per barrel. Thus, if cement is \$2 per bbl., and the mortar is mixed 1 part cement to 1 part sand, and deep-socket pipe is to be used with overfilled joints, we find, from Table VI, that a 6-in. pipe requires 0.4 bbl. cement, multiplying this 0.4 by 2, gives 0.8 ct. per lin. ft. as the cost of cement, when cement is \$2 per bbl. Under these same conditions the cost of cement per lin. ft., for different sizes of pipe, is as follows:

Size of pipe, ins.	4	6	8	10	12	15	18	20	24
Cement, per ft., cts.....	0.5	0.8	1.1	1.4	1.6	2.4	2.7	3.5	4.8

Cost of Hauling Sewer Pipe.—The weight of sewer pipe is given in Table I, and if 2 tons (4,000 lbs.) are hauled per wagon load, a wagon will carry the following amounts of pipe at the costs given:

Size of pipe, ins....	4	6	8	10	12	15	18	20	24
Lin. ft. per wagon..	444	267	174	114	92	66	46	40	28
Cost of hauling, cts.									
per lin. ft., per mile	0.10	0.15	0.25	0.40	0.5	0.7	1.0	1.1	1.6

The cost of hauling is based upon wages of \$3.50 a day for team and driver, and 16 miles traveled per day. It is assumed that enough men are provided at both ends of the haul to load and unload the wagon rapidly enough to leave the team time to cover its 16 miles, or that extra wagons are provided for each team. The

cost of hauling 12-in. pipe, it will be seen, is $\frac{1}{2}$ -ct. per lin. ft. per mile. This does not include the cost of loading and unloading the pipe, which is practically as much more as the cost of hauling it one mile. Thus for 12-in. pipe, the cost of loading and unloading is $\frac{1}{2}$ -ct. per lin. ft., and to this must be added the cost of hauling at the rate of $\frac{1}{2}$ -ct. per lin. ft. per mile of distance from the freight yard to the sewer. In other words, to calculate the cost of loading and hauling pipe, determine the actual number of miles from the freight yard to the sewer and add 1 mile (to cover the cost of loading and unloading), then multiply by the cost of hauling given in the table. For example, if the actual haul is $1\frac{1}{2}$ miles, then, by the rule, add 1 mile, which makes $2\frac{1}{2}$ miles. If the pipe is 10-in. pipe, the table gives us 0.4 ct. per ft. per mile, which multiplied by the $2\frac{1}{2}$ miles gives 1 ct. per ft.

Cost of Laying Sewer Pipe. This will depend largely upon whether each pipe layer is provided with one or with two helpers to mix mortar and supply materials. As will be seen from cases subsequently given, two helpers to each pipe layer do not ordinarily increase the output sufficiently to justify the extra cost.

Pipe laid in a trench dug in rock, or in quicksand, usually costs twice as much for the labor of laying as in ordinary earth. When a pipe layer receives \$2.25 and his helper receives \$1.75 a day, the following costs per lineal foot are easily attainable under good management, and where no rock or quicksand are encountered:

Size of pipe, ins.....	4	6	8	10	12	18	20	24	30	36
Cts. per lin. ft.....	1	1 $\frac{3}{4}$	2	2 $\frac{1}{2}$	3	3 $\frac{1}{2}$	4	4 $\frac{1}{2}$	5	6

As will be seen from records given later on, the costs of pipe laying are frequently two or three times the above figures, but any contractor who finds his costs running higher than the above, had better investigate his management. By giving the men a bonus for every foot laid in excess of a given number of feet laid each day the costs of pipe laying may be reduced considerably below the above given figures. Of course the cost of trenching and backfilling is not included in the above costs.

Diagram Giving Contract Prices of Sewers.—The diagram, Fig. 2, is one that I have prepared from data given by Mr. G. M. Warren, based upon contract prices for about 60 miles of sewer work in Newton, Mass., and covering a period of four years, 1891-1895. The wages of common laborers were \$1.50 for 10 hrs.

The prices for trenching include excavating, sheeting and backfilling in earth; and do not relate to work in rock or quicksand.

The price of 1 ct. per inch of diameter of pipe per lin. ft. laid, includes hauling of pipe, labor of laying, and cement for joints.

The price of pipe is 70% off the list price given in Table I, plus 20% to cover the cost of branches which are placed 25 ft. apart. For example, the list price of 12-in. pipe is \$1.00; and with 70% discount the price becomes 30 cts. Now, 20% of 30 cts. is 6 cts., which approximately covers the extra cost of branches spaced 25 ft. apart, so that the total cost of the pipe for a 12-in. pipe line is 30 cts. plus 6 cts., or 36 cts. To this is added 12 cts. (1 ct. for

Fig. 2. Contract Prices of Pipe Sewers.

each 12 ins. of diameter) to cover the price of "laying," making a total of 48 cts., exclusive of trenching. The first 8 ft. in depth of trench are dug at a price of 50 cts. per cu. yd. The next 8 ft. below are dug at a price of 50 cts. per cu. yd., and the price for each succeeding 8-ft. lift is 25 cts. higher per cu. yd. than the preceding lift. This is based upon the assumption that trench machines are not used, and that the earth is raised in 8-ft. lifts.

To show how to use the diagram, an example will serve. Suppose it is desired to know the contract price for a 12-in. sewer in a trench 16 ft. deep. Start at the bottom of the diagram on the line marked 15, and follow the line up until it meets the sloping line marked 18". Then starting from this intersection, follow the straight line across the page to the right until the side of the diagram is reached, when it will be seen that the intersection is just one division above \$1.50; and, as each division is equal to 5 cts., the price is \$1.55 for a 12-in. pipe in a 16-ft. trench. This price includes contractor's profits.

Cost of Pipe Sewers at Atlantic, Ia.—In *Engineering-Contracting*, May 15, 1907, appeared the first of a series of articles on the cost of pipe sewers, the data for which were gathered by Mr. M. A. Hall, the engineer in charge of the work. Mr. Hall had the inspectors report daily the organization of the forces working under the various contractors, and the amount of work accomplished. With the exception of the item of cement used in filling the pipe joints, it is believed that these records of cost are very reliable. The first of this series of articles related to sewer work at Atlantic, Iowa. The data, as originally published in *Engineering-Contracting*, were so voluminous that I have made a great condensation, but I believe that, in the condensed form here given, the costs are more available for use, and that nothing of great importance has been omitted.

The excavation was, for the most part, a clay not difficult to spade, and requiring little or no bracing and practically no pumping. The "bottom men" shoveled the earth out of the trench and the "top men" shoveled as much of it back from the edge as was necessary. The backfilling was done, for the most part, by a team and drag scraper, and there was no ramming.

Table VII gives the costs at Atlantic, Ia. To the labor costs, Mr. Hall thinks 10% should be added for overhead charges and incidentals, to cover office expenses, hauling tools, moving materials from place to place so as to use up odds and ends, etc.

The contractor was his own foreman and handled his men well. The weather was good, the work being done between April and October, 1904. A 10-hr day was worked. Natural cement (Louisville) was used.

It will be noted that the excavation for the 30-in. sewer cost less not only per lin. ft. but per cu. yd. than for any of the others. This is due largely to the fact that the trench was shallow, also to the fact that the earth was a heavy, black soil, very easily spaded.

On a short job of 16-in. sewer, 360 ft. long, where the trench was 24 ins. wide and 12 1/2 ft. deep, in clay that was good spading, the cost was as follows for excavation:

	Per lin. ft.
Bottom men	\$0.299
Top men	0.104
Scaffold men	0.045
Bracing men	0.005
Total	\$0.453

This is equivalent to 34.8 cts. per cu. yd.

The backfilling cost 2.8 cts. per cu. yd. additional.

The costs in Table VII are averages of several jobs. The minimum costs of pipe laying on the best of these jobs were as follows per lineal foot:

	8-in.	10-in.	12-in.	15-in.
Pipe layers, at 22½ cts.	\$0.009	\$0.008	\$0.011	\$0.015
Helpers, at 17½ cts.	0.007	0.007	0.008	0.009
Total	\$0.016	\$0.013	\$0.019	\$0.024

By dividing the pipe layers' hourly wage (22½ cts.) by the costs per lineal foot, we find the total number of feet laid per hour per pipe layer; thus, $22\frac{1}{2} \div 0.9 = 25$ ft. of 8-in. pipe laid per hr. per pipe layer, or 250 ft. per 10-hr. day. In this manner the following table was calculated:

8-in. pipe, 250 ft. per day per pipe layer
10-in. pipe, 375 ft. per day per pipe layer
12-in. pipe, 205 ft. per day per pipe layer
15-in. pipe, 150 ft. per day per pipe layer

It will be noted that the 10-in. pipe was laid with abnormal rapidity in this particular case. On another job, 10-in. pipe was laid at the rate of 250 ft. per day.

TABLE VII.—COST OF PIPE SEWERS, ATLANTIC, IOWA.

Cost of Pipe Sewers at Centerville, Iowa.—In *Engineering-Contracting*, June 12, Aug. 21, Sept. 18 and Oct. 16, 1907, voluminous tables were published giving the cost of pipe sewers at Centerville, Iowa, the data for which were gathered by Mr. M. A. Hall. The work was done by contract on 161 different jobs, covering more than ten miles of sewer. The average cost of pipe laying, not including trenching, was as follows:

8-in. pipe, 5.0 cts. per lin. ft. (average of 83 jobs).
10-in. pipe, 7.3 cts. per lin. ft. (average of 27 jobs).
12-in. pipe, 7.5 cts. per lin. ft. (average of 41 jobs).
15-in. pipe, 6.7 cts. per lin. ft. (average of 10 jobs).

Apparently none of this work was as well handled as that at Atlantic, Iowa, the data for which have been previously given. Average costs on work so simple as pipe laying, and where no plant is required, often indicate nothing but poor management or laziness. For this reason the following minimum costs of work done at Centerville are of more value, as they show what can readily be accomplished:

	8-in.	10-in.	12-in.	15-in.
Pipe layers, at 30 cts.	\$0.010	\$0.017	\$0.019	\$0.016
Helpers, at 17½ cts.	0.012	0.018	0.011	0.020
Total	\$0.022	\$0.035	\$0.030	\$0.036

Even these minimum costs at Centerville are greater than the average costs of pipe laying given above for the work at Atlantic, Iowa. At Atlantic the contractor usually had only one helper to each pipe layer, whereas on this work at Centerville there were usually two helpers to each pipe layer. The wages of the pipe layers at Centerville were nearly 40% higher than at Atlantic, but the helpers received the same wages in both places.

Based upon the above table of minimum cost, the following is the number of lineal feet laid per 10-hr. day by a pipe layer:

8-in. pipe, 300 lin. ft. per pipe layer.
10-in. pipe, 177 lin. ft. per pipe layer.
12-in. pipe, 158 lin. ft. per pipe layer.
15-in. pipe, 188 lin. ft. per pipe layer.

A considerable part (15%) of the work done at Centerville involved trenching in hardpan and hard shale, and there was a little quicksand and some wet weather that caused the banks to cave. All these increased not only the cost of excavating, but also the cost of pipe laying. On the various jobs where the excavation was entirely in shale and hardpan, the cost of laying was 50% more than the average costs above given; so that for 10 and 12-in. pipe the cost of pipe laying was about 11 cts. per lin. ft.

Where quicksand, or a trench soaked from rain, was encountered the cost of pipe laying was similarly increased, that is about 50% above the average cost.

The trenching averaged a cost of 40 cts. per cu. yd. for excavation and 4 cts. per cu. yd. for backfilling, except in shale and hardpan, where the cost was about 70 cts. per cu. yd. for excavation. About 15% of the excavation was shale that could be picked and hardpan. The rest was mostly clay and gumbo, requiring prac-

tically no sheeting. The trenches averaged about 9 ft. deep. The width of the trenches was the same as at Atlantic, above given. Wages averaged 18 cts. per hr. It will be noted that the trenching at Centerville cost practically twice as much per cubic yard as at Atlantic. In view of the fact that the pipe laying also cost twice as much, it would seem that the workmen at Centerville were about half as efficient as those under the contractor at Atlantic.

Foreman's and waterboy's wages are not included in the above given costs for labor of trenching and pipe laying. Foreman received 35 cts. per hr., and waterboys 12½ cts. per hr. Their combined wages amounted to about 10% of the labor cost of trenching, backfilling and pipe laying. This shows that there were one foreman and one waterboy to 25 workmen.

Cost of Pipe Sewers at Laurel, Miss.—In *Engineering-Contracting*, July 24, 1907, the cost of 3 miles of pipe sewers on each of 43 sections was given. The data were secured by Mr. M. A. Hall in the manner previously described under the paragraph relating to sewer work at Atlantic, Iowa.

Negroes were employed and the work was done under inefficient foremen, except on 8 of the sections. The working day was 10 to 11 hrs. long. Common laborers received \$1.25 to \$1.50 a day, and foremen received \$3 to \$4 per day.

The excavation was mostly clay, and the average cost of excavation was 30½ cts. per cu. yd., wages being assumed to average 12½ cts. per hr. The backfill was largely done by hand, although teams and scrapers were used on many of the sections. The backfill averaged about 6 cts. per cu. yd. The following were the costs on a few of the sections that showed the lowest costs:

	Per cu. yd.
Excavation of trench 6.3 ft. deep, 1.62 hrs., at 12½ cts.	20.2
Backfill ditto, 0.3 hr. man at 12½ cts. plus 0.06 hr. team and driver at 30 cts.	5.6
Excav. of trench 7.6 ft. deep, 1.80 hrs., at 12½ cts.	22.5
Backfill ditto, 0.24 hr. man, at 12½ cts., plus 0.04 team and driver, at 30 cts.	7.2
Excav. of trench 7.7 ft. deep, 2.07 hrs., at 12½ cts.	26.0
Backfill ditto, 0.12 hr. man, at 12½ cts., plus 0.03 hr. team, and driver, at 30 cts.	2.4

The average costs of pipe laying were as follows per lin. ft., wages being assumed to be 20 cts. for pipe layers and 12½ cts. for helpers:

	8-in.	10-in.	12-in.	18-in.	20-in.
Pipe layer, at 20 cts.	\$0.010	\$0.012	\$0.011	\$0.015	\$0.012
Helper, at 12½ cts.	0.013	0.012	0.018	0.026	0.023
Total	\$0.023	\$0.024	\$0.029	\$0.041	\$0.034
Number of sections	31	3	2	5	2

There were, ordinarily, two helpers to each pipe layer.

For comparison with the above averages, the following minimum costs of pipe laying on certain sections are given:

	8-in.	10-in.	12-in.	18-in.	20-in.
Pipelayer, at 20 cts.	\$0.005	\$0.010	\$0.009	\$0.008	\$0.012
Helper, at 12½ cts.	0.008	0.012	0.015	0.018	0.022
Total	\$0.013	\$0.022	\$0.024	\$0.026	\$0.034

That these minimum costs vary so slightly from the average costs on sections other than for the 8-in. pipe is due to the fact that there were so few sections where sizes larger than 8-in. were laid.

Estimated Cost of Pipe Sewers. — In *Engineering-Contracting*, April 1, 1908, the Table VII A was published. The estimated costs given in this table are said to be based upon the actual costs of 51 miles of sewers built in five cities where the physical conditions were similar to those at Clinton, Iowa, as compiled by Mr. Charles P. Chase, city engineer of Clinton. The table gives the estimated cost per lin. ft., not including the cost of excavation, nor foremanship and incidentals.

I have omitted the item of "foreman" from the above table. Foreman's salary usually amounts to 5 to 10% of the labor—not 3 to 10% of the labor and materials.

I have also omitted an item of "Interest and Incidentals," which Mr. Chase estimates at 10% of the total cost of labor and materials. Interest on money invested is a very small item where the contractor receives monthly payments, and a percentage for "Incidentals" should apply only to the labor.

Mr Chase calls the total of the above items a "constant," and to this "constant" he adds the cost of trenching, which is the "variable."

There is an error in the item of laying 36-in. pipe, as will be seen by comparison with the corresponding item for 30-in. pipe. The item of "shipping loss and haul" appears to be much overestimated; so also is the item of "lights and watchman."

Cost of a Pipe Sewer in Quicksand.—The following data were published in *Engineering-Contracting*, June 3, 1908.

Wildwood is a new summer resort town, built a few years ago on the southern end of an island called Five Mile Beach, on the New Jersey coast. Prior to the building of the town the site was covered at high tide by 3 ft. of water. The soil was black mud covered with thick meadow sod, with, here and there, piles of sand which were shifted by the tide. The first work done was to build a bulkhead and by means of dredges to raise the land above the high tide. Then the building of the town and resorts began.

To serve the buildings, a system of terra cotta pipe sewers was built. The trench for the entire distance, 12 miles, was through quicksand, from which water bubbled, and known locally as "boiling sand." This makes both expensive and difficult work, adding to the cost of laying the pipe, as it is difficult to keep the pipes at the proper grade and in good alignment, and the joints are hard to caulk, owing to the water in the ditch.

The greatest cutting was 6½ ft. deep and the entire trench was double sheeted throughout, great trouble being experienced in keeping the trench even partially dry. Sumps or wells could not be made, as the pumps pulled out so much sand under the sheeting as to cause either the ditch to fill or the sheeting to cave in.

The sheeting was put down to a depth of 10 ft. with a water jet in advance of the excavation, this being the only way the contractor could make any headway. Owing to the numerous "salt

TABLE VII A.—Cost of PIPES SEWERS.

holes" encountered, through which the line at time ran, it was necessary to make a foundation for the manholes and pipe. This was done by piling spaced 7 ft. apart and 6 in. c. to c. On the piles 4 x 4 yellow pine, 8 ft. long, was spiked, and to this was spiked hemlock planks 2 x 8—12 ft. long. The pipe was laid on this and the hole filled with sand and salt hay.

If a manhole was located at one of these "salt holes," 4 piles, 10 to 15 ft. long were driven $4\frac{1}{2}$ ft. c. to c. Four railroad ties were then spiked together with two pieces of batten, and the whole bolted securely to the piles. On this foundation was placed a box 5 ft. square and 10 ins. deep, the bottom being covered with tongue and grooved floor boards, and in some cases lined with canvas and the inside covered with coal tar pitch. The concrete was placed in the box, the pipe line run through, and the brick work completed.

As a general rule, water was struck in excavating the trench about 18 ins. below the surface. The pipe laid was 8 and 12 in.

Fig. 3.—(1) Centrifugal Pump; (2) Boiler; (3) Piston Pump; (4) Pipe in Trench; (5) Trench Being Excavated; (6) Suction Pipe; (7) Discharge Pipe; (8) and (9) Steam Pipes; (10) Pipe to Water Supply.

terra cotta, hence the ditch was made only wide enough for a man to work in it easily, this width being 2 ft. for a ditch 6 to 7 ft. in depth.

The method of excavating was as follows: By using the piston pump the shenthing was put down for a distance of 150 ft. along the trench, and a closure made at each end. Then 10 laborers were put in the trench and excavation made to the water line, when rangers and braces were set.

The piston pump was then started pumping water into this "land coffer dam." A centrifugal pump was moved into position, and the discharge pipe placed midway in the last section, where the sewer pipe had already been laid. Thus the centrifugal pump excavated the material from the forward section and backfilled the last section at the same time. See Fig. 3.

When grade was reached, the foundation piles were jettied down and the cradle constructed. The pipe was then laid, the joints being made with cement and tar. The next section was then done in the same manner.

The sand excavated was quite coarse, and but little agitation was necessary with shovels, in order to allow the pump to pick up the sand. When the sand is fine grained, much more water is needed,

and likewise the sand must be agitated with shovels. With extremely fine sand, the men must be relieved frequently, as the work is hard, and, as the pumps take up a much smaller percentage of the sand, the ditch must be kept with a larger amount of water in it, and the men, being compelled to stand in the water, feel the effect of it quickly.

At times when the contractor got as deep in the trench as the original ground surface, he encountered a considerable number of roots that had to be cut out, but this was seldom necessary.

Fig. 3 shows the layout of the plant to do the work in the manner described. In this way an average of 300 lin. ft. of trench was dug and pipe laid per day, while another contractor doing similar work by another method averaged only from 35 to 50 ft. per day.

The cost of driving the sheeting and pulling it for the 300 lin. ft. of trench done per day was:

Boss timberman	\$ 2.50
Fireman on jet pump.....	1.50
One man setting sheeting.....	2.00
Two helpers, at \$1.50.....	3.00
Three men pulling sheeting, at \$1.50.....	4.50
One man carrying sheeting.....	1.50
Two men bracing trench, at \$2.00.....	4.00
One man pumping	1.75
Coal and oil	1.00
Total	\$21.75

This gives a cost per lin. ft. of trench of 7 cts. for driving and pulling sheeting, and as there was 6,080 lin. ft. of sheeting driven and pulled a day, it makes a cost per lin. ft. of sheeting $\frac{1}{2}$ -ct. With 2-in. sheeting used, the amount of timber was 6,000 ft. B. M., which cost \$26 per M. This timber, being driven with a water jet, was used time and time again. The sound piles, which were from 10 to 15 ft. long, cost 25 cts. apiece, and the cost of driving them was 1.5 cts. per lin. ft.

The cradle for the pipe was built by two men, each at \$2 per day. They built 200 lin. ft. per day, which meant a cost per ft. of trench of 2 cts. The amount of lumber in 200 ft. of cradle was 966 ft. B. M., which meant a labor cost for framing of about \$5 per M. The lumber cost \$26 per M.

The daily cost of digging the trench and backfilling, and of laying the pipe was:

Foreman, 10 hrs.....	\$ 4.00
Eight men digging, at \$1.50.....	12.00
Two men trimming, at \$1.50.....	3.00
One engineman	3.00
One pumper	2.50
Two pipemen, at \$2.00.....	4.00
Coal, at \$5.00 per ton.....	1.25
Rent of boiler.....	2.00
Rent of pumps.....	2.50
Rent of engine.....	2.00
Two pipelayers, at \$2.00.....	4.00
Two pipe carriers, at \$1.50.....	3.00
One man on mortar and jute.....	1.50
Total	\$44.75

The excavation and backfilling done by the pumper can be listed as follows:

Cost per lin. ft. of trench	
Labor	\$0.032
Coal	0.004
Plant rental .. .	0.022
Total	\$0.058

Each day this plant excavated about 200 cu. yds., hence the cost per cu. yd. was:

Labor	\$0.047
Coal	0.006
Plant rental	0.032
Total .. .	\$0.085

This is a very low cost for excavating earth from a trench and backfilling it.

The terra cotta pipe cost 16 cts. per lin. ft. and the hauling of it cost 2 cts.

The total cost per lin. ft. of pipe laid was as follows, exclusive of manholes:

Foreman	\$0.013
Excavating and backfilling by hand .. .	0.050
Excavating and backfilling by pump:	
Labor	\$0.032
Coal	0.004
Plant rental	0.022
Driving sheeting	0.038
Bracing trench	0.040
Pulling and carrying sheeting	0.013
Piles in place	0.020
Piles in place	0.105
Cradle, lumber and labor	0.132
Pipe	0.160
Hauling pipe	0.020
Laying pipe	0.028
Materials for joints	0.013
Total	\$0.652

This cost does not include any allowance for general expense nor for the materials used in shoring the sides of the trenches. The sheeting was used many times, as driving the planks with a water jet did not injure the planks or break them up.

The cost of a manhole was as follows:

Cover and frame	\$ 9.00
Bricklayer	2.00
Bricks, 1,500, at \$10 per M.	15.00
Stone, $\frac{1}{4}$ cu. yd., at \$1.0075
Cement, 3 bags, at 50 cts.	1.50
Pumping	1.12
Labor, excavating	3.18
Sheeting, etc.	2.17
Total	\$34.72

The cost of this work in a ground difficult to excavate is exceedingly low, and can be attributed to the methods used in carrying on the work.

Mr. George L. Watson, M. Can. Soc. C. E., was chief engineer of the Wildwood Sewer Co., and designed the entire improvement made, including the sewers. He afterwards associated himself with the

contractor for the sewers, Mr. Alexander Murdock; and, as engineer in charge, decided upon and put into operation the method used.

Cost of Two Pipe Sewers and Manholes at Oskaloosa, Ia.*—The following cost data relate to the construction of a 12-in. sanitary sewer in Sixth avenue, and an 8-in. sewer in South Market street, Oskaloosa, Ia.

The Sixth avenue sewer consisted of 1,004 lin. ft. of 12-in. pipe (tile), five manholes and one lamp hole. The work required the excavation of 1,063.8 cu. yds. of material, the average depth being 11.4 ft. and the maximum depth 16 ft. On this sewer there were about 250 ft. of trench in which the depth was from 13 to 15 ft. This necessitated handling part of the earth three times before it was removed from the trench, which added considerably to the cost of excavation. The cost of the 1,004 lin. ft. of 12-in. sewer was as follows:

<i>Cost of 12-in. Sewer.</i>		Per lin. ft.
	Total.	Sewer.
Labor:		
Trenching	\$ 543.90	\$0.541
Sheeting	72.00	.073
Laying pipe	46.33	.046
Backfilling	93.65	.093
Miscellaneous expense, laying pavement, hauling, etc.....	46.00	.045
Total, labor	\$ 800.93	\$0.797
Materials.		
Lumber for sheeting.....	\$ 32.30	\$0.032
Cement for joints, 15 sacks....	5.40	.005
Sand for joints, 30 bu.....	1.80	.002
Jute calking, 50 lbs.....	3.50	.003
Pipe, 958 lin. ft.....	249.08	.248
Specials, 14, at \$0.72.....	10.08	.010
Total, materials	\$ 302.16	\$0.301
One lamp hole, 13 ft. deep....	4.20	.004
Five manholes	274.82	.274
Grand total	\$1,382.11	\$1.377

In the above work there was 980 lin. ft. of trenching, the cost per lin. ft. being \$0.555. The cost of sheeting the 980 lin. ft. of trench was:

	Total.	Per lin. ft.
	Trench.	
Labor	\$ 72.00	\$0.073
Lumber	32.30	.033
Total	\$104.30	\$0.106

There were 400 joints, requiring 15 sacks of cement and 30 bushels of sand, the cost per joint being \$0.018. The calking for the 400 joints took 50 lbs. of jute, or .125 lb. per joint, and cost \$0.009 per joint.

The South Market street sewer consisted of 816.8 lin. ft. of 8-in. tile, two manholes and one lamp hole. There were 865.9 cu. yds.

**Engineering-Contracting*, Sept. 22, 1903.

of excavation, the average depth being 6.6 ft., and the maximum depth 10.6 ft. The cost of this sewer was as follows:

Cost of 8-in. Sewer.

	Total.	Per lin ft. Sewer.
Trenching	\$113.40	\$0.139
Sheeting trench and miscellaneous	15.00	.018
Laying pipe	21.35	.026
Backfilling	15.25	.019
Cement for joints, 6 sacks.....	2.16	.002
Sand for joints, 20 bu.....	1.20	.001
Pipe, 780 lin. ft.....	121.60	.149
Specials, 13, at \$0.72.....	12.96	.016
Total	\$302.90	\$0.369
One lamp hole, 10 ft. deep.....	4.30	.005
Two manholes	64.89	.081
Grand total	\$372.09	\$0.455

There was 805.6 lin. ft. of trenching, the cost per lin. ft. being \$0.14. There were 327 joints, requiring six sacks of cement and 20 bushels of sand, the cost per joint being \$0.011.

In the above work the cost of laying tile includes taking out the last spading from the bottom of the trench, and tamping same about tile previously laid. Each tile was laid to line and grade from a grade cord supported over trench, the supports consisting of two upright 2 x 4 pieces, and cross board, spaced 25 ft. apart. Joints were calked and cemented, bevel pattern, with 1:1 Portland cement mortar.

The backfilling was done with team and scraper and two men. Earth was first put in the trench to within about 1 ft. of the top, and the trench then flooded with the fire hose. The balance of the earth was then scraped onto the trench. This has proven a very satisfactory method, as practically all of the earth goes back into the trench in a short time.

The soil consists of from 1 to 3 ft. of black loam on the surface, under which is tough clay. As the ground this summer contained very little water, only skeleton bracing was used.

Prices and Wages.

The prices of materials delivered on the work were as follows:

Cast-iron manhole and lamp hole covers, \$0.025 per lb.

Wrought-iron manhole steps, \$0.24 each.

No. 1 vitrified paving brick, \$11.00 per M.

Cement, \$0.36 per sack.

Sand, \$0.06 per bu., 100 lbs. per bu.

Jute calking, \$0.07 per lb.

8-in. tile, \$0.156 per lin. ft.

10-in. tile, \$0.26 per lin. ft.

Oak lumber, \$38.50 per M.

The wages paid were as follows:

Brick masons, \$0.55 per hour for 8 hours.

Tile layer, \$2.50 per day.

Common labor, \$0.20 per hour for 9 hours.

Team and driver for backfilling, \$0.40 per hour.

Cost of Manholes.

The manholes were built of No. 1 vitrified paving brick on a foundation of 1:4:8 concrete from 8 in. to 1 ft. thick under the walls. Portland cement mortar mixed 1:2 was used in building walls, all joints being slushed full. The walls were 12 in. thick at depths greater than about 12 ft. and 9 in. thick above this depth.

Below is given cost of two manholes of different depths:

Manhole 16.5 ft. deep, requiring 20.4 cu. yds. excavation.

Excavation:

Labor, at \$0.20 per hour.....\$ 9.40

Foundation:

Labor, at \$0.20 per hour..... 2.40

2 sacks cement, at \$0.36 per sack..... 1.08

0.4 cu. yd. sand, at \$1.40 per yd..... 0.56

1 cu. yd. crushed brick, at \$2.30 per cu. yd.. 2.30

Superstructure Manhole:

2,400 brick, at \$11.00 per M..... 26.40

16 sacks cement, at \$0.36 per sack..... 5.76

26 bu. sand, at \$0.06 per bu..... 1.56

1 C. I. cover, 307 lbs., at \$0.025 per lb.... 7.68

1 dust pan, 50 lbs., at \$0.025 per lb..... 1.25

8 steps, at \$0.24 each..... 1.92

2 pieces split tile in bottom..... 0.65

Brick mason, 10 hrs., at \$0.55 per hr..... 5.50

Hod carriers, at \$0.20 per hr..... 6.00

Total cost of manhole.....\$72.46

Manhole 8.4 ft. deep, requiring 8.2 cu. yds. excavation.

Excavation:

1 man 13 hrs., at \$0.20 per hr.....\$ 2.60

Foundation:

Labor, at \$0.20 per hr..... 0.80

2 sacks cement, at \$0.36 per sack..... 0.72

.25 cu. yd. sand, at \$1.40 per cu. yd..... 0.35

.5 cu. yd. crushed brick, at \$2.30 per cu. yd. 1.15

Superstructure Manhole:

1,100 brick, at \$11.00 per M..... 12.10

6 sacks cement, at \$0.36 per sack..... 2.16

10 bu. sand, at \$0.06 per bu..... 0.60

1 C. I. cover, 307 ft., at \$0.025 per lb.... 7.68

1 dust pan, 50 lbs., at \$0.025 per lb..... 1.25

3 steps, at \$0.24 each..... 0.72

2 pieces split tile in bottom..... 0.40

Brick mason, 8 hrs., at \$0.55 per hr..... 4.40

Hod carriers, at \$0.20 per hr..... 1.60

Total cost of manhole.....\$26.52

All of the above work was done this summer by lay labor under the supervision of Mr. E. F. Bridges, City Engineer, to whom we are indebted for the information from which this article was prepared.

Cost of Two Pipe Sewers.*—The following costs relate to two small jobs of 8-in. pipe sewer constructed during 1908 at Fredericton, N. B. The work was done by day labor and the wages paid were:

	Cents.
Foreman, per hour.....	30
Laborers, per hour.....	18
Single team, per hour.....	25
Double team, per hour.....	50

A 9-hour day was worked. The 8-in. terra cotta pipe cost 22½ cts. per foot, and Gillingham cement cost \$2.10 per barrel delivered on the work. Lumber for studding cost \$16.50 per 1,000 ft. B. M. The manholes were elliptical 4 ft. x 3 ft. in diameter with 8-in. brick walls and 12-in. tube.

Waterloo Road Sewer.—This job comprised 495 ft. of 8-in. pipe sewer with 2 manholes. The average depth of trench was 9.7 ft. It cost as follows:

Item.	Total.	Per unit.
5.98 cu. yds. brick work.....	\$ 83.10	\$13.85
533.5 cu. yds. excavation.....	274.97	0.515
Laying 8-in. pipe (495 lin. ft.).....	20.73	0.04

The cost of the sewer, including sheeting, which is lumped with excavation in the above costs, was \$0.93 per lin. ft. The trench had to be close sheeted every foot of its length, the material being sand and the bottom 4 ft. wide.

Phoenix Square Sewer.—This job comprised 811 ft. of 8-in. pipe sewer, with 3 manholes. The average depth of trench was 5.3 ft. in sand and loam, which had to be braced about every 4 to 6 ft. The trench was dry. The cost of the work was as follows:

Item.	Total.	Per unit.
4.32 cu. yds. brick work.....	\$ 54.00	\$12.50
522.5 cu. yds. excavation.....	195.30	0.374
Pipe laying (811 ft.).....	37.70	0.034

The total cost of the sewer was \$425.15 or \$0.52 per lin. ft.

We are indebted for the above information to A. K. Grimmer, city engineer, Fredericton, N. B.

Cost of 8-in. to 18-in. Sewers at Cardale, Ga.—In *Engineering News*, March 30, 1893, Mr. Geo. G. Earl, C. E., gives the cost of some pipe sewer work at Cardale, Ga. Wages were 80 cts. to \$1 per day for labor (presumably negroes) and the foreman received \$70 a month.

**Engineering-Contracting*, Aug. 25, 1909.

Size of pipe.	Depth of trench in ft.	Length in ft.	Cost of labor, cts. per ft.	Cost of foreman, cts. per ft.
8 inches	7.5	1,135	14.1	1.0
8 inches	7.5	1,135	22.8	1.9
9 inches	8.0	79	32.8	1.8
9 inches	8.0	425	35.2	5.5
10 inches	9.0	1,135	26.7	1.1
10 inches	1.0	256	35.5	1.6
12 inches	1.4	1,044	27.0	1.1
12 inches	6.0	967	32.5	1.7
15 inches	10.6	867	19.2	1.0

The "Cost of Labor" given in the fourth column includes trenching, pipe laying and backfilling.

In building 2.6 miles of sewer (2 miles of which were 8-in.) and 25 manholes, the total cost was:

Labor	\$2,867
Masons and helpers	462
Sundries	17
Foreman	266
Supervision	1,000
Pipe	2,635
Brick	252
Cement	166
Hauling	83
Manhole covers	229
Tools and incidentals	561
Total	\$9,596

It will be noted that the foreman's wages amounted to about 6% of the total wages paid to laborers and masons.

Cost of a 12-in. Pipe Sewer, Menasha, Wis.—In 1903, some pipe sewers were built in Menasha, Wis., by day labor. I am indebted to Mr. S. S. Little for the following data: There were 2,200 ft. of trench, about half of which was for 12-in. pipe and half for 15-in. pipe. The depth of trench ranged from 7½ to 10 ft., averaging 9 ft., and the width was 2 ft. The material was solid red clay. Wages paid were \$1.75 per 10-hr. day. Some team work, at \$3.50 a day, was used in scraping in the backfill. The labor of trenching, laying pipe, and backfilling averaged 37 cts. per lin. ft. of trench. If the pipe laying cost 4 cts. per ft., the cost of trenching and backfilling was 33 cts. per ft., or 60 cts. per cu. yd.

Cost of 8-in. Sewer at Ithaca, N. Y.—In *Engineering News*, Aug. 20, 1896, Mr. H. N. Ogden, C. E., gives the following costs of trenching and laying 8-in. sewer pipe in Ithaca, N. Y. The column of labor cost is based on daily wages of \$1.85 for laborers, \$1.50 for pipe layers, and \$2 for foreman. Mr. Ogden has kindly informed the writer that the working day was 10 hours long. Teams were paid \$2.50, masons on manholes, \$3.50, and masons' helpers, \$1.50; 8-in. sewer pipe cost 12½ cts. per ft. Natural cement, at 95 cts. per bbl., laid 120 to 243 ft. of pipe per bbl. (Doubtless neat cement mortar was used.) The work was by contract, and not all under

the same foreman; hence the variation in cost shown in the table.

Name of street.	Length laid.	Depth of trench in ft.	Material.	No. of day's work.	—Cost of labor.—	
					Total.	Per ft.
Wheat	1,134	5.3	1	4	\$126.50	\$0.11
Corn	1,504	5.8	2	5	200.70	.12
Washington	398	4.9	3	1½	49.50	.12
Titus	1,391	6.8	4	4½	318.90	.23
Plain	1,332	5.9	5	7	209.00	.16
Buffalo	597	6.7	6	4	108.25	.18
Fayette	984	5.6	7	4	195.05	.20
Centre	1,334	6.8	8	7	847.00	.26
Green	1,919	5.7	9	11	418.85	.22
Clinton	2,403	5.4	10	11	519.85	.22
Albany	1,431	5.0	11	9	319.50	.22
Geneva	1,323	5.3	12	7	373.47	.28
Cayuga	1,413	6.3	13	10	468.25	.33

¹ Wet clay; water 3 ft. down, bailed out.

² Wet clay; water 3 ft. down, bailed out, occasional bracing.

³ Wet clay.

⁴ Loam over wet clay; water 6 ft. down; occasional bracing.

⁵ Wet clay; water 5 ft. down; diaphragm pump, occasional bracing.

⁶ Clay and gravel; much water in places; pump; braced.

⁷ Wet clay; water 4 ft. down, occasional bracing and pumping.

⁸ Wet clay; water 3 ft. down, 1 diaphragm, occasional bracing.

⁹ Half clay, half gravel; half close sheeted; underdrain pumps.

¹⁰ Wet clay, some gravel pockets; 1 pump; some bracing.

¹¹ Gravel containing water at 5 ft.; pump, half sheeted.

¹² Sheet piling and pumping entire; water at 5 ft.

¹³ Loose gravel; brick pavement removed; half braced and half sheeted.

Cost of 12-in. Sewers in Toronto, Canada.—A large number of 12-in. pipe sewers were built by day labor for the city of Toronto in 1891, at the following costs:

Average depth.	Soil.	Length, feet.	Man-holes.	Catch-basins.	Connections.	Cost per foot.
10' 10"	Quicksand	1,041	5	6	15	\$1.95
11' 2"	Clay	4,427	19	21	240	1.27
18' 0"	Blue clay	650	3	2.11
12' 1"	"	130	1	..	15	2.20
11' 6"	"	251	4	2.41
8' 1"	"	800	3	4	29	1.33
9' 9"	"	483	4	2	24	1.78
11' 2"	Clay loam	430	2	2	13	0.96
10' 8"	"	367	3	..	17	1.90
11' 0"	Hardpan	320	2	2	18	1.28
11' 3"	Sand	535	3	2	5	1.50
11' 4"	Av. of above	9,474	45	39	380	\$1.51

The cost per ft. includes all materials, labor and inspection of work. It also includes the manholes and catch-basins, and the Y-connections. The 12-in. pipe cost 22 cts. per ft.; brick was \$8.50 per M. Laborers were paid 15 cts. per hr., and a few special men were paid 18 cts. per hr.; bricklayers were paid 40 cts. per hr.

Contract Labor Costs at Providence, R. I.—During 1906 there were 2.263 miles of regular sewers built at Providence, R. I., of which 1.751 miles were of pipe and .512 miles were of brick. The average depth of cut, nature of excavation and contract cost of

labor per foot on the different sizes of sewers built during 1906 are given in the annual report of the city engineer as being as follows:

Nature of Excavation.	Average depth of cut, ft.	Average cost per ft.
6-in. pipe ¹ —Fine sand, dry	10.50	\$0.45
6-in. pipe ¹ —Fine sand, wet	10.50	.49
6-in. pipe ¹ —Sand and gravel, dry	10.50	.41
6-in. pipe ¹ —Hard pan, wet	10.50	.60
8-in. pipe ¹ —Hard pan and rock	10.50	.35
8-in. pipe ² —Fine sand, dry	8.00	.40
8-in. pipe ² —Fine sand, wet	8.00	.45
8-in. pipe ² —Sand and gravel, dry	8.00	.40
8-in. pipe ² —Hard pan, wet	8.00	.45
8-in. sewer—Fine sand, dry	11.67	.30
8-in. sewer—Sand and gravel	11.67	.70
8-in. sewer—Filling, dry	11.67	.60
12-in. sewer—Fine sand, dry	12.00	.60
12-in. sewer—Fine sand, wet	12.00	.85
12-in. sewer—Sand and gravel, dry	12.00	.62
12-in. sewer—Hard pan, wet	12.00	.60
12-in. sewer—Hard pan and rock	12.00	.35
15-in. sewer—Sand and gravel, dry	12.25	.75
15-in. sewer—Hard pan, wet	12.25	1.00
20-in. brick sewer—Hard pan and rock, wet	12.67	2.00
22-in. brick sewer—Hard pan, sand and rock, dry	12.67	.65
24-in. brick sewer—Sand and gravel, wet	13.00	3.00
30-in. brick sewer—Sand and gravel, wet	13.50	4.00
36-in. iron pipe—Mud, wet	14.00	6.50
70-in. brick and concrete—Sand and grav- el, wet	18.00	8.00
70-in. brick and concrete—Sand and grav- el, wet	"	\$0.00
84-in. brick and concrete—Mud, wet	14.00	8.00
84-in. brick and concrete—Sand and grav- el, wet	20.00	20.00

¹ In drains to curb line. ² In basin connections. ³ In tunnel.

The average labor cost of building each manhole was \$10.65, each catch-basin \$11.07, and each extra inlet \$9.00.

Brick Sewer Data.—Brick sewers are either "circular" or "egg-shape." In either case the upper part of the sewer is called the "arch," and the lower part is called the "invert." The depth of a brick sewer, as given on profiles, is the depth from the surface of the street to the inside of the bottom of the sewer, so that the thickness of the sewer invert should be added to secure the full depth of the trench. The thickness of a brick sewer is usually expressed in "rings." A "one-ring" sewer is made one brick thick; that is, 4 ins. thick plus the cement plaster which is usually ½-in. thick; so that a one-ring sewer is 4½ ins. thick. A two-ring sewer is two bricks, or 9 ins. thick. A three-ring sewer is three bricks, or 13½ ins. thick.

The size of a sewer is denoted by its inside diameter.

Brick sewers, like pipe sewers, are usually paid for by the lineal foot of sewer including trenching; but it is desirable always to calculate the brickwork in cubic yards. Table VIII gives the

number of cubic yards of brick masonry per lineal foot of circular sewer.

For intermediate sizes interpolate between the values given in the table.

To calculate the number of cubic yards per lineal foot of any circular sewer, proceed as follows: Add the inside diameter in feet to the thickness of the sewer in feet; this gives the "average diameter." Multiply this "average diameter" by $3\frac{1}{7}$, or 3.14; then multiply the quotient by the thickness of the sewer in feet and divide by 27.

For example, a 5-ft. sewer has walls 9 ins. thick (it is a "two-ring" sewer); and, as 9 ins. = $\frac{3}{4}$ ft., we have by the rule: $5 + \frac{3}{4} = 5\frac{3}{4}$ as the "average diameter"; then $5\frac{3}{4} \times 3\frac{1}{7} \times \frac{3}{4} \div 27 = \frac{1}{2}$ cu. yd. per lin. ft.

Sewer bricks are of a better quality than common building bricks, and usually cost \$1 per M more than common bricks. Ordinarily about 500 bricks are required per cubic yard, but the variation may be 15% greater or less, due to the fact that the sizes of bricks differ in different localities. About 2% is usually added to cover the wastage.

Since the joints are V-shaped, and since the inside of the sewer is usually plastered, more mortar is required than in plain brickwork. About 0.35 to 0.4 cu. yd. of mortar is required per cu. yd. of brick masonry. The number of barrels of cement required to make 1 cu. yd. of mortar is given on page 253.

In building 5-ft. circular sewers at Lawrence, Mass., in 1886, 1 part natural cement to $1\frac{1}{2}$ parts sand was used; and it required $2\frac{1}{2}$ bbls. of cement per thousand bricks.

At Newton, Mass., a 24 x 36-in. egg-shaped sewer required 1.6 bbls. of cement per cu. yd., the mortar being mixed 1:1 $\frac{1}{2}$. There were 509 bricks per cu. yd. of sewer masonry, not including the waste; and 520 bricks including waste.

At Los Angeles, two-ring 40-in. circular sewers required 0.4 bbl. Portland cement per lineal foot of sewer, which is equivalent to 1.12 bbls. cement per cu. yd. of brick masonry. The mortar was 1 part cement to 2 parts sand.

Mr. Desmond Fitzgerald gives the following as averages of cost of brick sewer work done by certain contractors at Boston, prior to 1894:

	—Per cu. yd.—	
Labor	\$ 2.89	\$ 3.46
Brick (560 to 580 per cu. yd.), at \$9.50 per M	5.48	5.30
Sand	0.30	0.40
Natural cement, 1.27 bbls., at \$1.13	1.35	1.50
Centers	0.23	.20
Miscellaneous	0.19	.20
Total per cu. yd.....	\$10.44	\$11.00

The first example is the cost of a well-handled job of 1,300 cu. yds. of brick masonry. The second example is the average of several jobs. Brick cost \$9.50 per M; and natural cement \$1.13 per bbl. The mortar was probably mixed 1:1 $\frac{1}{2}$, that is 1 part

cement to $1\frac{1}{2}$ parts sand. Wages of bricklayers were probably 50 cts. per hr., and helpers 15 to 20 cts. per hr.

TABLE VIII.—BRICK MASONRY IN CIRCULAR SEWERS, CU. YDS. PER LINEAL FT.

Diameter, Ft. Ina.	One-Ring (4½ Ina.)	Two-Ring (9 Ina.)	Three-Ring (13½ Ina.)

54 x 81561	.891
56 x 84579	.918
58 x 87598	.946
60 x 90616	.973

Bricklayers on sewer work often receive abnormally high wages. In some cities the labor unions have forced up the price to \$1 per hour. In such cases a bricklayer is usually required to lay not less than 3,000 or 4,000 bricks a day; and I have known as high as 5,000 bricks to be laid by skilful and rapid layers.

The dimensions of egg-shaped sewers are given in terms of the inside diameter of the upper arch, and the inside height of the sewer; thus a 30 x 45-in. sewer, is one having an upper arch 30 ins. inside diameter and an inside height of 45 ins. The Phillips Metropolitan Standard (English) egg-shaped sewer has an inside height which is $1\frac{1}{2}$ times the diameter of the arch. Calling the diameter of the arch d , the other dimensions are:

Radius of invert.....	$\frac{1}{2} d$
Radius of side.....	$1\frac{1}{2} d$
Height	$1\frac{1}{2} d$
Area of waterway.....	$1.15 d^2$
Perimeter	$3.96 d$

The first dimension given in the first column of Table VIII is d . The table gives the number of cubic yards of masonry per lin. ft. of egg-shaped sewer.

Cost of Large Brick Sewers, Denver, Colo.—Mr. W. W. Follett gives the following data on brick and concrete sewers built by day labor in Denver, Colo.: Work was begun August, 1894, and finished June, 1895. Work was carried on in the winter, which added somewhat to the cost. The wages paid were high and the hours of labor short. The men were considered to be efficient. The following were the number of day's work performed and the wages per 8-hr. day:

726 days, foremen, at \$3.33 $\frac{1}{2}$ to \$5.
1,398 days, stone masons, at \$3.60.
1,491 days, brick masons, at \$4.00.
385 days, watchmen, blacksmiths, and timbermen, at \$2.50.
8,115 days, labor, at \$2.00.
7,628 days, labor, at \$1.75.
363 days, waterboys, at \$1.00 to \$1.25.
2,150 days, team with driver, at \$3.50.
252 days, enginemen and pumpers, at \$3.00.

See Table X.

Note.—Sec. 1 was built in filled ground containing city refuse. The original ground was about level with the invert, and had been filled with 2 to 5 ft. of refuse. The bottom of the trench was 2 to 4 ft. below the level of a river near by, so that there was much pumping. The backfill was largely hauled in with wagons, as the material from the trench was not a suitable backfill. The sewer had a concrete base 8 ins. thick and 16 ft. wide, on top of which was a stone cradle. The invert was a single ring of brick, and the arch was three rings.

Sec. 3 was nearly all in good ground, but there was water all along it. The cross-section of the sewer was the same as in Sec. 1, except with less diameter, giving about 80% as much material.

Sec. 6 contained rock for its full length, but the rock was very soft, being in places hardly more than indurated clay. The trench

TABLE X.—COST OF BRICK AND CONCRETE SEWERS, DENVER, COLO.

Total	\$20.191	\$16.515	\$9.410	\$10.815	\$12.567	\$12.292	\$12.956	\$12.580	\$12.580

Note.—Sec. 1 was built in filled ground containing city refuse. The original ground was about level with the invert, and had been filled with 2 to 5 ft. of refuse. The bottom of the trench was 2 to 4 ft. below the level of a river near by, so that there was much pumping. The backfill was largely hauled in with wagons.

averaged 11 ft. deep, and was timbered all along. No water was encountered. The sewer was three-ring brick.

Sec. 7 was similar in every way to Sec. 6, except that a loose sand overlaid the rock.

Sec. 8 was in gravel containing much water. The cut averaged 12½ ft. deep.

Sec. 9 was in fine, loose sand, heavily charged with water. The average cut was 14 ft. deep.

The concrete foundations were made 1:3:6 Portland cement and crushed, unscreened sandstone. The stone was estimated on a basis of 2,500 lbs. per cu. yd. Concrete was hand mixed and delivered in wheelbarrows. The average cost of 1,545 cu. yds. of concrete was as follows:

0.733 bbl. cement	\$2.548
0.754 cu. yd. stone	1.409
0.424 cu. yd. sand	0.148
Water	0.007
Labor (\$1.75 an 8-hr. day).....	0.703

Total per cu. yd.....\$4.810

The stone cradle was built of a soft sandstone which broke out square in the quarry so that little hammering was required in the trench. It was bought by the ton. Louisville (natural) cement, weighing 265 lbs. per bbl., was used in a 1:2 mortar. The average cost (not including engineering) of 6,428 cu. yds. of this stone cradle was as follows:

1.297 cu. yds. of rubble.....	\$1.975
0.875 bbl. natural cement.....	1.281
0.305 cu. yd. sand.....	0.130
Water	0.005
Labor (masons, \$3.60; laborers, \$3.00, for 8 hrs.)	1.284

Total per cu. yd.....\$4.655

The invert brick ring of Sec. 3 was laid in 1:3 Portland mortar, and the same mortar was used in plastering. On Secs. 1, 2 and 5 a 1:2½ Louisville mortar was used; and on Secs. 6, 7, 8 and 9, a 1:3 Louisville throughout.

The amount of cement per cubic yard of brickwork, by sections, was as follows: Sec. 10, 0.835 bbl.; Sec. 3, 1 bbl.; Sec. 5, 1.07 bbls.; Sec. 6, 0.87 bbl.; Sec. 7, 0.937 bbl.; Sec. 8, 0.99 bbl.; Sec. 9, 0.976 bbl. Assuming that the 1:2½ mortar required 2½ bbls. cement per cu. yd. of mortar, it would require 0.4 cu. yd. of mortar per cu. yd. of brick masonry when it took 1 bbl. of cement per cu. yd. of brick masonry.

The number of brick per cubic yard ranged from 431 on Sec. 3 to 450 on Sec. 6. The average cost of 6,702 cu. yds. of brickwork on all sections was as follows, per cu. yd.:

439 brick	\$4.584
0.92 bbl. cement	1.953
0.41 cu. yd. sand.....	0.198
Miscellaneous	0.229
Labor	2.384

Total per cu. yd.....\$9.348

The labor cost ranged from \$2 per cu. yd. on Secs. 1 and 3 to \$2.95 on Sec. 9.

One foreman handled 18 bricklayers, divided into three gangs, the total number of his force, including helpers and laborers, being 80 men.

A neat form of steel centering was designed and used as follows: Light, 8-lb., dump-car rails were bent so as to form half-rings; the lower half-ring (or semi-circle) being bent with the

Fig. 4. Centers for Concrete Sewer.

head of the rail facing out, and the upper half-ring with its head facing in, as shown in Fig. 4. A short piece of rail was laid with its flange against the flange of the lower half-ring and riveted. One of these short pieces of rail was thus riveted at each end of the lower half-ring. Thus it was possible to butt the ends of the upper half-ring against these short pieces of rail riveted to the lower half-ring, and connect the two with fish-plates and bolts. In order to be able to "strike" (remove) these steel centers, a bevel-joint was made, as shown in the figure. This was done by sawing one end of the upper half-ring across on a bevel, and sawing a

similar bevel on the end of the short piece of rail against which it butted. After the fish-plate bolts were removed, a blow of a hammer would readily knock the two half-rings apart at the bevel-joint. It will be noted that the 2-in. lagging was laid upon the flange of the upper half-ring, no lagging being used on the lower half-ring, as the invert was built of brick.

To hold the lagging to the upper half-ring, it was found best to make little iron clips, three of which were fastened to the underside of each 12-ft. stick of lagging, using two wood screws for each clip. The end of the clip slipped over the flange of the steel rail, but was not screwed or bolted to the rail, so that each stick of lagging was quickly removed by shoving it endwise. These steel centers or rings were placed 2 ft. 6 in. apart, c. to c., so that 40 rings sufficed to set up centers for 96 ft. of sewer. Two men would take down, clean and set up 96 ft. of this centering in a day, making the cost of moving centers about 4 cts. per ft. of sewer. In building 8,290 ft. of sewers, three sets of steel centers and two sets of lagging were used, costing \$775 for materials and labor of making, or 9.3 cts. per ft. of sewer, making a total cost of a little over 13 cts. per ft. of sewer for making and moving lagging and material. There were only three sets of rings because there were only three sizes of sewers, 70, 77 and 94-in.

Cost of an Egg Shaped Sewer, Springfield, Mass.*—The Worcester St. sewer, for which cost data are given below, was built at Springfield, Mass., during December, 1904, and January, 1905. It consists of 670 ft. of 1 ft. 10 in. by 2 ft. 9 in., egg-shaped brick sewer and two manholes. The sewer was laid in a gravel trench at an average depth of 9.8 ft., the grade being 6 in. per 100 ft. The loose character of the gravel necessitated tight sheeting of the trench all of the way.

The invert of the sewer was constructed of 8-in. brickwork, but the arch was of a single ring or 4-in. brick, plastered outside with 1 in. of cement mortar, Portland cement being used throughout.

At the time the work was done there was about 2½ ft. of frost in the ground, and consequently coke fires were built along the line of excavation in advance of the work. These fires required about \$45 worth of wood and 536 bushels of coke at 11 cts. per bushel.

The excavation was done by pick and shovel, and the trench was backfilled as fast as the mason work was completed. The work was done by the city by day labor.

The wages paid per 8-hour day were as follows:

Foreman	\$3.00
Bracers	2.00
Laborers	1.75
Teams	4.50
Masons	5.00
Mason tenders.....	2.40

**Engineering-Contracting*, Jan. 16, 1907.

The cost of the work is shown in the following tabulation:

<i>Labor.</i>		Per lin. ft.
Excavating and refilling.....		\$1.40
Sheeting23
Masons36
Tenders20
Total labor.....		\$2.19
<i>Material</i>		
Brick, \$9.20 per M.....	\$.79
Cement, at \$1.60.....		.36
Manhole castings and steps.....		.02
Sheeting lumber, at \$22.50.....		.05
Wood07
Coke (538 bu.).....		.09
Profiles and centers.....		.01
Total materials.....		\$1.39
Grand total.....		\$3.58

The labor cost of constructing the brickwork was as follows:

	Per lin. ft.	Per cu. yd.
Masons, 42 $\frac{3}{4}$ days.....	\$0.36	\$2.14
Tenders, 57 $\frac{1}{4}$ days.....	.20	1.19
Total	\$0.56	\$3.32

On the work there were usually two masons and three tenders.

Cost of a 7-Ft. Brick Sewer, Gary, Ind.*—In trenching for a 7-ft. sewer through water soaked sand at Gary, Ind., the sand is being unwatered by driving well points and pumping. The method has enabled what promised to be a difficult task to be accomplished with comparative ease. Only a moderate amount of sheeting has been necessary and practically no caving has resulted.

The sand through which the work passes is very fine, such a sand as forms the dunes of Michigan and other states bordering Lake Michigan. When water soaked it takes a slope of about 1 on 15. At Gary this fine sand is water soaked to within a few feet of the surface; in places water covers the surface. So far as excavation work goes the material is to all intents and purposes a quicksand.

In brief, the method of work adopted is as follows: A wide shallow trench is excavated by a drag, scraper bucket excavator of the Page & Shnoble type to about water level, say to a depth of 6 to 8 ft. Bleeding is then begun. A 4-in. pipe 132 ft. long in six 22-ft. sections is stretched along the center line of the sewer. On each side of this pipe about 3 ft. away is sunk a row of well points 2 ft. apart. These well points are 3 ft. long and are attached to 13-ft. pipes. The tops of the driven pipes are connected by hose to the 4-in. pipe line which has cross-valves for the purposes. A pump connects with the 4-in. pipe line and also with a 4-in. well point sunk vertically underneath. An extension of the 4-in. pipe line with strainer end also takes the surface water from a sump.

This battery of well points lowers the water so that a further excavation of 6 to 8 ft. can be made between sheet piling. A second

**Engineering-Contracting*, Aug. 5, 1908.

battery of well points is then sunk at this new level. In this battery, however, the points are sunk close to the sheeting and each row feeds into a separate 2-in. pipe along the trench. This battery lowers the water level enough to permit excavation to sub-grade, which is some 6-ft. below the bottom of the sheeting. The brick sewer is then built in the usual manner and the back-filling done by means of a derrick and Hayward clam shell bucket.

The diagram Fig. 4A shows the general plan of procedure described. In this description details have been neglected to prevent confusion; some of these details, however, require description.

Scraper Bucket Excavator Work.—The bucket is of 3 cu. yds. capacity and is operated on a 58-ft. boom with the usual cable and chain attachments. The sand being excavated is wet; that is, the voids are filled with water. The amount of excavation is 10 cu. yds. per running foot of trench, and the machine makes 60 ft. per day. This 60 ft. is not its capacity, but is the distance made daily by

Fig. 4A

all the work and the excavator is worked just enough to keep pace. The depth being excavated is also limited by water level.

The machine is mounted on rollers traveling on a track of timbers. One merit of the machine is that some of the excavated material can be dumped straight ahead in the path of the work so that it builds its own roadbed over the swamps in front. The machine is pulled ahead by simply lowering the bucket and letting it get a good bite in the ground ahead, then pulling on the digging cable.

The excavator is taking out about 400 cu. yds. per 9-hour day, with a gang of 1 engineer, 1 fireman and 4 laborers.

First Battery of Well Points —Referring to Fig. 4A it will be seen that the first battery of well points occupies a narrow space along the center of the trench; this permits the sheeting to be driven outside of the well points. The well points are 2 ins. x 3 ft., and they are attached to 2-in. x 13-ft. pipes with ell at their tops. A 4-ft. length of wire lined hose is attached to each ell. These points are sunk vertically by jetting. Two men were timed in jetting. They used 1-in. jetting pipes with about 100 lbs. water pressure and sunk four points in one minute. This time did not

include making connections. In addition to the two rows of 2-in. points, a 4-in. point is sunk directly under the pump.

The well points are connected by the short hose lengths to a 4-in. horizontal suction pipe. Six 22-ft. sections of suction pipe are used with flanged joints. Each section has 11 cross-valves with double bushings for the hose connections. A gate valve near the end of each section permits the rear-sections to be removed and placed ahead as fast as the work progresses. An extension of the 4-in. suction pipe forward to a sump in the excavation being made by the scraper bucket handles the surface water.

The water is drawn from the suction pipe by an Emerson No. 3 pump with 5-in. suction and 4-in. discharge. The pump is hung to a chain fall from an A-frame mounted on rollers. It discharges into a tile drain alongside the trench; this drain leads back to the completed sewer discharging behind a temporary dam of bags of sand inside the sewer. Summarized, the first battery of well points is composed as follows:

- 1 No. 3 Emerson pump.
- 1 4-in. well point sunk below pump.
- 132 2-in. well points sunk in two rows.
- 1 4-in. suction pipe with extension to surface water sump.

Sheeting Trench.—The trench is sheeted 10 ft. wide, the sheeting being carried along so as to embrace about one section (the rearmost) of the first battery of well points. The sheeting is 2 x 8-in. x 12-ft. planks and is driven by mauls. Walling pieces and trench braces are placed as the excavation proceeds. This excavation is carried down about 6 ft. by shovelers and at this level the second battery of well points is placed. The sheeting is pulled as the back filling proceeds.

Second Battery of Well Points. The second battery of well points consists of two rows like the first, but the rows are placed wide apart (close inside the sheeting on both sides) and each has a separate suction pipe. The suction pipes are 2 ins. in diameter and the well points are 1½ ins. in diameter; the well points and pipes are 16 ft. long and when sunk they penetrate a couple feet or so below sub-grade and 6 ft. below the bottom of the sheeting. The suction points are made in sections with hose connections every two feet and gate valves at the ends.

Two pumps operate the second battery of well points; they are of the same size and make as that for the first battery and are suspended similarly. Each pump draws water from both rows of well points and also from a 4-in. well point sunk directly under the pump. This is accomplished by means of a four-way connection in the suction of each pump, about 1 ft. below the pump. From this connection 2-in. pipes branch right and left to connections with the 2-in. suction pipes and a third connection is made with the 4-in. well point. Operating in parallel the two pumps can, by means of the gate valves, concentrate their work on those portions of the battery of well points where especially large quantities of water are encountered or can pump from the whole system, also either

one of the pumps can be cut out. These pumps discharge into the same tile drain as the first pump.

The methods of advancing the second battery of well points is substantially the same as for the first; that is, the rear sections of suction pipe and well points are detached and placed in front. Generally the forward end of the second battery is kept far enough ahead to overlap the rear section of the first battery.

Excavation and Sewer Construction.—The deepening of the trench at the rear end of the second battery of well points is done by hand. So perfect is the drainage that it is found possible to excavate some 6 ft. deeper than the bottom of the sheeting, and to construct the brick sewer in the trench bottom with no more seepage than can be handled by a fourth Emerson pump, which takes water from a sump and discharges behind the temporary sand bag dam mentioned previously.

Backfilling.—The backfilling is done from the spoil bank. As fast as the sewer is completed, shovelers cover it with a layer of sand. The remainder of the backfilling is done by an 8¼ x 10-in. Lidgerwood engine and derrick operating a 1 cu. yd. Hayward clam shell. This machine puts in about 500 cu. yds. of backfill in 9 hours at a labor cost of about 4 cts. per cu. yd. figured as follows:

1 engineman at \$5.....	\$ 5.00
1 fireman at \$3.....	3.00
8 laborers at \$2.....	6.00
Fuel at \$3 60 per ton.....	6.25

Total 500 cu. yds. at 4 cts.....\$20.25

Sheeting and Bracing.—Two rows of 2 x 8-in. x 12-ft. sheeting 60 ft. long are driven, braced and pulled per 9-hour day with the following gang:

4 men setting braces at \$2 25	\$ 9.00
3 men driving sheeting at \$2.50.....	7.50
4 men pulling sheeting at \$2.50.....	10.00
1 carpenter at \$3.....	3.00

Total\$29.50

This gives a cost of 24¼ cts. per lineal foot of 12-ft. sheeting driven, braced and pulled, not including materials and superintendence, etc.

Pumping and Changing Piping.—The pumping is continuous day and night, but the jetting of well points and changing of piping is confined to the regular shift of 9 hours. The gang worked is as follows:

14 pipe line men at \$2.25.....	\$31.50
10 firemen (two shifts) at \$3.....	30.00
2 foremen at \$3.....	6.00
6 laborers at \$2.....	12.00
Coal for 24 hours (estimated).....	15.00

Total\$94.50

This gives a cost of \$1.57 per lin. ft. of trench, not including superintendence, interest, depreciation, etc.

Trench Excavation.—The trench excavation, excluding scraper bucket works, runs about 300 cu. yds. per day, assuming 60 ft.

of 10.5 x 13 ft. trench per 9 hours. This work is done by 85 shovelers at \$2 per day, and costs $\$170 \div 300 \text{ cu. yds.} = 56.6 \text{ cts. per cu. yd.}$

Miscellaneous.—The cost of clearing the right of way amounts to \$4 per day, 2 men at \$2 being employed. There are 3 waterboys at \$1, or a charge of \$3 per day for waterboys.

Summary.—Summarizing we have the following costs for trench work complete and ready for sewer construction:

	Per day	Per lin. ft.
Scraper excavator work (400 cu. yds.)....	\$ 22 25	\$0.370
Shovel excavation (300 cu. yds.).....	170 00	2.833
Sheeting and bracing (300 cu. yds.).....	29 50	0.491
Pumping and pipe system (300 cu. yds.)...	94 50	1.575
Backfilling (500 cu. yds.).....	20 25	0.337
Miscellaneous (300 cu. yds.).....	7 00	0.116
Total	\$343.50	\$5.722

Figured on a cubic yard basis these costs may be arranged as follows:

	Per cu. yd.
Scraper work, including clearing (400 cu. yds.)..	\$0.055
Trenching, pumping and sheeting (300 cu. yds.)	0.980
Backfilling (500 cu. yds.).....	0.040

Brick Sewer Construction.—About 80 ft. of sewer are completed per 9-hour day. The labor and materials cost of this work runs about as follows:

<i>Materials.</i>		Per day.
30,000 brick at \$6.50.....		\$195.00
30 bbls. Portland cement at \$1.75.....		52 50
30 bbls. Utica natural cement at \$1.....		30.00
Total materials.....		\$277.50
<i>Labor.</i>		
5 men mixing mortar....	\$2 50	\$ 12.50
5 men carrying cement mortar.....	2 50	12.50
3 men lowering cement mortar.....	2 25	6.75
6 brick masons (5,000 brick each daily)	10.00	60.00
3 brick tenders.....	3.75	11.25
15 brick handlers (av.).....	2.50	37.50
26 men on industrial railway.....	2.00	52.00
3 teamsters	2 50	7.50
3 teams	9.00	27.00
3 form setters	3.25	9.75
3 water boys.....	1.00	3.00
Total labor		\$249.75
Total labor and materials.....		\$17.25

Assuming 500 brick per cubic yard of masonry, these figures give a cost of:

	Per cu. yd.
Materials	\$4.62
Labor	2.99
Total	\$8.62

About 2 bbls. of cement were required per 1,000 brick laid, and the cost per 1,000 brick laid was \$17.24.

The cost of superintendence on the work runs about \$50 per day, and repairs, waste and depreciation aggregate about \$40 per day.

In reviewing these figures it must be kept in mind that they omit a number of costs. For example, the cost of lumber for sheeting, runways, etc., and the cost of lumber and construction for centers are not included. Other lacking items will be noted by those familiar with such work. Though incomplete as noted the figures will, we believe, prove decidedly interesting in connection with the novel methods of work adopted.

[The costs are given in greater detail in the following paragraphs.]

Cost of a Brick Sewer in Water-Soaked Sand at Gary, Ind.*—In our issue of Aug. 5, 1908, we described in some detail the construction of a sewer in water soaked sand at Gary, Ind. The method adopted was to unwater the sand by bleeding—by sinking well points in the sand along the line of the sewer and drawing out the water with pumps. At the time this description was published the construction had not been completed nor the costs fully analyzed, so that the costs then published were only approximate. Since then the cost of the work has been worked out in considerable detail by City Engineer A. P. Melton and his assistant, Mr. E. M. Scheflow, and has been placed at our disposal by Mr. Melton.

The costs were compiled by keeping a force and time account of the work. The inspector kept the records on blanks prepared for the purpose and checked them with the books of the contractor's timekeeper. While some items of cost familiar to the contractor were not thus included, yet the figures given may be considered very close approximations.

The work comprised 4,258 ft. of brick sewer, ranging from 7 ft. circular section to 8 ft. 4 in. by 8 ft. 11 in. oval section, all with shells consisting of 2½ rings of brick. The soil was fine sand water soaked below a level about 22 ft. above subgrade; the water-soaked sand ran on a slope of about 1 on 15. The trench ranged from 18 to 30 ft. in depth. The method of excavation was fully described in our issue of Aug. 5. Briefly a preliminary wide cut was made some 5 to 16 ft. deep with machines, then well points were sunk and the ground drained, after which excavation proceeded by hand between sheeting. The masonry work and backfilling followed. The cost of construction was divided into the following items: Machine excavation, sheeting, pumping, hauling materials, sewer building, backfilling, materials and organization.

Machine Excavation.—The preliminary wide shallow cut only was excavated by machine. A ¾ cu. yd. Hayward orange peel bucket operated by a 25-hp. engine was used for the first 1,900 ft. and took out 21,250 cu. yds. at the following cost:

Item.	Total.	Per cu. yd.
Engineer, 56 days, at \$6....	\$ 336.00	\$0.0153
Fireman, 56 days, at \$3.50....	196.00	0.0092
Laborers, 255 days, at \$1.75.	446.25	0.0210
Coal, 66 shifts, at \$5.....	280.00	0.0131
Total	\$1,258.25	\$0.0686

At this point the orange peel was removed to the rear to work on backfilling and a Page & Schnable drag scraper excavator was

* *Engineering-Contracting*, Oct. 7, 1908.

substituted. This machine had a 2 cu. yd. bucket and a 40-hp. engine; this engine was found to be too weak and was used only until a larger one could be secured. Another objection to the first arrangement was that two men were required to operate the bucket, one at the hoist and one at the swing engine. With the machine as first equipped and operated 15,300 cu. yds. of material were excavated at the following cost:

Item.	Total.	Per cu. yd.
Engineer, 31 days, at \$6	\$186.00	\$0.0122
Fireman, 31 days, at \$3.50....	108.50	0.0071
Engineer, 31 days, at \$3.....	93.00	0.0060
Laborers, 118 days, at \$1.75....	206.50	0.0138
Coal, 31 shifts, at \$5.....	155.00	0.0101
Total	\$749.00	\$0.0492

The 40-hp. engine was replaced by one of 60 hp., so arranged that one man operated both hoist and swinging engine. With the remodeled outfit 11,000 cu. yds. of material were excavated at the following cost:

Item.	Total.	Per cu. yd.
Engineer, 21 days, at \$6.....	\$126.00	\$0.0114
Fireman, 21 days, at \$3.50....	73.50	0.0067
Laborers, 84 days, at \$1.75. .	147.00	0.0133
Coal, 21 shifts, at \$5.....	105.00	0.0095
Total	\$451.50	\$0.0409

It will be seen that the change of the engines reduced the cost per cubic yard by the amount of the wages of one engineer; the saving was 0.83 cts. per cu. yd. Summarizing we have a cost of \$2,488.75 for excavating 47,550 cu. yds., or of \$0.0523 per cu. yd. For the 4,258 ft. of sewer the cost was 57.9 cts. per lin. ft.

Hand Excavation.—The bottom 13 ft. in depth of the trench was excavated by hand between sheeting, the width of the excavation was approximately 10 ft. The cost of the work was as follows:

Item.	Total.	Per cu. yd.
Laborers, 6,441 days, at \$2..	\$12,882.50	\$0.5413
Foreman, 84 days, at \$3....	522.00	0.0232
Total	\$13,434.00	\$0.5645

The total amount of hand excavation was 23,800 cu. yds.

Sheeting.—The sheeting consisted of vertical 2 x 8-in. by 12-ft planks held by two pairs of 6 x 8-in. waling pieces and 9-ft. cross braces spaced 8 ft. apart. In cases of very wet trench a third row of waling and braces was put in, occasionally, also, horizontal sheeting was used in the bottom. The cost of driving the sheeting and placing the bracing and also of pulling it was as follows:

Placing.	Total.	Per lin. ft.
Laborers, 882 days, at \$2.....	\$1,764	\$0.4142
Foreman, 80 days, at \$3.50....	280	0.0658
Carpenters, 50 days, at \$3.....	150	0.0351
Total	\$2,194	\$0.5151
Pulling:		
Laborers, 242 days, at \$2.....	\$ 484	\$0.1136
Grand total	\$2,678	\$0.6287

Pumping.—The item of pumping comprises all the work of sinking and shifting the well points and pipe line and the removal of the backwater in the finished part of the sewer. Three Emerson pumps took water from the well points, a fourth handled the backwater and a duplex pump furnished water for boilers, mixing mortar, jetting, etc. The cost was as follows:

Item.	Total.	Per lin. ft.
Laborers, 542 days, at \$1.75..	\$ 948.50	\$0.2227
Pipe line men, 958 days, at \$2.50	2,395.00	0.5625
Total for pipe work.....	\$3,343.50	\$0.7852
Coal, 100 days, at \$15.....	\$1,500.00	\$0.3499
Firemen, 855 days, at \$3.50..	2,992.50	0.7025
Total for pumping.....	\$4,492.50	\$1.0524
Grand total	\$7,836.00	\$1.8376

Pumping costs and pipe line costs have been separated, since the first is a continuous expense which does not vary from day to day, and the second cost is operative only when construction is actually going on.

Hauling Brick and Other Materials.—The materials were hauled 1,500 ft. in steel dump cars running on portable track; the cars were pushed by hand. Coal, lumber, supplies, etc., purchased from local dealers, were hauled by team. The cost of hauling was as follows:

Item.	Total.	Per lin. ft.
Laborers, 1,219 days, at \$2.....	\$2,438	\$0.5725
Foreman, 80 days, at \$3.50.....	280	0.0657
Teams and drivers, 180 days, at \$5.50	990	0.2322
Total	\$3,708	\$0.8704

Sewer Construction.—The construction of the 4,258 ft. brick sewer was as follows:

Item.	Total.	Per lin. ft.
Laborers, 1,506 days, at \$2..	\$ 3,012.00	\$0.7073
Carpenters, 50 days, at \$3..	150.00	0.0351
Form setters, 225 days, at \$3.75	843.75	0.1981
Bricklayers, 471 days, at \$10	4,710.00	1.1061
Scaffold men, 236 days, at \$2.75	649.00	0.1524
Brick tenders, 236 days, at \$3.75	885.00	0.2076
Mortar mixers, 387 days, at \$2.25	860.75	0.2021
Total	\$11,110.50	\$2.6087

As noted further on, the cost of brick and cement for the job was \$14,436.50, or \$2.384 per foot of sewer, making the total cost for labor and materials \$4.993 per lin. ft. Since there were 520 bricks per lin. ft. of sewer, the cost per cubic yard of the brickwork was approximately the same as the cost per lineal foot. The bricklayers averaged 4,710 bricks per man per 9-hr. day. Two barrels of cement were used per 1,000 bricks.

Backfilling.—Enough backfilling was done by hand to cover the sewer and to permit the sheeting to be pulled; the remainder was done with the clam-shell excavator first used for preliminary trenching. The cost of backfilling by hand was as follows:

Item.	Total.	Per lin. ft.
Laborers, 378 days, at \$2.....	\$756	\$0.18

The cost of backfilling by machine was as follows:

Item.	Total.	Per lin. ft.
Laborers, 207 days, at \$1.75....	\$537.25	\$0.1261
Engineers, 93 days, at \$6....	558.00	0.1287
Firemen, 93 days, at \$3.50....	326.50	0.0764
Coal, 93 shifts, at \$5.....	465.00	0.1092
Total	\$1,885.75	\$0.4404

Materials.—The cost of the materials used in the job was as follows:

Item.	Total.	Per lin. ft.
2,221,000 brick, at \$5.....	\$11,105.00	\$2.6080
Union cement, 6,663 sacks, at 20 cts.	1,332.60	0.3106
Universal cement, 6,663 sacks, at 30 cts.	1,998.90	0.4694
30 M ft. B. M. lumber, at \$20	600.00	0.1409
Total	\$15,036.50	\$3.5289

Superintendence and General Expenses.—The costs of superintendence and general expenses were as follows:

Superintendence.	Total.	Per lin. ft.
Superintendent, 4 mos., at \$150..	\$ 600	\$0.1409
Gen'l foreman, 4 mos., at \$125..	500	0.1174
Master mechanic, 4 mos., at \$200	800	0.1855
Timekeeper, 3 mos., at \$60.....	180	0.0422
Team, 100 days, at \$4.....	400	0.0927
Total	\$2,480	\$0.5787
General expenses.		
Waterboys, 220 days, at \$1.50..	\$ 330	\$0.0775
Clearing right of way, 60 days at \$150	90	0.0211
Total	\$ 420	\$0.0986

Summarizing we have the cost per lineal foot of sewer as follows:

Item.	Per lin ft.
Excavation by machine	\$ 0.58
Excavation by hand.....	3.16
Sheeting	0.63
Hauling brick and other materials.....	0.87
Pumping	1.84
Laying brick sewer.....	2.61
Backfilling by hand.....	0.18
Backfilling by machine.....	0.44
Materials	3.53
Superintendence and general.....	0.68
Depreciation, repairs, setting up machines	1.60
Making 3 railway crossings (\$2,500)....	0.58
Total	\$16.59

The work was begun on April 2 and was completed on Aug. 5.

1908, during which time only 11 days were lost by the bricklayers.

Cost of a 66-in. Brick Sewer at Gary, Ind.*—The methods and cost of constructing a brick sewer of oval section, 6 ft. 2 ins. x 8 ft. 11 ins. in size, at Gary, Ind., were published in our issues of Aug. 5 and Oct. 7, 1908. This oval section changes to a circular section 66 ins. in diameter and then to a circular section 60 ins. in diameter, which continue the sewer inland. The costs of the circular sections, 4,062 ft. long, have recently been compiled from inspectors' and timekeepers' reports by City Engineer A. P. Melton and Assistant Engineer E. M. Scheflow and are given us for publication.

The land through which the sewer passes consists of alternating ridges and marshes differing in elevation about 10 ft. The trench, therefore, varied in depth between a maximum of 24 ft. and a minimum of 14 ft., and averaged 17 ft. in depth. The material trenched was a fine sand saturated with water to a height of 13 to 14 ft. above the bottom of the trench. The water-soaked sand was very unstable, taking a slope of about 1 on 15 when unconfined.

The method of excavation was to take out a wide cut between natural banks to about waterline level, then to drive sheeting and excavate between it to subgrade. To permit excavation between sheeting the sand was freed of its water to below sub-grade level by sinking batteries of well points and pumping. Full details of the bleeding plant were given in our issue of Aug. 5, 1908. The wide surface cut was made with a drag bucket excavator, with two objects, to get a wide working space, and to reduce the depth of sheeting.

Construction was begun Aug. 1 and finished Oct. 1, 1908. Laborers on excavation sheeting, pumping, etc., worked a 10-hour day; tenders, cement mixers and helpers to bricklayers worked a 9-hour day; bricklayers worked an 8-hour day; firemen on pumps worked in 12-hour shifts, and excavating machine crews worked a 9-hour day. The costs of the various items of the work were as follows:

Drag Bucket Excavator Work.—The preliminary cut was about 30 ft. wide, and from 4 to 10 ft. deep; there were 33,350 cu. yds. of excavation for the 4,062 ft. of sewer or about 8.21 cu. yds. per lin. ft. The excavator worked 835 shifts and so averaged nearly 400 cu. yds. per shift of 9 hours. The cost of operating the excavator was as follows:

Item.	Per 9-hr shift.
1 engineman, at \$6.....	\$ 6.00
1 fireman, at \$3.50.....	3.50
4 laborers, at \$2.....	8.00
Coal (estimated)	5.00
Oil, repairs, etc.....	2.00
Total	\$24.50

This gives a cost of 6.1 cts. per cu. yd. of excavation and of 50.3 cts. per lin. ft. of sewer.

**Engineering-Contracting*, Jan. 27, 1909.

Excavation by Hand.—The excavation between sheeting, approximately $8\frac{1}{2} \times 10$ ft., was done by hand, scaffolding the material from 3 to 5 times and an average of 4 times. The cost of the work was as follows:

Item.	Total.
Foreman, 51 days, at \$3.25.....	\$ 165.75
Laborers, 2,184 days, at \$2.25.....	4,914.00
Total	\$5,079.75

This gives a cost of 39.4 cts. per cu. yd., and of \$1.25 per lin. ft. of sewer.

Pumping.—The pumping plant consisted of 3 No. 3 Emerson pumps drawing from the well points; 1 No. 2 Emerson pump taking water from the pools formed behind the drag bucket excavator; 1 duplex pump for boiler feed, jetting points, wetting brick, etc., and 4 30-hp. horizontal boilers mounted on wheels. This plant worked continuously. The cost of operation was as follows:

Item.	Total.
Laborers, 464 days, at \$2	\$ 928.00
Fireman, 439 days, at \$3.50.....	1,536.50
Pipe linemen, 1,238 days, at \$2.50.....	3,094.00
Foreman, 27 days, at \$3.50.....	94.50
Coal, 60 days, at \$15 (estimated).....	900.00
Total	\$6,553.00

This gives a cost per lineal foot of sewer of \$1.61 for pumping. Charged entirely against the excavation between sheeting which was closely 12,893 cu. yds., the cost of pumping per cubic yard of excavation was 50.8 cts.

Sheeting.—The sheeting consisted of 2x8 in. x 12 ft. plank driven close on each side of the trench. This sheeting was braced apart by two 6x8 in. walling pieces set 3 ft. apart vertically and 6x8 in. x 8½ ft. cross-braces spaced 8 ft. apart along trench. The cost for sinking, bracing, pulling and bringing forward was as follows.

Item.	Total.
Labor, placing and driving, 392 days, at \$2.25	\$ 882.00
Labor, pulling and bringing ahead, 182 days, at \$2.25.....	409.50
Foreman, 27 days, at \$3.50.....	94.50
Carpenter, 36 days, at \$3.....	108.00
Total	\$1,494.00

This gives a cost for sheeting of 36.8 cts. per lin. ft. of trench and of 11.6 cts. per cu. yd. of excavation between sheeting. There were about 73 ft. B. M. of sheeting and bracing per lineal foot of trench, so that the cost per M. ft. B. M. was practically \$5 for labor placing, pulling, etc.

Laying Brick Sewer.—The sewer was built of two rings of brick. The invert was built in 24-ft. sections. Wooden centers with lagging 16 ft. long were used in laying the arch and 2 men knocked the

centers down, brought them forward and re-erected them as fast as 6 bricklayers could work. The cost of laying was as follows:

Item.	Total.
Bricklayers, 223 days, at \$10.....	\$2,230.00
Tenders, 112 days, at \$3.75.....	420.00
Scaffoldmen, 111 days, at \$2.75.....	306.25
Mortar mixers, 225 days, at \$2.50.....	562.50
Form setters, 100 days, at \$3.75.....	375.00
Laborers, 715 days, at \$2.....	1,430.00
Carpenter, 18 days, at \$3.....	54.00
Total	\$5,376.75

This gives a cost of \$1.32 per lin. ft. of sewer and of \$5.28 per 1,000 bricks laid.

Backfilling.—The backfilling to a height of 2 ft. above the brick-work was done by hand, and for the remainder of the height by a 1-cu. yd. Hayward clam shell excavator. The backfilling by hand called for 277 days' labor at \$2 and cost, therefore, \$554 or 13.6 cts. per lin. ft. of sewer. The cost of the clam-shell excavator work was as follows:

Item.	Per shift.
1 engineer, at \$6.....	\$ 6.00
1 fireman, at \$3.....	3.00
3 laborers, at \$2.....	6.00
Coal (estimated)	5.00
Oil, repairs, etc.....	2.00
Total	\$22.00

There were 55 shifts worked giving a total cost of \$1,210. In addition the drag bucket excavator was worked backfilling for 18 shifts at \$24.50 making a total of \$441. Lumping the work of both machines, the cost of backfilling was 40.6 cts. per lin. ft. of sewer and 6.8 cts. per cu. yd.

Materials.—The cost of materials was as follows:

Item.	Total.
1,018,000 brick, at \$5 per M.....	\$5,090.00
3,054 bags Utica cement, at 20 cts.....	610.80
3,054 bags Universal cement, at 35 cts....	1,065.90
Lumber (estimated)	600.00
Total	\$7,369.70

This is a cost of \$1.81 per lin. ft. of sewer.

Hauling Materials.—For about 3,000 ft. of the work all materials were hauled from the railway siding in 2 cu. yd. steel dump cars running on narrow gage track. The average haul was 1,700 ft. For the remainder of the work the hauling was done with teams, brick were hauled by subcontract for 70 cts. per M. Two teams were also employed throughout the work to haul supplies from local dealers and to haul coal to the excavators when they were beyond reach of the contractors' railway. The cost of hauling was as follows:

Item.	Total.
Laborers, 767 days, at \$2.....	\$1,534.00
Foreman, 52 days, at \$3.50.....	182.00
Brick, hauled by team at 70 cts. per M..	194.60
Teams, 100 days, at \$5.50.....	550.00
Total	\$2,460.60

The cost of hauling was thus 60.7 cts. per lin. ft. of sewer.

Superintendence and General Expenses.—The costs under these items comprised the following:

Item.	Total.
Superintendent, 2 months, at \$150.....	\$ 300.00
General foreman, 2 months, at \$150....	300.00
Master mechanic, 1 month, at \$200.....	200.00
Clearing right of way.....	80.00
Waterboys, 160 days, at \$1.50.....	240.00
Handy teams, 52 days, at \$3.....	156.00
Total	\$1,226.00

This gives a cost of 30 cts. per lin. ft. of sewer.

Summary.—Summarising the costs of the work per lineal foot of sewer we have:

Item.	Per lin. ft.
Drag bucket excavation.....	\$0.503
Hand excavation	1.250
Pumping	1.610
Sheeting	0.368
Laying sewer	1.320
Backfilling by hand.....	0.136
Backfilling by machine.....	0.406
Materials	1.810
Hauling materials	0.607
Superintendence and general.	0.300
Depreciation of plant, repairs, etc. (estimated)	1.500
Total	\$9.810

Cost of Rock Excavation for Sewer Trenches in St. Louis.—The following data were published in *Engineering-Contracting*, May 30, 1906: The excavation of sewer trenches in South Benton street, Sewer District No. 6, St. Louis, was mostly in solid rock, of a limestone formation usual to the vicinity. The work was done by contract, and the actual cost of the work is given below.

The rock is a limestone lying in horizontal ledges or strata, 1 ft. to 3 ft. thick. The top 4 ft. or 5 ft. of rock is more or less rotten and seamy, easily shot and sledged to pieces. Below this top rock it is hard and difficult to break up.

Dirt seams run through it all, at times causing the ledge to break out back under the sides of the trench, requiring considerably more excavation than is estimated and paid for under the specifications. An estimate of this extra excavation is about 20% more than is paid for. The specifications stated that when solid rock was encountered in laying pipe sewers, the solid rock was to be excavated 6 ins. below the flow line for all pipes of 18 ins. or less in diameter, and 9 ins. below the flow line for pipes of greater diameter than 18 ins. The trench was then to be filled with sufficient earth, well rammed, to form a foundation upon which the pipe should be laid. Payment for the work was made as follows: Class "A," (Earth), Class "B" (Loose Rock), Class "C" (Solid Rock), and quicksand excavation for pipe sewers was paid for at the prices bid for Class "A," Class "B," Class "C" and quicksand excavation, respectively, and was estimated for a width 12 ins. greater than the inside di-

iameter of the pipe, for all pipe 18 in. or less in diameter and 15 in. for pipes of greater inside diameter than 18 in.

To quarry the top rock, the drill holes were staggered, spaced about 4 ft. apart along the trench and about 6 ins. from the sides of the required width of trench. See Fig. 5. In the lower and harder rock, the spacing of drill holes was $2\frac{1}{2}$ ft. but similarly staggered. If any rock projected too far out, it was sledged or shot off by light shots.

To break up a ledge or strata, the drill holes in the top rock were driven about half way through the ledge while for the lower rock they were driven $\frac{3}{4}$ to $\frac{5}{8}$ the thickness of ledge. Hand drills, 1 $\frac{1}{4}$ -in. bit, were used, one man to a drill, and about 10 lin. ft. of hole was drilled per 8 hours' work. The shots were about one stick of 60% dynamite per foot in depth of drill hole.

The costs given here do not include insurance, collection of special tax bills, tools, and office expenses. The blacksmith bill was \$355, or 20 cts. per cu. yd.; the powder bill \$689.76, for about 4,300 lbs. of dynamite; the wages of foremen were \$5.00, quarrymen \$3.00,

Fig. 5. Spacing of Drill Holes.

and a few laborers \$2.00 per 8-hour day. The total amount of rock paid for was 1,683 cu. yds. The cost of dynamite was, therefore, \$0.40 per cu. yd., and amount was $2\frac{1}{4}$ lbs. per cu. yd. On the supposition of 1-5 more rock actually handled than allowed in the estimates, the dynamite is \$0.34 per cu. yd., or 2 lbs. per cu. yd. The average amount of rock for an 8-hour day per quarryman was 0.96 cu. yd.

The following tables are based upon measurements and quantities estimated and paid for under the specifications. The average costs are derived from this estimate and the expense account on the whole or actual excavation.

370 lin. ft., 21-in. sewer; average depth in solid rock, 14 ft.:

Foreman, 67 days, at \$5.....	\$ 335
Quarryman, 700 days, at \$3.....	2,100
Laborer, 73 days, at \$2.....	146

Total, 600 cu. yds., at \$4.30.....\$2,581

287 lin. ft., 18-in. sewer; average depth in solid rock, 13 ft.:

Foreman, 54 days, at \$5.....	\$ 270
Quarryman, 343 days, at \$3.....	1,029
Laborer, 53 days, at \$2.....	106

Total, 317 cu. yds., at \$4.43.....\$1,405

314 lin. ft., 18-in. sewer; average depth in solid rock, 13 ft..

Foreman, 65 days, at \$5.....	\$ 320
Quarryman, 350 days, at \$3.....	1,050
Laborer, 80½ days, at \$2.....	161

Total, 380 cu. yds., at \$4.04.....\$1,536

222 lin. ft., 15-in. sewer; average depth in solid rock, 11 ft.:

Foreman, 36 days, at \$5.....	\$180
Quarryman, 215 days, at \$3.....	645
Laborer, 40 days, at \$2.....	80

Total, 206 cu. yds., at \$4.39.....\$905

251 lin. ft., 15-in. sewer; average depth in solid rock, 8 ft.:

Foreman, 22 days, at \$5.....	\$160
Quarryman, 129 days, at \$3.....	387
Laborer, 60 days, at \$2.....	120

Total, 180 cu. yds., at \$3.70.....\$667

The average cost of the rock excavation was as follows:

	Per cu. yd.
Foreman and labor.....	\$4.20
Dynamite	0.40
Blacksmith	0.20

Total

\$4.80

On the estimate of 1-5 more actually excavated than allowed for the average cost of rock excavation was as follows:

	Per cu. yd.
Foreman and labor.....	\$3.50
Dynamite	0.34
Blacksmith	0.16

Total (actual excavation).....\$4.00

The cost of excavation of earth and loose rock was \$0.50 and \$1.40 per cu. yd., respectively. The cost of backfilling was \$0.15 per cu. yd. of excavation.

For the information in this article we are indebted to Mr. Curtis Hill, Civil Engineer of the Sewer Department, St. Louis, Mo.

Cost of Pipe and Brick Sewers, St. Louis.—Mr. Curtis Hill gives the following data, which are averages of work done by contract during three years, April, 1901, to April, 1904. The work consisted in building 40 miles of vitrified pipe sewers, 12 to 24 ins. diam., and 13 miles of egg-shaped (18 x 27-in. to 48 x 60-in.) and circular (60 to 108-in.) sewers. The egg-shaped sewers were 9 ins. thick; the circular sewers were 13 ins. thick. The excavation was, for the most part, in stiff clay, only a small amount of quicksand occurring. Trench excavators were not very successful, because the "joint clay" caved in if not well braced as fast as excavated. The Chicago Sewer Excavator, however, made the best records made with trench excavators. Potter trench machines were largely used for the smaller trenches, and cableways for the larger trenches. The Potter machine consists of a movable trestle, and a bucket car that rides on tracks on top of the trestle bents. This car is moved back and forth by a stationary hoisting engine, which also hoists the buckets. The legs of the trestle span the trench and are provided with wheels that rest on rails.

The following table gives the actual average cost to the contractors, including foremen and superintendence, but not including interest and depreciation of plant, insurance of men, and office expenses.

COST OF PIPE AND BRICK SEWERS, ST. LOUIS.

Brick Sewers.	Earth Excavation.			Brick Masonry.		
	Cut in feet to sub-grade.	Cu. yds. per la- borer per hour	Cost per cu. yd.	Cu. yd. per ma- son per hour.	Cost of labor and mason per cu. yd.	Cost of materi- al per cu. yd.
12½' x 15'.....	30	1.18	\$1.71	\$6.13
9' circular†.....	26	1.0	\$0.36	1.40	1.87	6.13
6' circular†.....	17	0.8	0.40	0.97	1.75	6.30
5' circular†.....	16	0.8	0.40	0.95	1.80	6.30
2' x 3'‡.....	11	0.80	2.40	6.10
						Total cost per cu. yd.
						\$7.84
						8.00
						8.05
						8.10
						8.50

* Method of excavation was steam shovel followed by a cable-way. The lumber bracing cost \$3.60 per running foot of sewer.

† Potter trench machine used.

‡ No trench machine used.

The "cu. yds. per laborer per hr." means the number of cubic yards excavated and loaded into buckets by each laborer actually engaged in digging. The average of all the work, including pipe sewers, was about 9 cu. yds. excavated per man per 10-hr. day.

On pipe sewer trenches, where no machinery was used, the cost of earth excavating was as follows:

Size of pipe, ins.	Depth in ft.	Cost per cu. yd.
24	15	\$0.50
21	16	0.50
21	7	0.36
18	8	0.35
15	16	0.55

It cost 90 cts. per cu. yd. to excavate loose rock in the trenches 15 and 16 ft. deep; and \$3.80 per cu. yd. to excavate solid rock.

Four men, the bottomman and his helper, with two men handling and lowering the pipe, laid 21-in. and 24-in. pipe at the rate of sixteen lineal feet per hour, at a cost of 6 cts. per lin. ft. Three men will lay the same amount of 15-in. or 18-in. pipe in the same time. Including the material for jointing, the cost of laying pipe is 10 cts. per lin. ft.

"A good sewer brick mason will lay from 400 to 500 bricks per hr. There is one case where four masons, working on a 6½-ft. brick sewer, each averaged 600 bricks per hr., and kept it up for several days, but this is far above the average."

The average contract prices for the three years (1901-4) was as follows:

12-in. pipe, per lineal foot.....	\$ 0.45
15-in. pipe, per lineal foot.....	0.55
18-in. pipe, per lineal foot.....	0.80
21-in. pipe, per lineal foot.....	1.00
24-in. pipe, per lineal foot.....	1.60

Pipe junctions, extra, each.....	1.50
Slants for brick sewers, each.....	0.65
Earth excavation, per cubic yard.....	0.55
Loose rock excavation, per cubic yard.....	1.60
Solid rock excavation, per cubic yard.....	4.00
Concrete, per cubic yard.....	6.50
Brick masonry, per cubic yard.....	9.40
Vitrified brick masonry, per cubic yard.....	12.20

It will be noted that the excavation was paid for as a separate item, and not included with the pipe or brick.

Mr. Hill informs me that on a recently completed brick sewer, requiring 287 days to build, two Potter machines and a cableway were used. There were 49,918 cu. yds. of Class "A" excavation (earth), 6,629 cu. yds. of Class "B" (loose rock), and 33 cu. yds. of Class "C" (solid rock). There were 2,303 lin. ft. of 9-ft. sewer, 3,240 lin. ft. of 8-ft. sewer, 254 lin. ft. of 7-ft. sewer, 1,607 lin. ft. of 5½-ft. sewer, and 1,203 lin. ft. of 4 x 5-ft. sewer. These required 8,177 cu. yds. of hard brick masonry and 723 cu. yds. of vitrified brick masonry. The excavation ("A," "B" and "C") cost 68 cts. per cu. yd., of which 11½ cts. was the cost of the trench machines. The total cost of this trench excavation (56,580 cu. yds.), including labor of bracing and backfilling, was as follows:

Foreman, 6,400 hours, at 50 cts.....	\$ 3,200.00
Laborer, 87,000 hours, at 22½ cts.....	19,575.00
Bottom-man (pipe layer), 6,360 hours, at 30 cts.....	1,908.00
Waterboy, 3,800 hours, at 15 cts.....	570.00
Team, 10,450 hours, at 50 cts.....	5,225.00
Watchman, 4,800 hours, at 25 cts.....	1,200.00
Machine, 4,400 hours, at \$1.50.....	6,600.00

Total, 56,580 cu. yds., at \$0.68.....\$38,278.00

Most of the trenches require bracing, the timber for which costs 2 cts. to 10 cts. per cu. yd. of excavation, which is not included in the above. Yellow pine costs \$18 per M.

The wages of foremen, waterboys and watchmen are all charged against excavation, and no part against masonry.

The cost of laying the brick masonry was as follows:

Masons, 9,400 hrs., at 75 cts.....	\$ 7,050.00
Helpers, 1,400 hrs., at 25 cts.....	3,500.00
Mortarmen, 10,750 hrs., at 27½ cts.....	2,956.25

Total for 8,900 cu. yds., at \$1.53....\$13,506.25

The masons averaged 422 bricks per hr., or 3,376 bricks per 8-hr. day.

Cost of a Brick Sewer at St. Louis, Including Tunneling in Earth and in Rock.—The following data were published in *Engineering-Contracting*, July 10, 1907.

The 13th street sewer in St. Louis, Mo., was designed to give deep drainage in a down town district, where the street is narrow, the traffic heavy, and the ground well filled with pipes and conduits. Owing to these conditions, the plans were made and contract let for tunneling the entire sewer. The sewer is brick, 30-in. x 42-in. diameter and 1,458 ft. in length.

Taking a mean length of earth and rock, there were 630 ft. of earth and 828 ft. of solid rock tunnel. Five shafts were used in the earth section and ten in the rock.

The work was done by the Myers Construction Co. of St. Louis during the winter of 1906-1907, in 190 days, including Sundays and holidays.

The contract included the excavation of 1,156 cu. yds. of earth

* A trench machine is rented for \$125 per month, and burns 16 bushels of coal per 9-hour day. When the rental and fuel costs are added to the wages of engineman and fireman, the total cost is \$1.50 per hour.

and 880 cu. yds. of rock, and the construction of 770 cu. yds. of brick masonry. The work was paid for on the unit basis and all work done was measured up and paid for.

The earth was a plastic clay, which would drop out in the arch following the shovel. In this way extra work over the arch (over and above the regular 9-in. brick work) averaged 3 ins. In the

rock tunnel, the average was 7 ins. over the arch and 6 ins. on the lower quarter haunches of the invert. These spaces were filled solid with brick masonry.

In the earth section, a small opening was driven 4 ft. to 6 ft. in length, and braced with a crown plank and short upright supports. As this was enlarged, other crown planks were inserted, replacing the shorter supports with longer ones. The masonry was then built in the section, removing the timber supports as the masonry progressed. Material for the next section was passed through the finished one.

The rock was a stratified limestone, irregular and gnarly. It varied in hardness, in some places to a flinty appearance. The blasting was done in batteries of three shots, the first in the upper, or arch, portion of the heading. When this broken rock had been removed, the same process was repeated on the lower, or invert, section. Holes were driven to a depth of about 2 ft. and loaded with from $\frac{3}{4}$ to $1\frac{1}{4}$ sticks of 50 per cent dynamite, the size of stick depending upon the indicated hardness and position of the rock.

The cost of the work was as follows:

Earth excavation:	Per cu. yd.
Foreman, 620 hrs., at \$0.50.....	\$0.225
Bottommen, 1,320 hrs., at \$0.50.....	.571
Laborers, 7,500 hrs., at \$0.30.....	1.946
Carpenter, 830 hrs., at \$0.50.....	.359
Labor, timbering, 620 hrs., at \$0.30.....	.161
Timber, 22 M ft., at \$20.....	.381
Watchman, 520 hrs., at \$.017½.....	.079
Waste, 585 loads, at \$1.....	.506
Total	\$4.228

The earth excavation amounted to 1,156 cu. yds. and each laborer averaged .164 cu. yd. per hour.

Rock excavation:	Per cu. yd.
Foreman, 1,000 hrs., at \$0.50.....	\$0.568
Bottommen, 2,600 hrs., at \$0.50.....	1.477
Laborers, 9,980 hrs., at \$0.30.....	3.403
Engineer, 1,600 hrs., at \$0.50.....	.909
Blacksmith070
Watchman, 1,600 hrs., at \$.017½.....	.318
Dynamite, 4,000 lbs., at \$0.15.....	.682
Caps and fuse.....	.030
Waste, 445 loads, at \$1.....	.500
Total	\$7.956

The rock excavation amounted to 880 cu. yds. and each laborer averaged .088 cu. yd. per hour. In the figures given above for earth excavation and rock excavation, by the item "waste" is meant the excavated material that it was necessary to take away, in other

words the surplus excavation. The length of the haul was about $2\frac{1}{4}$ miles, and, where the contractor hired teams for the purpose, they were paid by the load at the rate of \$1 per load. The figures given for "waste" are what the contractor actually hired teams to remove; but, in addition, he used some of his own teams, of which he kept no close record.

Brick masonry:	Per cu. yd.
Bricklayer, 1,180 hrs., at \$1.....	\$1.532
Helpers, 2,400 hrs., at \$0.30.....	.936
Watchman, 480 hrs., at \$0.17½.....	.109
Brick, 340 M., at \$9.....	3.974
Cement, 460 bbls., at \$1.80.....	1.075
Sand, 190 cu. yds., at \$1.....	.247
Total	\$7.872

A total of 770 cu. yds. of brick work were constructed; of this amount 78 cu. yds. were constructed of vitrified brick, costing \$12.00 per M. Allowing for the extra cost of this vitrified brick brings the total cost of the brick masonry per cubic yard to \$7.99. The vitrified brick masonry alone cost \$8.12 per cu. yd. Each bricklayer averaged .652 cu. yd. per hour.

The plant used in the work and its cost were as follows:

Dynamo, 20 hp., and electricity for 4 months.....	\$800
Compressor	250
Receiver	25
Air drills (Ingersoll-Rand, N. Y.), 8, at \$110....	230
Pumps, two 2-in. at \$60, and one 1-in. at \$20....	150
Hand windlasses	100
Tools, boots, lights, gasoline, etc.....	200

With the exception of the last two items, all of the plant was used in rock excavation alone. The earth section of the tunnel was worked from the outlet and there was little pumping required.

In the costs given above no charge has been made for plant, nor do the costs include office expenses of the contractor nor insurance of the men. For the information from which this article was prepared we are indebted to Mr. Curtis Hill, C. E., of St. Louis, Mo.

Cost of Pipe and Brick Sewers and Manholes in St. Louis.—This sewer, which was known as the Tam Avenue public sewer, was constructed in St. Louis, Mo., and consisted of 262.5 ft. of 24-in. pipe sewer and 154 ft. of 22-in. x 33-in. brick sewer and one manhole.

The brick portion of this sewer is under the Missouri Pacific Railroad tracks and the street railway tracks on the adjoining street. The tracks consist of five railroad and two street car tracks. The work here was done in open cut, the railway companies supporting their own tracks. The difficulty of working through and under these tracks somewhat increased the cost of the

brick sewer. Even with this, the cost of rock excavation is low, since the rock belonged to a class easily handled, being horizontally stratified limestone, more or less rotten on top, while the rest shattered well when blasted.

The drill holes were vertical (drilled with hand, or churn drills), spaced about 3 ft. along the center of the trench, driven about $2\frac{1}{2}$ ft. deep and loaded with $1\frac{1}{2}$ sticks, about 1 lb.) of 40% dynamite. The driller held his own drill, one man drilling, i. e., only one drill with one man to a hole. Limestone was ordinarily found in one to three foot strata, and the drill holes were driven to such a depth that the shot would tear out the strata. The layers of stone were of a depth at this place that holes about $1\frac{1}{2}$ ft. deep loosened up the stone to the layer beneath. The top 4 or 5 ft. (and sometimes more) of the rock were rotten, and all that was necessary in the way of blasting was to loosen up the ledge, then sledge and pick it out. The shots were in the center of the trench, which would

Fig. 6. Profile of Tam Avenue Sewer.

leave the sides of the trench ragged, but the same rotten rock can be sledged and dressed off to required width.

The trench was $3\frac{1}{2}$ ft. wide. The width of rock excavation paid for is estimated to the extreme width of the brick work down to sub-grade. The railroad ballast is included in the earth excavation. All excavation costs include the labor of backfilling, disposal of surplus, bracing, etc., but no allowance is made for lumber for bracing, nor for the incidentals, such as care of tools, insurance, contractor's office expense, etc. No machinery was used.

Cement, 2.5 bbls., at \$1.50	3.75	.94
Sand, 1 cu. yd., at \$1.00	1.00	.25
Total	\$34.00	\$9.48
Cast-iron (head), 490 lbs., at \$0.02½	12.25	
Wrought-iron bands and steps, 102 lbs., at \$0.04	4.08	
Total cost of manhole	\$50.33	

The information given above was furnished by Mr. Curtis Hill, Chief Engineer of the Sewer Department of St. Louis, Mo., and published in *Engineering-Contracting*, March, 1906.

Cost of a Brick Sewer at Syracuse, Built by Tunneling.—The following data were published in *Engineering-Contracting*, Nov. 14, 1906.

The so-called tunnel line sewer of Syracuse, N. Y., was constructed for the purpose of draining some 600 acres of land. The area to be drained lies in a valley, surrounded entirely by a ridge of hills, so that the excavation for the sewer had to be done partly by the open cut method and partly by the tunnel method. The cost figures that follow are for a section of the sewer constructed by the latter method. The sewer has a total length of 4,717 ft. and, starting at Grumbach avenue (see Fig. 7), the first section of 470 ft. was constructed by the open cut method; then came 1,135 ft. of tunnel, 495 ft. of open cut, 670 ft. of tunnel, 1,240 ft. of open cut, 280 ft. of tunnel, and finally 431 ft. of open cut. The sewer is circular, 33 in. inside diameter, constructed of two rings of brick laid in cement mortar, and was designed to flow one-half full. As originally planned it was proposed to have cuts under 30 ft. made by the open cut method; the contractor, however, decided to build the sewer for the distance of 495 ft. between the two longest tunnels in tunnel construction. All tunnel openings are permanent, manholes being built at these points, and also at places where the tunnel line intersects streets, a distance of about 600 ft. apart.

Open Cut Method.—Work on the first open cut section of the sewer was commenced at Grumbach avenue on Dec. 2, 1905. The cut ran from 13 ft. at Station 0 to 32 ft. to sub-grade at the first section of the tunnel (Station 4 + 70). The first 6 ft. of the cut was cast out by hand, but from this point to sub-grade a trenching machine was used to handle the material. The first material encountered was 7 ft. of loam clay and gravel, and underlying this was a stiff red clay containing stone and gravel, varying in size from pebbles to 12-in. boulders.

The trenching machine was built by the contractor. It consists of a bucket car mounted on wheels, and had a device at the top for use in hoisting the buckets. The latter were of iron, revolving type.

Fig. 7. Profile of Tunnel for Sewer.

$\frac{3}{4}$ cu. yd. capacity, of the kind ordinarily used on trenching machines. The car ran on a track extending over the trench, spiked to cross ties laid on the ground, the rails being laid so that the car cleared the line of sheeting. A double drum stationary engine in an engine house, mounted on wheels, was used to operate the car and the hoisting apparatus. One drum of the engine was attached to the cable for moving the car; the other drum operates the cable for raising and lowering the buckets. The cable runs from the engine house to an A frame, and a working distance of 200 ft. can be made advantageously.

The operator, standing on the car in view of the trench and buckets, gave the signals to the engineer to raise or lower the buckets or to move the car forward or backward on the track. Buckets were distributed along the trench and when filled the operator dropped an empty one, picked up a filled bucket and carried it backward, dumping the material over the completed sewer. In this way the completed sewer was backfilled as rapidly as the work was finished. When it was necessary to move the machine ahead, rails were laid and the engine house moved forward under its own power, carrying the A frame along with it.

By Jan. 4, 404 ft. of the first 470 ft. of open cut sewer had been completed, the remaining distance being left open to allow the engineers distance for a backsight to project the line into the tunnel. This section was afterwards built to within a few feet of the tunnel opening, only enough room being allowed in which to raise and lower the buckets.

The sewer constructed in the open cut excavation was circular, 23 ins. in diameter, the invert being of second quality paving brick and the arch of ordinary sewer brick. The brickwork was laid on a cradle of 1-in. hemlock nailed to 2-in. square forms, the cradle being backed with concrete for 3 ins. underneath and 6 ins. at the spring line. The space below the spring line was also filled with concrete.

Tunnel Method—Work on the tunnel section was first commenced at the western end (Station 4+70). It was planned originally, however, to start the shaft at Oak street and the shaft at De Witt street about the same time that the open cut excavation was commenced, and in this way start the tunnel excavation simultaneously in four headings. Later on the work was carried on in four headings.

The dimensions of the tunnel excavation were 7 ft. 9 ins. x 5 ft. 10 ins., and the materials encountered were a clay rock and in some instances slate rock. In the first section small pockets of clay and sand were encountered, which necessitated very close side sheeting. All of the drilling was done by hand, four holes, spaced about a foot from the side, being drilled in the face. The two upper holes were drilled about 13 ins. from the roof, the lower ones being from 18 ins. to 2 ft. from the floor. At first each hole was loaded with one stick of 40% dynamite, and all four holes blown at once. This threw down the whole face and was very effective. It was found, however, that the charge was too heavy for the tim-

bering to stand safely, and accordingly the two upper holes were loaded with $1\frac{1}{2}$ sticks of dynamite and fired. After the muck had been cleared away the two lower holes were loaded with the same sized charge and fired. The result proved satisfactory. The holes were drilled from 2 ft. to $2\frac{1}{2}$ ft., and the face thrown out by the blast had a depth of 18 ins. to 2 ft. Before a blast was fired a platform was laid at the foot of the face, and the material or muck was blasted out upon it. In this way the material was more easily handled.

The method of timbering the tunnel is shown in Fig. 8. All timber used in the tunnel was beech, which on account of its toughness did not splinter or brush. The timber consisted of 6-in. x 6-in. frames, spaced about 5 ft. centers. The cap and sill were $5\frac{1}{2}$ ft. long and uprights were $6\frac{1}{2}$ ft. long, with corners temporarily strapped with angle iron, which was withdrawn after overhead

Fig. 8. Sewer in a Tunnel.

and sidebridging had advanced two frames. On top of the frames at each corner were blocks, on which was placed 2-in. plank, leaving a space for driving overhead sheeting. On account of this overhead sheeting causing a pressure on the plank placed on the blocks, the edge of the plank was beveled and the overhead sheeting pointed to allow it to enter the space.

The excavated matter was removed in buckets, similar to those described under open cut work. These buckets were placed on a platform car which ran on a 2-ft. gage track carried along as the tunnel progressed. The car was pushed to the mouth of the tunnel by one of the men, where it was raised by trenching machine previously described, and conveyed to the dumping ground. The excess of material was used in filling low land near the tunnel opening, the haul consequently being very short. The platform car was also used in carrying lumber and other materials into the tunnel, and in carrying out boulders, etc.

The foul air caused by the dynamite fumes, also from working so far in the tunnel without ventilation, was overcome by pumping fresh air into the tunnel through a 3-in. galvanized pipe by means of a rotary steam fan. In this manner the air was kept very pure, and within a short time after a blast was fired the fumes had passed away and the workmen were able to return to the breast of the heading to clear away the muck.

Some water was encountered, and this was pumped from the tunnel at the low points, as Station 4+70 and shaft at Oak street, by means of a steam siphon into the completed sewer. At the DeWitt street shaft the water was pumped out by a pulsometer, and in this way the tunnel was kept comparatively dry. In the section of the tunnel from Oak street to DeWitt street a very hard clay rock, bearing gypsum, was encountered, which proved not only hard to drill, but could not be blasted out satisfactorily. In addition water ran continually from the breast of the heading and also from the sides of the tunnel, making constant pumping necessary. The drillers were obliged to wear rubber suits. The rate of progress was about one-half as great as in the section from 4+70 to Oak street.

Cost Data on Tunnel Sewer Construction.—Cost data on the construction of a greater portion of the first section of the sewer built by the tunnel method are given below. These costs are for a total length of sewer of 1,047 ft., that is, for the sewer starting at Station 4+70 to within about 100 ft. of DeWitt street (see Fig. 7). In these data the cost of drilling per foot of hole could not well be separated from picking and shoveling into buckets, as some men worked on both. The drilling was all done by hand, and after a shot was fired the drillers shoveled the muck and trimmed up with picks. Water was, in general, taken care of with a steam siphon at one shaft and pulsometer at other. Hand balling was occasionally resorted to.

From Jan. 15 to Feb. 22, in 35 days of actual work, 173 lin. ft. of tunnel was excavated, or an average of 4.94 ft. per day of ten hours. The allowed excavation was 45.18 cu. ft. per lineal foot of tunnel; consequently an average of 8.26 cu. yds. was excavated each day. The material was hard red clay, which worked well. The work was done by one gang working ten hours per day. The labor cost per day was as follows:

	Per day.	Total.	Per lin. ft.
6 men in tunnel	\$2.00	\$12.00	\$2.42
1 shooter	3.00	3.00	.60
1 foreman	2.50	2.50	.50
1 engineer	1.75	1.75	.35
4 men on top	1.75	7.00	1.42
1 waterboy	1.00	1.00	.20
Total		\$27.25	\$5.50

From Feb. 22 to March 23, three shifts of eight hours each per day were worked by the men in the tunnel. The actual number of days worked was 20, and in this time 115 lin. ft. of tunnel was excavated, an average of 5.75 lin. ft. per 24 hours, or 1.23 lin. ft.

per 8-hr. shift. The material was clay rock with from 12 ins. to 20 ins. of gypsum in the bottom. This material was very hard and progress was consequently slow. The labor cost per day was as follows:

	Per shift.	Per day.	Per lin. ft.
8 men in tunnel.....	\$2.00	\$36.00	\$9.40
1 sheeter	3.00	6.00	1.57
2 men on top	1.75	7.00	1.82
1 engineer	1.75	3.50	0.91
1 waterboy	1.00	2.00	0.52
Total		\$54.50	\$14.22

The 6 men in the tunnel worked an 8-hr. shift; all others worked 12 hours.

From March 23 to April 4, two headings were worked, the men in the tunnel working in three shifts of eight hours each. The actual number of days worked was 13, and in this time the tunnel was advanced 216 ft., or 8.31 ft. per heading per 24 hours. At the shaft heading at Oak street the material was a soft clay rock which worked easily. In the west heading the gypsum continued until March 14, when it disappeared entirely.

The labor cost per day was as follows:

	Per shift.	Total per day.	Per lin. ft.
12 men in tunnel.....	\$2.00	\$72.00	\$4.33
2 sheeters	2.00	12.00	0.72
6 men on top	1.75	21.00	1.26
2 engineers	1.75	7.00	0.43
1 team	4.00	8.00	0.43
1 tag line boy.....	1.25	2.50	0.15
Total		\$123.50	\$7.36

The materials used in the work from Jan. 15 to April 4, when the first section of the tunnel was completed, were as follows:

	Rate.	Total.	Per lin. ft.
3,255 lbs. dynamite.....	\$0.14	\$315.70	\$0.63
32 tons coal	3.50	112.00	.23
110 gals. olive oil.....	.45	49.50	.10
50 gals. engine oil34½	17.25	.03
860 electrical exploders...	.03½	30.10	.06
55,000 ft. B. M. lumber.....	16.00	880.00	1.74
Total		\$1,404.55	\$2.78

The total cost of the tunnel work from Jan. 15 to April 4, a total progress of 504 ft. having been made, was as follows:

	Per day.	Total.
Labor, 25 days.....	\$ 27.25	\$ 681.25
Labor, 30 days.....	54.50	1,635.00
Labor, 13 days.....	123.50	1,592.50
Total		\$4,081.25
Blacksmith, 150 hrs., at 25 cts.....		39.00
Materials		1,405.55
Repairs		100.00

Grand total, 504 ft., at \$11.16..... \$5,624.80

Part of blacksmith work, sharpening picks, etc., was done by one

of the men on top and is not separated from cost of labor of men on top. Men on top also made wedges and assisted the sheeter in cutting frames, etc. One man on top acted as conductor on the bucket car.

The above costs include not only the excavation, but also the sheeting of the tunnel, and in addition a small amount of concrete work. The cost of sheeting the tunnel was approximately as follows:

	Total	Per lin. ft.
Labor	\$ 546	\$1.08
Timber	880	1.74
Total	\$1,426	\$2.82

The labor cost on concrete amounted to about \$110; deducting this and the cost of sheeting from the total cost (\$5,624.80), we have \$4,088.80 as the cost of excavating the tunnel. The average cost per lineal foot of excavation would then be \$8.11. At the allowed excavation, 45.18 cu. ft. per lineal foot, the average cost of excavation per cubic yard for the 504 ft. was \$4.87. The labor referred to in the foregoing tables as "men on top" included man tending dump, conductor on bucket car, cutting wedges and all incidental work.

Brickwork in First Section of Tunnel.—The sewer construction in the tunnel is the same as in the open cut, or 33-in. circular, 2-ring brick, laid on a cradle. The allowed thickness was 9 ins. or 8.25 cu. ft. per foot of sewer. All space below the spring line is filled with second-class natural cement, mixed in a 1:3:7 proportion. From the spring line of the sewer to the roof tunnel the space is backfilled with carefully rammed earth. The brickwork was carried 4 ft. from the opening of the tunnel, making 500 ft. of completed sewer for the first section.

The brickwork, backfilling, etc., for the 500 ft. of sewer were completed in 18 days of 12 hours each, the cost being as follows:

	Rate.	Total.	Per lin. ft.
1 mason	\$4.50	\$ 4.50	\$0.16
1 mason	3.00	3.00	.11
5 men	2.00	10.00	.36
Total		\$17.50	\$0.64

The materials used were as follows:

	Rate.	Total.	Per lin. ft.
75,000 brick	\$7.50	\$ 562.50	\$1.12
115 bbls. cement.....	1.20	138.00	.27
105 cu. yds. gravel.....	1.25	131.25	.26
Total		\$ 831.75	\$1.66
18 days labor, at \$17.50.....		315.00	.64
Grand total		\$1,146.75	\$2.30

The above work included 153 cu. yds. of brickwork, 110 cu. yds. of concrete and 310 cu. yds. of backfilling. The latter was done by the men who assisted the bricklayers, each 5-ft. section taking four men about 1½ hours. The labor cost of the backfilling was \$112.40. The labor on concrete consisted of about 550 hours' work

at 20 cts. per hour, or \$110. Deducting these amounts from the total of \$1,146.75, we get \$222.25 as the cost of the brickwork for the first section of sewer.

On this basis the cost per lineal foot was \$1.25, and the cost per cubic yard of brickwork was \$6.03.

The cost of the forms or cradles used in construction of brickwork could not be separated from lumber cost. The cost was very small.

Shaft at Oak Street—The dimensions of the shaft at Oak street were 10 ft. x 16 ft. on top; the bottom measured 9 ft. x 15 ft. The shaft was sunk to a depth of 58 ft. The materials encountered followed very closely those shown by the test borings as shown in Fig. 7. The shaft was divided into three compartments, the middle compartment, used for hoisting buckets, being 6 ft. in clear and the end compartments being 3½ ft. in clear. One end compartment was used for a ladderway, the other end compartment being used for a pumpway. Beech timber was used and sets or frames were all 6-in. x 8-in. timber; the sidewalls were 16 ft. long, braces 6½ ft. long. The lagging was 2-in. beech. All of the drilling on shafts and tunnel was done by hand.

A machine was used at this shaft for hoisting and disposing of excavated matter from the tunnel. It consisted of a platform car, 12 ft. long by 8 ft. wide, mounted on standard gage steel trucks. Buckets were hoisted through a hole 4 ft. 10 ins. by 6 ft. in the platform. Over this hole was an iron angle frame, at the top of which was the hoisting device for raising and lowering the buckets. The mechanism is similar to that of the trenching machine, previously described. A 4-cylinder, 4-cycle gasoline engine of 20 hp. furnished the power to operate the hoisting apparatus and to move the car. The engine acts through a two-way friction clutch; one way throws in a single drum and operates the cable which hoists or lowers the buckets; the other way throws gears connected to a sprocket on the car wheel, causing the car to move forward or backward, the direction being controlled by a marine reversing device. The bucket operator stands between the bucket opening and one end of the car. The engine and drum are at the other end of the car and the engineer is stationed near the opening, where he can operate levers and at the same time have a clear view of the shaft below. The machine was designed and built by the contractor for the work.

In sinking the shaft, red clay was encountered to within 15 ft. of the bottom, when some boulders were reached, and in the bottom was 3 ft. of clay rock. The shaft was sunk in 14 days of 10 hours each, the cost being as follows:

	Labor.		
	Rate.	Total.	Per lin ft.
7 men in shaft	\$2.00	\$14.00	\$2.33
4 men on top	1.75	7.00	1.69
3 teams	4.00	8.00	1.33
1 engineer	1.75	1.75	.43
1 tag line boy.....	1.25	1.25	.30
Total		\$22.00	\$7.73

<i>Material.</i>			
	<i>Rate.</i>	<i>Total.</i>	<i>Per lin. ft.</i>
250 lbs. dynamite.....	\$0.14	\$35.00	\$0.60
100 electrical exploders.....	3.50	2.50	.08
4 tons coal	3.50	14.00	.24
Total		\$52.50	\$0.90
<i>Summary.</i>			
	<i>Rate.</i>	<i>Total.</i>	<i>Per lin. ft.</i>
Material		\$52.50	\$0.90
30 hrs. blacksmith.....	\$0.25	7.50	.13
14 days, labor.....	32.00	448.00	7.72
12,500 ft. B. M. lumber.....	16.00	208.80	5.32
Total, 58 ft., at \$14.07.....		\$816.80	\$14.07

The manhole in the Oak street shaft was 5 ft. inside diameter with a 1-ft. wall of brickwork to within 20 ft. of the surface, where it was reduced to a 2-in. wall, and 5 ft. from the surface was drawn in from 5 ft. diameter to 2 ft. to allow for an iron cover. Around the sewer the size of the manhole and as far up as the springline was solid brickwork to insure a solid foundation for the manhole.

First-class Portland cement concrete was used as backfilling around the manhole for the full dimensions of the shaft from the springline of the sewer to the top of the normal tunnel excavation; from this point to the surface the backfilling in the shaft was earth. The timbering in both shaft and tunnel was allowed to remain in place permanently.

The cost, including labor on brickwork, backfilling, tending masons and all incidental work, was as follows:

<i>Labor.</i>			
	<i>Rate.</i>	<i>Total.</i>	
1 mason	\$4.50	\$ 4.50	
1 mason	3.00	3.00	
5 men	1.75	8.75	
Per day of ten hours.....		\$16.25	
	<i>Rate.</i>	<i>Total.</i>	
6 men	\$1.75	\$8.75	
	<i>Rate.</i>	<i>Total.</i>	
4 2/5 days	\$16.25	\$71.50	
1 1/2 days	8.75	13.13	
Total labor		\$84.63	
<i>Material.</i>			
	<i>Rate.</i>	<i>Total.</i>	
12,500 brick	\$ 7.50	\$146.25

1 iron cover	10.00	10.00	
24 bbls. cement	1.70	40.80	
19 cu. yds. gravel.....	1.25	23.75	
Total material		\$226.40	
<i>Summary.</i>			
Labor		\$ 84.63	
Material		226.40	
Total		\$311.03	

The measured work complete was 37 cu. yds. brickwork, 10 cu. yds. concrete, 65 cu. yds. backfilling.

Shaft at De Witt Street.—The dimensions of the shaft at De Witt street were 9 ft. by 16 ft. The shaft was sunk to a depth of 36½ ft., through red clay mixed with a few boulders, and 4 ft. of clay rock at the bottom. The shaft was sunk in seven days of ten hours each, the cost being as follows:

<i>Labor.</i>			
	<i>Rate.</i>	<i>Total.</i>	<i>Per lin. ft.</i>
6 men in shaft.....	\$2.00	\$12.00	\$2.81
2 men on top.....	1.75	3.50	.67

		<hr/>	<hr/>
Total, 36½ ft., at \$9.35.....		\$341.45	\$9.35

Cost Data on Second Section of Tunnel.—The second section of the tunnel, from Oak street to De Witt street, 543 ft., was driven in 139 days' labor of 24 hours each. The average progress was about 3.9 ft. per day, or 1.3 ft. per shift of eight hours.

The material from entrance (Station 9 + 88) to Station 10 + 12 was clay rock, which broke up easily, but from this point to Station 15 the material was a hard clay rock bearing gypsum, much of which was of a flinty nature and very difficult to handle. Another disagreeable feature of this section was the large amount of water encountered, which was continuous from Station 10 + 50 to Station 15. Men were obliged to wear rubber suits and pumping and bailing were constantly necessary.

The cost of the work was as follows:

<i>Labor.</i>			
	<i>Per shift.</i>	<i>Per day.</i>	<i>Per lin. ft.</i>
4 men in tunnel.....	\$2.00	\$24.00	\$6.16
1 sheeter	3.00	6.00	1.54
3 men on top.....	1.75	10.50	2.69
1 engineer	1.75	3.50	.90
		<hr/>	<hr/>
Total		\$44.00	\$11.28

Labor (Continued).

129 days	\$44.00	\$6,116.00	\$11.28
77 days extra men halling..	2.00	154.00	.28
62 days blacksmith.....	1.75	108.50	.20
62 days waterboy	1.00	62.00	.11
Grand total for labor.....		\$6,440.50	\$11.87

Materials.

	Rate.	Total.	Per lin. ft.
400 lbs. dynamite	\$ 0.14	\$ 56.00	\$0.10
945 lbs. dynamite	12.00	113.40	.21
843 exploders	3.50	29.50	.05
280 gals. olive oil.....	45	126.00	.23
51 gals. engine oil (bbl.)..	.34½	17.60	.03
35 tons coal.	3.50	122.50	.22
		\$466.00	\$0.84
37,400 ft. B. M. lumber.....	\$16.00	\$598.40	\$1.10

Summary.

	Total.	Per lin. ft.
Labor	\$6,440.50	\$11.87
Material	466.00	.84
Lumber	598.40	1.10
Total, 543 ft. of tunnel at \$13.82..	\$7,504.90	\$13.81

As in the case of the first section the above figures include the cost of sheeting and a small amount of concrete.

The cost of the material for the sheeting was \$598.40, and the labor cost was approximately as follows:

695 hours, at 25 cts.....	\$173.75
1,300 hours, at 17½ cts.....	243.25
Total	\$417.00

	Total	Per lin. ft.
Lumber	\$ 598.40	\$1.10
Labor	417.00	.77
Total	\$1,015.40	\$1.87

The cost of the labor on concrete was approximately \$149.50; deducting this sum and the cost of sheeting from the total of \$7,504.90, and we get \$6,340 as the cost of excavating the second section of the sewer. As the second section of the tunnel was 543 ft. long, the actual average cost per lineal foot was \$11.67; the average cost per cubic yard of excavation was \$7.00.

Cost of Third Section of Tunnel.

Section 3 of the tunnel, from Station 15+45.50 to 21+50, or 605 ft., was driven in 95 days of 24 hours each, or 8.36 ft. per 24 hours. Work on Section 3 began on Aug. 22, with gang working east. On Oct. 8, another shaft was opened and gang started west from shaft No. 3. The two headings met on Nov. 2. The laborers in tunnel, and sheeters, worked in 8-hr. shifts, and engineers and men on top were on duty 12 hours. The material was clay rock, not hard, and therefore easily handled. In this section the engi-

neer attended to blacksmithing, so there was no charge against this item.

Labor Cost.

	Rate.	Total.	Per lin. ft.
855 days, labor in tunnel.....	\$2.00	\$1,710.00	\$2.84
285 days, sheetmen in tunnel....	3.00	855.00	1.41
190 days, engineers.....	2.00	380.00	.63
285 days, labor on top.....	1.75	495.75	.82

Total \$3,440.75 \$5.70

From allowed excavation, the cost is \$2.41 per cu. yd.

110 yds. sand	1.10	121.00	.20
180 bbls. cement98	176.40	.29

Total \$987.40 \$1.61

Grand total \$1,568.46 \$2.56

The labor on top under "setting cradles and placing concrete" was for lowering cradles, mixing concrete and lowering same.

The labor on top under "brickwork" was for lowering brick and mixing and lowering mortar.

The work is being done by contract under the direction of Henry B. Brewster, Assistant City Engineer, to whom we are indebted for the above information.

Cost of a Sewer Tunnel at Chicago, Using a Hydraulic Shield.—The following data were published in *Engineering-Contracting*, Feb. 6, 1907.

The Lawrence avenue conduit of the new intercepting sewer system of Chicago, Ill., is tunnel work through clay. The completed conduit will be 14 ft. inside diameter, lined with 162 ins. of brickwork in four rings, backed by a ring of solid timbering 8 ins. thick. The bore being made by the shields is, thus, 20 ft. in diameter. From Lake Michigan to the Chicago River the conduit is 8,225 ft. long and there is, in addition, an intake tunnel for flushing water extending out under the lake. This article refers only to the land portion of the conduit, which is being built by M. H. McGovern, Contractor, at a contract price of \$79.50 per lineal foot.

The conduit is being constructed by driving two shields in opposite directions from a central shaft, about the top of which are located the contractor's power house, shops, sawmill, storage yards and the spoil bank. The shield work is unusual in the fact that a close lining of timber segments is used to keep the clay in place and to take the thrust of the jacks used to advance the shields. This timbering is described fully in a succeeding paragraph, but it is important to note here that it serves its purpose admirably, being neither crushed nor distorted by the pressure of the jacks.

Shield Construction and Operation.—Fig. 9 is a diagram longitudinal section of the shield and tunnel lining and Fig. 10 is an enlarged detail of the cutting edge of the shield. The structural features and the principal dimensions of the shields are given clearly by these illustrations. Each shield is operated by 24 hydraulic jacks of 80 tons capacity and good for 8,000 lbs. pressure. These jacks are of the Watson-Stillman type with 8-in. barrels and 5.75-in. plungers. They are operated with 8,500 lbs. per sq. in. working pressure and 2,000 lbs. per sq. in. release pressure. Each shield weighs about 8 tons and cost \$5,000.

Excavation.—The tunnel is through clay which holds a nearly vertical working face and becomes quite hard in places. This clay is excavated principally by means of draw knives of the form illustrated by the sketches in Fig. 11 and the photographic view, Fig. 12. The knives are operated like a draw shave for working wood. When the clay is soft, two men operate the knife, one grasping each handle, but, when the clay is hard, a third man is employed, who also takes hold and bears down. A strip of clay nearly 5 ft. long is shaved off with each stroke of the knife and is passed to a

third man, who rolls it up and casts it over his shoulder to the muckers behind.

The draw knives, made by the contractor's blacksmith, are of $7/32 \times 1\frac{1}{2}$ -in. spring steel self-annealed in air. Two forms of knife are used, one for soft and one for hard clay; the difference in form is in the angle which the cutting edge makes with the handle, this angle being 45° for soft clay and 20° for hard clay. The blades wear down to a width of about $\frac{1}{4}$ -in. and then break at the center. Other details and dimensions are given by the sketches, Fig. 11.

Work is carried on continuously in 8-hr. shifts, the usual arrangement being to operate three shifts of miners in one drift and

Fig. 9.—Tunnel Shield.

two shifts of miners and one shift of masons in the other drift, the masons' shift working the two drifts alternately. Each shift of miners is made up as follows:

	Per shift.	Per 24 hrs.
1 foreman, at \$5	\$ 5.00	\$ 15.00
14 miners, at \$3.75	52.50	157.50
12 muckers, at \$3.25	39.00	117.00
2 valvemen, at \$3.50	7.00	21.00
4 timbermen, at \$3.50	14.00	42.00
3 switchmen, at \$2	6.00	18.00
3 drivers, at \$2.25	6.75	20.25
Totals	\$128.25	\$384.75

This crew is divided between the two drifts and has averaged

7 lin. ft. of excavation per shift in each drift, or 14 ft. per shift in both drifts. The bore being 20 ft. in diameter, there are 11.63 cu. yds. of excavation per lineal foot of tunnel. Therefore, $14 \times 11.63 = 163$ cu. yds. of material are taken out every 8 hours at a labor cost for mining, mucking, timbering and haulage in tunnel of \$128.25, or 79 cts. per cu. yd.

Timbering.—The timbering consists of a solid lining 8 ins. thick composed of rings of 4-ft. segments laid close. This timbering is placed by the mining gangs inside the tail of the shield, and as fast as the shield advances. The segments are prepared in the contractor's sawmill by a separate gang working one 8-hr. shift per day. Since about 495 ft. B. M. of lumber is required for timbering each lineal foot of tunnel, the millwork is an important detail.

The timber used for the lining is rough hemlock, costing \$18 per M. ft. B. M. It is delivered to the work in 6 x 8-in. pieces about 12 ft. long and is then sawed into segments 4 ft. long, 6 ins. wide and 8 ins. deep; each segment has its ends cut to true radial planes and its back to a true circular arc. The machines for this work are installed in a building at the contractor's plant, and consist of

Fig. 10.—Cutting Edge of Shield.

a circular saw, a band saw, a band saw sharpener and minor tools. The circular saw is fitted with a table which swings with just the proper angle with respect to the saw to give the ends of the segments the correct bevel. The band saw cuts the back of the segment to the true circular arc and is fitted with a table which swings on the proper curve to effect this. In operation the 6 x 8-in. pieces are brought to the rear of the building and slid endwise through a window directly onto the table of the cutting-off saw.

The sawyer first takes off a crop end to get the proper bevel; he then turns the stick half-way over, shoves it along the table until the end comes against the stop and cuts it off. The stick is then turned again, pushed ahead against the stop and cut off. These operations are repeated for the third segment. As the segments are sawed off they are piled up by the side of the band saw. The band sawyer takes the pieces one at a time, adjusts them on the swinging table and cuts their backs to the desired arc, and they are ready to go to the work. Each sawyer has one helper, and there are two other laborers to bring the sticks to the mill

and pass them to the cutting-off saw. The sawmill force works one 8-hr. shift per day, and is organized as follows:

	Per shift.
1 fireman, at \$5.....	\$ 5.00
1 engineer, at \$5.....	5.00
2 sawyers, at \$3.50.....	7.00
4 laborers, at \$3.00	12.00
Total	\$29.00

This sawmill gang turns out all the segments necessary to keep the work going in both drifts. The average advance of each drift is 21 ft. per day, and there being 495 ft. B. M. of timber per lineal foot of lining, this gang turns out $495 \times 42 = 20,790$ ft. B. M. of finished segments at a labor cost for sawing of \$29, or about \$1.40 per thousand feet.

Lining.—The 16-in. brick lining inside the timbering is placed

Fig. 11.—Draw Knife.

by a separate mason gang. It amounts to 3.42 cu. yds. of brickwork per lineal foot. The mason gang is organized as follows:

	Per shift.
7 masons, at \$9.....	\$ 63.00
17 helpers, at \$2.75.....	46.75
10 laborers, at \$2.50.....	25.00
2 drivers, at \$2.25.....	4.50
Total	\$139.25

The mason gang lays 20 lin. ft. or 68.4 cu. yds. of lining per shift at a cost for labor and haulage in tunnel of \$2.04 per cu. yd., or \$6.96 per lineal foot.

Haulage.—The muck is hauled from the working faces to the shaft in tunnel and from the shaft top to the spoil bank on surface in cars drawn by mules. The same cars are taken back loaded with brick, lining segments or other materials, so that they run loaded both ways. In the tunnel the hauling is done by the mining and the mason gangs, but a separate lift gang handles the cars on the elevator, and another gang hauls them from the shaft top

to the spoil bank. This spoil bank is located about a hundred yards from the shaft top, since the clay is being saved for sale, it being of a kind particularly suited for certain burnt clay products.

The lift gang works three 8-hr. shifts per day, and is organized as follows:

	Per shift.	Per 24 hrs.
2 cagemen, at \$3.....	\$ 6.00	\$18.00
4 laborers, at \$2.50.....	10.00	30.00
Total	\$16.00	\$48.00

The dump gang works three 8-hr. shift and is organized as follows:

	Per shift.	Per 24 hrs.
1 hoisting engineer, at \$5.....	\$ 5.00	\$ 15.00
1 fireman, at \$4.....	4.00	12.00
16 laborers, at \$2.75.....	44.00	132.00
2 drivers, at \$2.25.....	4.50	13.50
Totals	\$57.50	\$172.50

From these figures we can make an approximation of the cost of hoisting and dumping. Considering the cost of hoisting first, it is

Fig. 12.—Draw Knife.

to be noted that this is divided between the work of hoisting the muck and of lowering the brick, timber and mortar materials. We will, therefore, estimate the total cost of hoisting per day, and prorate this sum between the two. Assuming that one-half the fireman's wages and one-fourth the coal consumption are chargeable to hoisting, we have the following figures:

	Per day.
2 cagemen, at \$3 per shift.....	\$18.00
4 laborers, at \$2.50 per shift.....	30.00
1 hoisting engineer, at \$5 per shift.....	15.00
1/2 fireman, at \$3.50 per shift.....	5.25
5 tons coal, at \$3 per ton.....	15.00
Total	\$83.25

Taking the quantities given elsewhere in the article we can

figure the weight of muck hoisted and the weight of materials lowered per lineal foot of tunnel as follows:

11.63 cu. yds. muck, at 3,000 lbs. per cu. yd...17.45 tons

As 42 lin. ft. of tunnel are excavated each 24 hours, the weight of muck hoisted during that time is 733 tons. Turning now to the materials lowered, we have:

	Tons.
0.91 cu. yds. sand, at 2,700 lbs. per cu. yd.....	1.23
41.2 cu. ft. timber, at 85 lbs. per cu. ft.....	0.72
1,650 bricks, at $4\frac{1}{2}$ lbs. per brick.....	3.71

Total weight of materials.....5.66

This total multiplied by 42 ft. gives 238 tons of materials lowered every 24 hours. The total tonnage of material handled is, therefore, 971 tons at a cost of 8.57 cts. per ton, of which about one-third, or 2.8 cts., are chargeable to lowering materials and two-thirds, or 5.68 cts., are chargeable to hoisting muck. The total yardage of muck hoisted every 24 hours is $11.63 \times 42 = 489$ cu. yds. The estimated cost of operating the hoist for 24 hours being \$83.25, we have $(\$83.25 \div 489) \times \frac{2}{3} = 11\frac{1}{2}$ cts. per cu. yd. as the cost on the above assumptions of hoisting the muck.

The cost of dumping per 24 hours as given above is \$172.50, and a part of this is chargeable to loading materials and hauling them to the shaft head. It is probably fair to assume that at least two-thirds of the total cost is chargeable to hauling and dumping muck. As 489 cu. yds. of muck are hauled and dumped each 24 hours, we have $(\$172.50 \div 489) \times \frac{2}{3} = 23.4$ cts. as the cost per cu. yd. on the above assumptions.

Plant.—The contractor's plant is housed in wooden buildings grouped around the head of the shaft and comprises the following machinery: Power plant: two 100 h.p. boilers, one dynamo and dynamo engine, 20 h.p.; one lift; one emery wheel; one 100 h.p. air compressor; one positive blower and 10 h.p. blower engine; two 50 h.p. hydraulic pressure pumps, and one 40 h.p. cage hoisting engine. Sawmill: one 80 h.p. boiler, one 50 h.p. engine, and the saws, etc., previously itemized. On the dump: one 15 h.p. hoisting engine boiler. The estimated first cost of this plant is \$30,000. About 20 tons of coal per day (24 hrs.) at a cost of \$3 per ton are required to operate it. The plant gang works three 8-hour shifts and each shift is made up of:

	Per shift.	Per 24 hrs.
1 hydraulic pump engineer, at \$5..	5.00	\$ 15.00
1 hoisting engineer, at \$5.....	5.00	15.00
1 fireman, at \$3.50.....	3.50	10.50
1 machinist, at \$4.....	4.00	12.00
1 machinist's helper, at \$2.75...	2.75	8.25
1 electrician, at \$4.....	4.00	12.00
1 blacksmith, at \$4.....	4.00	12.00
1 blacksmith's helper, at \$2.50...	2.50	7.50
1 carpenter, at \$5.....	5.00	15.00
1 trackman, at \$3.50.....	3.50	10.50
1 barnman, at \$3.50.....	3.50	10.50
2 laborers, at \$2.50.....	5.00	15.00
Totals	\$47.75	\$143.25

Office Force.—The office force consists of seven men and its work is divided into two 12-hour shifts. It is made up of:

	Per month.
1 general manager, at \$400.....	\$133.00
2 superintendents, at \$150.....	300.00
2 timekeepers, at \$75.....	150.00
1 receiving clerk, at \$75.....	75.00
1 bookkeeper, at \$75.....	75.00
Total	\$733.00

The general manager has charge of several jobs and about one-third of his time is chargeable to the work being described. Dividing the total wages by 30, we get \$24.33 as the labor cost of the office force per day.

Summary of Costs.—The daily cost of labor, summarized from the above figures, is as follows:

Office force	\$ 24.33
Dump gang	172.50
Lift gang	48.00
Mason gang	139.25
Sawmill gang	29.00
Drift gang	384.75
Plant gang	143.25
Lock tender	9.00
Total	\$950.08

The cost of lumber as given above is \$18 per M ft. B. M., and the cost of coal is \$3 per ton. Estimating the cost of brick at \$9 per thousand, of cement at \$1.50 per barrel and sand at \$1 per cu. yd., we get the following as the cost per lineal foot of the conduit exclusive of interest and depreciation on plant:

	Per lin. ft.
495 ft. B. M. of timber, at \$18.....	\$ 8.91
0.48 ton coal, at \$3.....	1.44
1,650 bricks, at \$9 per M.....	14.85
3.38 barrels cement, at \$1.50.....	5.07
0.91 cu. yd. sand, at \$1.....	0.91
Labor, \$950.08 per day.....	22.63
Total	\$53.80

This does not include the cost of sinking the shaft, nor does it include plant interest, depreciation and repairs.

Cost of a 13½-ft. Sewer Tunnel at Cleveland, Using a Hydraulic Shield.*—The method of building large sewers by tunnelling is becoming increasingly popular, not only because it is usually cheaper than open cut work in soft ground, but because there is no obstruction of streets and no settlement of buildings adjacent to the sewer. Unfortunately, however, the use of a hydraulic shield is little understood by most contractors, and less is known about the actual cost of such work. We believe the following data are the first itemized costs of shield work that have appeared in the technical press; and, while a few of the items are probably not absolutely correct, the data are reliable in the main, and serve to give

**Engineering-Contracting*, July 25, 1906.

a very close estimate of the cost of similar work. Before giving the figures of cost, a word as to the conditions:

Most of the main intercepting sewer of Cleveland, Ohio, was built in open cut, the top width of trench being 20 ft. and the depth averaging 40 ft. Two sets of Wakefield sheet piling were required, the upper set being 28 ft. long. The sheet piling was well driven, but in passing certain brick buildings, enough quicksand leaked under the sheeting to cause a settlement of the buildings, and resulting cracking of the walls. The trench was through dry sand, wet sand, quicksand, and clay and sand mixed. As a result of the damage to one building it was decided to build the remainder of the sewer by the tunnel method. The contract price for the 18½-ft. sewer in open cut (40 ft. deep) had been \$71 per lin. ft. The contractor agreed reluctantly to undertake the building of the sewer by the tunnel method for \$60 per lin. ft., and, as we shall see, made a good profit at this price. The tunnel work proceeded day and night at a rate of 150 ft. a month, as compared with 125 ft. per month when the open cut method was used. One advantage of the tunnel work is that it can be carried on continuously, day and night, and there is no interruption on account of bad weather. Moreover, it requires fewer laborers than the open cut method, under the conditions above stated.

The secret of the modern success in driving tunnels through quicksand and other soft materials lies in the use of the hydraulic shield. A shield is a section of steel tube, open at both ends. The forward end is provided with cutting edges, and, in very soft materials, it is provided with trap doors through which the material is excavated. The shield is shoved forward about 3 ft. at a time, by means of hydraulic jacks; and the tunnel lining is built up inside the rear part of the shield, ready for the next shove. In this particular case a brick lining was used, and the hydraulic jacks bore against blocks of wood laid on this lining when shoving the shield ahead. Where the ground is so porous that the water flows in faster than it can be pumped out, the tunnel is kept full of compressed air. The pressure of the air depends entirely upon the pressure of the outside water at the face of the shield. In this particular work an air pressure of 5 lbs. per sq. in. was ordinarily sufficient, although in a few soft spots a pressure of 9 lbs. was used. With such low pressures as these there is no danger that the men will get the "bends." And there is no danger of "blowouts" at the face of the shield where the air pressure is light, and the covering of earth over the shield has a fair thickness. In a word, this sort of sewer tunneling by the shield method is not at all hazardous; and, it is surprising, indeed, to note how few contractors have had the courage to try it. Perhaps the stories of the difficulties encountered in driving tunnels under rivers (which is a wholly different matter) have served to frighten contractors and engineers generally.

Regarding keeping the shield to line and grade, no difficulty need be experienced in sewer work of this character. By making a

mark in the earth at the face of the shield, it is easy to see whether the shield is moving in a straight line or not. If the shield is moving off to one side, simply relax the pressure on the hydraulic jacks of the opposite side, and the shield is easily brought to line. In similar manner it is kept to grade. The jacks are so connected by piping that any one of them can be cut out. All that is needed is careful watching, and the shield can be easily kept to line. A cut showing the general dimensions of the shield is given herewith (Fig. 13).

We now come to the details of the work.

The sewer is $13\frac{1}{2}$ ft. in diameter and was built of four rings

Fig. 13.—Tunnel Shield.

of No. 1 shale brick laid in Portland cement mortar. The masonry, from a point 2 ft. below the spring line to a point 4 ft. from the crown of arch, was laid in Flemish bond, keyed in with row-lock masonry.

The air lock consisted of a section of the sewer included between two brick bulkheads, 2 ft. thick and 24 ft. apart. A wooden door made of 4-in. tongued and grooved timber was placed in each bulkhead. When closed the doors press against rubber gaskets to prevent leakage. The lock was supplied with large valves so that it could be filled or emptied in about one minute. The ordinary air pressure was about 5 lbs., and it was found that this was sufficient

to keep the tunnel dry and to give a good supply of fresh air to the workmen. When soft spots occurred in the excavation the pressure was run up to about 9 lbs. A higher pressure than this might have caused a "blowout" as the hard material in the roof of the tunnel was not particularly thick.

The shield, a section through the center of which is shown in Fig. 13, was constructed of $\frac{3}{4}$ -in. steel, and had a total weight of about 16 tons. The shield was 4 ft. long and $16\frac{1}{2}$ ft. in diameter. The upper half was provided with a follower, 7 ft. long, made of $\frac{3}{4}$ -in. steel, bolted to the shield. When the roof was of hard material the "follower" was pulled off the brickwork about $2\frac{1}{2}$ ft. The shield was pushed forward by 12 hydraulic jacks, 5 ins. in diameter and $26\frac{1}{2}$ ins. long. The water is conveyed to the jacks by a pipe line containing a swinging joint in the shape of an inverted "V" with the joint at the apex, which allowed the shield to be shoved ahead and pulled the pipe with it. The average pressure used in shoving the shield was about 700 lbs. per sq. in., but the pump could develop a pressure of 6,000 lbs.

The material excavated was principally a hard, dry quicksand, at times mixed with clay. All material was handled in cars of a 1 cu. yd. capacity, the cars being pushed in and out by the laborers.

The method of excavation was as follows: The miners excavated about 3 ft. in advance of the shield, the pressure was then applied and the shield shoved ahead into the part just excavated. At the beginning of each day's work the heads of the jacks stood about 1 ft. from the brickwork. Large wooden blocks were then placed against the two outer rings of the brickwork and other blocks were placed between these and the heads of the jacks. The pressure transmitted to the brickwork did not damage it. After the first shove of 2 ft., the jacks were forced back and more blocking placed between them and the other blocks.

The sewer for part of the time, at least, was constructed at the rate of 9 ft. a day or about 250 ft. a month. An additional foot a day could easily have been made but the contractor did not care to take too great chances by pulling the shield follower off the brickwork any further.

Two brick layers laid up the 9 ft. of sewer in about 8 hours, each man laying about 5,000 bricks. The mortar was mixed in the tunnel at the face of the work. In each lineal foot of sewer there were 8 cu. yds. of excavation and 2.62 cu. yds. of masonry, or about 1,100 bricks per lineal foot.

The work was divided into four shifts, the wages and number of the men in each shift being as follows: the superintendent's were the contractor's sons, their wages being estimated at \$5 per day:

1 Head Miner at \$4.00.....	\$ 4.00
3 Miners at \$3.50.....	10.50
2 Muckers at \$2.50.....	5.00
1 Double Team at \$5.00.....	5.00
Total	\$ 24.50

Second Tunnel Gang, 7 A. M. to 3 P. M.:

Same number as first gang.....\$ 24.50

Total for tunnel gangs.....\$ 49.00

Brick Shift, 3 P. M. to 10 P. M.:

2 Bricklayers at \$8.00.....\$ 16.00

4 Tenders at \$1.75.....7.00

2 Car Pushers at \$1.75.....3.50

Total\$ 26.50

Top Gang, 7 A. M. to 5:30 P. M.:

4 Laborers at \$1.50.....\$ 6.00

Day Shift, 7 A. M. to 7 P. M.:

1 Superintendent at \$5.00.....\$ 5.00

1 Engineer at \$3.25.....3.25

1 Fireman at \$1.75.....1.75

1 Carpenter at \$2.00.....2.00

4 Car Pushers at \$1.75.....7.00

Total labor for 24 hours.....\$121.00

The two tunnel gangs worked 8 hours each, and the total wages paid them were \$49 for 16 hours, during which time they excavated 9 lin. ft., or 72 cu. yds. Hence their labor cost \$5.44 per lin. ft., or 68 cts. per cu. yd.

The two top gangs worked 12 hours each, and their total wages were \$39.50. In addition to this there was the fuel for a 60-hp. boiler, which could not have exceeded 4 tons in 24 hours, and, doubtless, was much less. Assuming 4 tons at \$3, we have \$12 to be added to the \$39.50, making \$51.50, or \$2.15 per hour. In the 16 hours of excavating work, the cost of the top labor and fuel would be $16 \times \$2.15 = \34.40 , which is equivalent to \$3.82 per lin. ft. of tunnel, or 48 cts. per cu. yd. The total cost of excavation was, therefore, \$0.63 plus \$0.48, or \$1.16 per cu. yd., exclusive of interest and depreciation of plant.

The brick mason gang worked 7 hours, and the total wages were \$26.50. Since 2.62 cu. yds. of brick masonry were laid per lin. ft., there were 23.6 cu. yds. laid each shift, the advance being 9 lin. ft. Hence the cost of labor was \$1.12 per cu. yd., of \$3 per M, or \$2.95 per lin. ft. But this does not include the wages and fuel charged to the surface gang, which is \$2.15 per hour, or \$17.20 for 8 hours. Distributing this \$17.20 over the 23.6 cu. yds. of brick masonry we have 73 cts. per cu. yd. of masonry, or \$1.91 per lin. ft. of tunnel. The total labor cost

of brick masonry is, therefore, \$1.12 plus 0.72, or \$1.85 per cu. yd. We are now able to approximate the cost of the tunnel per lineal foot.

	Per lin. ft.
8 cu. yds. excav., underground labor, at \$0.68.....	\$ 5.44
8 cu. yds. excav., surface labor, at \$0.48.....	2.82
2.62 cu. yds. brickwork, underground labor, at \$1.12.....	2.95
2.62 cu. yds. brickwork, surface labor, at \$0.72.....	1.91
1,100 bricks at \$9 per M.....	9.90
2.1 bbls. cement (1:3 mortar) at \$1.70.....	3.57
1 cu. yd. sand at \$1.00.....	1.00
Plant, 50 per cent of first cost, distributed over 1,625 lin. ft..	5.00
35 ft. B. M. floor of tunnel at 3 cts.....	1.05
Shafts or manholes.....	1.00
Total	\$35.64

The plant is estimated to have cost about \$16,000, including \$3,000 for track rails, pipe, wire and lamps; and we have assumed that half of this \$16,000, or \$8,000 should be charged to the 1,600 lin. ft. of tunnel, which is \$5 per lin. ft.

The tunnel was temporarily floored with plank, and upon this the tracks were laid. We have estimated that this flooring need not have exceeded 35 ft. B. M. per lin. ft. of tunnel.

No data are available for accurately estimating the cost of shafts, but it is safe to assume \$1,600 for the 1,600 ft. of tunnel as the cost of shafts.

It will be remembered that the above costs are based upon a progress of 9 lin. ft. per 24-hour day. Very bad material might reduce progress to 6 ft. per day, correspondingly increasing the cost of labor.

The contractor's plant on this tunnel work was as follows:

3 boilers, 60 hp., return flue, only one in use at a time.

1 Duplex feed pump, 4-in. steam cylinder, 3-in. water cylinder, 5-in. stroke, made by Laidlaw & Dunn, Cincinnati, O.

1 straight line air compressor, class "A," 16-in. steam cylinder, 16½-in. air cylinder, 18-in. stroke, made by Ingersoll-Rand Co., New York City.

1 vertical high speed engine (20 hp.) for dynamo, cyl. 8 x 10 ins.

1 dynamo with rheostat, capacity 250 incandescent lights, 110 volts, 55 amperes.

1 Norton voltmeter and switches.

1 high pressure hydraulic pump, 16-in. steam cylinder, 1-in. water cylinder, 12-in. stroke, made by the National Pump Co., Chicago.

1 hoisting engine, double cylinder, 8 x 10 ins., with one drum (22 x 22 ins.), sink motion reverse, made by J. S. Mundy, Newark, N. J.

1 pump shaft, steam cyl., 5¼ x 4 ins., made by Knowles Steam Pump Co., 114 Liberty St., New York.

1 elevator cage and guides.

12 hydraulic jacks (5 x 26 ins.), with valves, for shield.

1 shield, weight 22,000 lbs.

In conclusion it should be said that this work was done without the slightest settlement of adjacent buildings, although a 3-story brick building was with a few feet of the line of the sewer.

The contractor was Mr. John Wagner, of Cleveland, O. Mr. J. M. Estep was Assistant Engineer Intercepting Sewers, and to him we are indebted for the data upon which the above given costs are based.

Cost of Sewer in Tunnel, Cleveland, O.*—The tunnel construction is a portion of the contract for the Lakeside Ave. intercepting sewer, between E. 40th and Marquette streets in Cleveland, Ohio, Mr. Thomas W. Nicholson, contractor. For some of the intercepting sewer, brick, with internal diameter of 12 ft. 6 ins., approximate depth to bottom of sewer 40 ft., the price per lineal foot in open cut was \$32. In spite of all the care taken by the contractors to brace the trench it broke away from them in places until at some spots the sinking of the street extended to the curb line. Much trouble was experienced with settlement of buildings with the drawbacks incidental to such happenings. The contractors were in so much trouble that they were permitted to tunnel and no more trouble was experienced with buildings settling and there was an immediate reduction in the cost of the work.

The sewer now being put in by Mr. Nicholson was let to him for \$22 per lineal foot when using three rings of brick with wood backing, his price for four rings of brick without the wood backing being \$26. There were a number of other bidders who all bid higher for the wood backing form of construction, than for the four rings of brick, internal diameter of the sewer 12 ft. The work is now in progress. It may be interesting to note that on Aug. 4, 1902, a contract was let for another section 3,430 ft. long, to John Wagner, the internal diameter being 12 ft. 3 ins. at a price of \$22.72 with wood backing and \$22.72 for all brick. The cost to the city is thus less than half by tunnelling compared with the open cut work and the dangers supposed to be guarded against by open cut work are really less with the tunnel. On his present contract for the 12-ft. sewer Mr. Nicholson is said to be meeting with no trouble by reason of settlement of buildings.

To get rid of water and prevent settlement by a too rapid unwatering of the ground, the tunnel is constructed under air pressure of about 7 lbs. to the sq. in. Men work in this pressure for a whole shift, the work being continuous in 8-hour shifts. A shield is used and an attempt is made to complete a 12-ft. length in each shift. The table given shows the progress made during August and September, up to the time the tunnel was visited.

**Engineering-Contracting*, Oct. 5, 1902.

The material being a fine joint clay is shaved by knives. These knives are made like a carpenter's draw knife, or shave knife, with the blade bent to a half circle. Small ones can be used by one man but in this tunnel the air makes the clay dense and several men pull on the knives, thus being enabled to take off long slices. When 2 ft. of excavation are gained the shield is driven ahead, and the wood lining put in. This wood lining consists of blocks of wood about 2 ft. long, 8 ins. wide and 6 ins. thick. On one side a curved piece is cut so the face of the block is cut to a radius of 7 ft. 1 in. The piece removed is nailed on the back and thus the block is 8 ins. wide and 6 ins. thick but front and back both curved to a radius. The excavation is 38 ins. larger than the interior diameter of the sewer and the wooden blocks are used to line the entire excavation, making a wooden ring with the inside face 18 ins. larger than the sewer. The jacks of the shield press against this wood lining and the pieces being cut to fit, any pressure exerted on the side of the excavation will simply force the ends of the blocks together and no other bracing is required. This leaves the space clear for the brick masons.

The masons lay three rings of brick on the wooden ring for one-half the height. Great care is taken to insure grade and as the excavation, if anything, is usually slightly in excess, the extra space is filled with cement mortar. The inside diameter of the sewer is therefore true. When the sewer is completed on either side to the middle, braces are spiked to the ends of the ties of the material track and leaning against the sides of the sewer. Upon the upper ends of these braces are placed heavy timbers carefully leveled and resting upon these timbers are placed semi-circular steel centers made from 4 in. channels, with feet riveted to them to enable them to be maintained in a vertical position. These centers are placed 4 ft. apart and the total length of brickwork put in on a shift is generally 12 ft., requiring three centers. The space between the brickwork and the centers is sufficient to permit the placing of 3 in. lagging on the centers.

Against the lagging the masons lay the brick horizontally on the sides, presenting the narrow edge to the inside of the sewer. The three rings are thus laid and if any spaces exist between the brick and the wooden lining it is easy to slush them in. At the top, arrangements are made to place lagging for 3 ft. across, instead of lengthwise, and thus 1 ft. at a time can be built and cavities taken care of. Brick and mortar are carried in by cars drawn by a mule on ordinary industrial track. Double lines of track are laid with frequent switches and cross overs. All the excavated material is taken out on these tracks and the brick and other materials brought in. There is one shaft from which work is carried in two headings but only one heading was being worked at the time of the visit. The equipment at the shaft head consists of a hoisting engine and air compressor and in the tunnel is a pump to force out the water when it becomes troublesome. The air lock is at the foot of the shaft and about 25 ft. long. The

SEWERS, CONDUITS AND DRAINS.

895

tunnel was in about 2,000 ft. when visited and under air the whole length.

A usual working force consists of 11 men, according to the city sewer inspector, divided about as follows:

Miners	8
Men placing blocks.....	2
Muckers	2
Mule driver.....	1
Total	11

This exact division is not adhered to as all the men help the miners except when blocks are to be placed, when some of the laborers are detailed for that work. There are generally two masons with four or more helpers.

The men are paid by the shift and the inspector did not know what they were paid but from conversation with the men he gathered that the rates of pay are about as follows:

	Per hour.
Masons	\$1.00
Helpers	0.25
Miners	0.30
Laborers	0.25

The following table is copied from the inspectors daily reports and collected for each week from tables prepared in the office of the city engineer. It will be noted that the laborers' hours are lumped, regardless of the work performed, no distinction being made between miners, muckers and helpers.

Engineers from the sewer department go into the sewer daily to keep up the line and grade points. For grade, nails are driven in each side at a definite height at intervals, and strings are stretched from nail to nail across the sewer when the men want to check their grade at any time. Upon the strings pieces of paper are hung and sights are taken across two or more strings. In this way it is easy to keep it almost exactly on the grade with the work. Owing to soft places encountered from time to time in the material, it is more difficult seemingly to preserve the line than the grade. The alignment, however, seemed excellent and the work was creditable to the contractor and the men in charge for the city.

Week ending.	Foreman.	Engineer.	Hours Masons.	Helpers.	Laborers.	Feet of sewer completed.

The cost was as given in Table XI.

TABLE XI.—LABOR COSTS PER FOOT OF SEWER.

Week ending.	Foreman.	Engineer.	Mason.	Helper.	Laborer.	Total labor cost per foot.
Sept. 18....	\$0.68	\$0.56	\$1.62	\$2.02	\$6.56	\$11.45
Sept. 11....	0.82	0.66	1.57	1.96	6.52	11.53
Sept. 4....	2.33	1.87	1.33	1.11	6.20	12.84
Aug. 28....	0.87	0.69	1.59	2.04	7.00	12.21
Aug. 21....	0.76	0.61	1.44	1.80	6.59	11.20
Aug. 14....	0.83	0.67	1.58	1.98	7.92	12.98
Aug. 7....	0.68	0.54	1.55	1.83	5.71	10.41

The wages are assumed to be correct as given by the inspector. The wages for laborers are assumed at an average of 27½ cts. per hour; foreman assumed 50 cts. per hour; engineer assumed at 40 cts. per hour. This analysis is made upon the foregoing data solely and has not been checked with information from the contractor.

The foregoing labor cost takes the wood, brick, mortar, etc., down into the tunnel; puts them in place and the excavated material is brought to the surface to be hauled away. This hauling must add \$2 per foot to the cost unless some arrangements are made to dispose of the material at a profit.

Each foot of excavation contains 6.7 cu. yds. In each foot there are 800 brick and 276 ft. B. M. of lining blocks. The mechanical equipment consists of a shield, a hoisting engine, air compressor and two pumps; one in each heading and of tracks for cars, cars, mules, piping, etc., and locks. For this equipment and operation a charge of \$1.25 per foot should be reasonable as it will not be worn out on this one job.

The following estimate should be about right for similar work:

Plant, fuel, etc.....	\$ 1.25
800 brick at \$15 per M.....	12.00
Mortar	1.22
Wood lining, 276 ft. B. M. at \$35.....	9.63
Hauling away material.....	2.00

Cost per foot exclusive of labor.....\$26.16

The labor costs vary as shown from \$10.41 to \$12.98 per foot, which brings the cost per foot from \$36.57 to \$39.14, the contract price being \$32.

When both headings are going the cost for foreman and engineer will of course be divided but this will cut off less than \$1 per foot. If the excavated material is sold the price cannot more than pay the cost of hauling. Assuming everything favorable that can be assumed, it looks as if the contract is not going to be very remunerative.

The men lumped together as laborers handle all the material into and out of the tunnel, do the mining, cleaning up, assisting brick masons, helpers, etc., so the actual excavation cost is less than \$1 per cu. yd. The cost of masons and helpers is about \$2.80 per 1,000 brick. No fault can be found with these items.

Labor Cost of a Large Brick Sewer in Chicago.*—In 1901 the

*Engineering-Contracting, May 30, 1906.

City of Chicago began the construction of the south arm of its intercepting sewer system, comprising Section G, which extended from 39th street to 51st street, and Sections G 3 and H, which extended from 51st street to 73d street. The work was done by day labor under the supervision of the city's engineers. Descriptions of the methods and cost of driving sheet piling and of the excavation for these sewers were given in the March and April issues of this magazine.

The specifications for the brickwork on Section G called for five rings of hard burned sewer brick, laid in natural cement mortar, composed of one part cement and one part sand. From 39th street to 44th place, the sewer was 16 ft. in internal diameter, and from 44th place to 51st street, it had an internal diameter of 15½ ft. Bricklaying on Section G was commenced in the early part of June, 1901, and was completed about March 1, 1903, no work being done during the winter of 1901-2. On account of the necessity of getting through the freight yards of the Illinois Central Ry. at 51st street, bricklaying was carried on during the winter of 1902-3 when the weather would permit. At no time was brick laid when the temperature was lower than 15 degrees above zero. The best quality of torpedo sand, thoroughly heated was used in the mortar. This section of the conduit was about 300 ft. long.

The brick were unloaded from the cars and placed in piles about 16 ft. from the side of the trench. From these piles the bricks were loaded and wheeled to the side of the trench, and were then delivered to the bricklayers by means of tossers working on the bank and on scaffolds on the braces. All cement mortar was mixed by hand and lowered in galvanized iron pails by means of ropes, from scaffolds on the top set of braces.

During the season of 1901, eight bricklayers were employed, and an average of about 22 ft. of conduit was built per day. This was equivalent to about 40.5 cu. yds. of brickwork per day, or 5 cu. yds. per mason. The second year, 13 bricklayers were used, and they averaged about 35 ft. of conduit per day. It should be remarked that while 13 bricklayers were carried on the roll at this time, the gang usually consisted of 12 men. The gang for handling brick, mixing cement, etc., consisted of from 70 to 75 men for 12 bricklayers.

On the construction of that portion of the intercepting sewer lying between 51st street and 73d street, the first brick was laid Dec. 8, 1901. But 144 ft. were finished that year owing to the cold weather. Construction was resumed about March 15, 1902, and continued until Jan. 2, 1903, when it was stopped for the winter. The work was resumed April 10, 1903, and was completed July 10. The masonry consisted of five concentric rings of brick laid in natural cement mortar, composed of one part cement and one part sand. From 51st street to 56th street the sewer was to have an internal diameter of 14½ ft.; from 56th street to 63d street the diameter was 13½ ft.; from 63d street to 70th street,

12½ ft., and from 70th street to 73d street, 12½ ft. The excavated sections were 48 ft. long, and consequently 12 bricklayers were employed most of the time. The work was so arranged that as soon as the invert was finished, work was begun on the arch. The arch work was usually kept at least one day behind the invert in order to give plenty of room for setting up centers, removal of timbers, and at the same time keep the mason gang busy, if there should be any delay in excavating the bottom or from other causes.

Brick were delivered in cars on the street by the Municipal narrow gage railway, no hand wheeling being necessary. When dumping space was available, sufficient brick for half the invert were usually on the bank before the masons began to work. The brick were passed from hand to hand to the masons.

As in the construction of Section G, the cement was mixed by hand, the mixing being done as close to the workers as possible, but on the opposite side of the trench from the brick pile. The mortar was lowered by hand, one man supplying three masons, that number being allotted to each 12-ft. section. The division was made on account of the Potter trench machine bents, which were so low that a man could not pass under them while on the cement platform. The cement platform was laid on the cross timbers which supported the trench machine. The platform was about 1 ft. above the street surface, thus making a lowering distance of from 22 ft. to 28 ft. when mortar was delivered for the invert. A departure was made from the usual custom of having the mason tender dump the mortar, in that one man in the bottom was assigned to do this work. This proved a decided advantage as the mortar boxes were always kept filled. It might be well to note here that while a mason tender could have handled the mortar for a part of the time, yet even a delay of a few minutes for one mason at frequent intervals, amounts to considerable at the end of the day. Every contractor knows that a slight excuse for slow work will make a considerable difference in the amount of finished product.

When 12 masons were working the mason gang consisted of from 58 to 65 men. The gang included masons, tenders, brick tossers and cement handlers. With this force, from 38 to 44 ft. of completed sewer were built daily.

The mason gang was as follows:

	Rate.	Per Day.
1 Foreman	\$10.00	\$ 10.00
12 Masons	9 00	108.00
11 Bottom tenders.....	3.25	35.75
7 Bank men.....	3.50	24.50
7 First scaffold men.....	2.50	17.50
7 Second scaffold men.....	2.50	17.50
7 Third scaffold men.....	2.75	19.25
6 Cement mixers.....	2.75	16.50
5 Cement carriers.....	2.75	13.75
5 Cement lowerers.....	2.75	13.75
3 Wheelers	2.50	7.50
5 Sand men.....	2.50	12.50
3 Laborers	2.50	7.50
Total per day.....		\$291.50

As an average of 38 ft. of sewer was built each day, the labor cost per foot is about \$7.93. Assuming that the inside diameter of the sewer was $13\frac{1}{2}$ (some sections were $14\frac{1}{4}$ ft., $13\frac{1}{4}$ ft. and $12\frac{1}{2}$ ft.) the labor cost for the brick masonry amounted to \$2.48 per cu. yd.

It will be noticed in the above tabulation that the rates of wages in many cases were excessive. All that it is necessary to say in regard to this is that the work was done by the city.

Cost of a Concrete and Brick Sewer.—Mr. William G. Taylor, City Engineer of Medford, Mass., gives the following data of work done in 1902, by day labor, for the city. Figure 14 is a cross-section of the sewer, which has a concrete invert and sides and a brick arch. The concrete was 1:3:6 gravel. The forms for the invert were made collapsible and in 10-ft. lengths. The two halves

*Cement Concrete
sand, & gravel*

Fig. 14.—Concrete and Brick Sewer.

were held together by iron dogs or clamps. The morning following the placing of the concrete the dogs were removed and turnbuckle hooks were put in their places, so that by tightening the turnbuckle the forms were carefully separated from the concrete. The concrete was then allowed to stand 24 hrs., when the arch centers were set in place. These centers were made of $\frac{1}{2} \times 1\frac{1}{2}$ -in. lagging on 2-in. plank ribs 2 ft. apart, and stringers on each side. Wooden wedges on the forward end of each section supported the rear end of the adjoining section. The forward end of each section was supported by a screw jack placed under a rib 2 ft. from the front end. To remove the centers, the rear end of a small truck was pushed under the section about 18 ins.; an adjustable roller was fastened by a thumb screw to the forward rib of the center; the screw jack was lowered allowing the roller to drop on a run board on top of the truck; the truck was then pulled back by a tail rope until

the adjustable roller ran off the end of the truck; whereupon the truck was pulled forward, drawing the center off the supporting wedges of the rear section. In this manner not the least injury was done to the fresh concrete.

Each lineal foot of sewer required $1\frac{1}{4}$ cu. yds. of excavation; 4 cu. ft. of concrete, and 1 cu. ft. of brick arch. The sewer was 1,610 ft. long and was built by day labor, wages being \$2 for 8 hrs. The material excavated was gravel and clay.

Excavation and backfill:

Labor, mason.....	1.343	0.049
Labor, helpers.....	2.091	0.077
Carting	0.680	0.025
Incidentals	0.340	0.012
Total	\$12.070	\$0.442

*The gravel and sand were obtained from the excavation.

†This includes cement used in plastering the arch.

The cost of this 30-in. sewer was, therefore, \$1.44 per lin. ft., exclusive of the excavation which cost 74 cts. per lin. ft. The cost of brickwork in manholes was \$15.34 per cu. yd. It should be noted that wages were high (\$2 per 8 hrs.) and that the work was done by day labor, thus making the cost higher than it would be to a contractor.

Cost of a Concrete Sewer.*—The work consisted of a sewer 1,360 ft. long and 30 ins. inside diameter, with a 4-in. shell, constructed during November and December, 1908, with the thermometer ranging 16 degrees above zero to above freezing point. The necessity of using frost preventives added about $2\frac{1}{2}$ cts. per lin. ft. to the cost of the work. The following is a description of the sewer and its construction. The location of the work was at Fond du Lac, Wis.

About four years ago the city dug an open drain along a highway upon the outskirts of the city for carrying storm water into

**Engineering-Contracting*, Jan. 27, 1909.

De Neveu creek. On account of the ditch washing into the road it was decided to place a pipe in this trench and backfill over it. The contract was awarded to Burett & Dooley for a monolithic concrete sewer.

It contained about $1/9$ cu. yd. of concrete per lineal foot. In addition there were 17 cu. yds. of concrete in the two abutments or portals at the ends of the sewer.

The itemized total cost of the sewer was as follows:

Items.	Total.	Per lin ft. Cts.
Labor	\$636.50	46.73
Tools	24.59	1.81
Sandy gravel	208.40	15.22
Lumber	14.04	1.03
Water	11.85	0.88
Frost preventives	34.38	2.53
Cement	370.19	27.23
Steel forms	204.35	15.02
Engineering	182.00	9.71
Totals	\$1,534.80	\$1.20

In this statement the labor item is for unskilled laborers at \$2 per day, working from 8 to 14 men a day for 29 days and 2 foremen at \$3 each for 31 days. The cost items for tools, lumber and frost preventives are the differences between their purchase prices and what they brought when afterwards sold. The sandy gravel was purchased delivered from three different pits at \$1.50 per load of about 1.75 cu. yds., with some at 10 cts. extra per load; it cost, therefore, about 89 cts. per cu. yd. The gravel was mixed to obtain the greatest density of aggregates, and 5 parts of gravel were mixed with 1 part cement to make the concrete. The cement cost \$1.70 per barrel delivered in sacks, less the rebate on sacks returned. Water cost for hauling only 35 cts. per load. The lumber was used for abutment forms and for establishing grades. The frost preventives consisted of horse stable manure, marsh hay, and a thin layer of flax straw sewed between two sheets of rosin paper and also fuel for heating the concrete materials. The steel forms were rented and the cost includes drayage to and from the job and a small sum for oil to grease them. The charge for engineering covers the entire expense to the city and township for plans, specifications, advertising, inspection of sewer during construction, etc.

Separating the abutments containing 17 cu. yds. of concrete the cost was as follows:

Items.	Total.	Per cu. yd.
Labor	\$25.50	\$ 1.50
Tools	00.59	0.035
Gravel	15.00	0.882
Cement	32.01	1.882
Lumber	40.04	0.237
Water	00.60	0.035
Frost preventives	1.88	0.110
Centers	0.75	0.045
Engineering, etc.....	5.00	0.295
Totals	\$85.37	\$5.021

Some of these items are actual amounts and others are close approximations. The costs for the sewer proper arrived at in the same manner were as follows:

Items—	Total	Per Lin. Ft.	Per Cu. Yd.
Labor or concrete.....	\$253.00	\$0.187	\$1.682
Labor excavation.....	367.00	0.262	2.367
Tools	24.00	0.017	0.152
Gravel	193.40	0.142	1.276
Lumber	10.00	0.007	0.062
Water	10.70	0.008	0.072
Frost preventives.....	21.50	0.024	0.216
Cement	228.12	0.249	2.241
Center molds.....	202.60	0.149	1.341
Engineering	127.00	0.092	0.827
Totals	\$1,549.42	\$1.139	\$10.251

In the above table the amount for the concrete labor includes the labor cost for heating the materials, mixing and depositing the same in position complete, also for the small expense of operating the steel forms. The rest of the labor expense was for excavating the trench an average depth of 3 ft. and for back filling. This was done, as noted previously, in an old ditch, the bottom of which was red clay soil, requiring but a slight expense for trench bracing. No water ran in the trench except on a couple of days it rained when the water ran out soon through the molds into the sewer.

Flax straw, bound in paper, already put up, was tried as a cover to the fresh concrete pipe, to keep frost away while the cement was setting, but the vapor from the concrete softened the paper cover so that it could not be handled and the article had to be discarded. The horse stable bedding of straw proved to be efficient for keeping frost out of the green concrete, it generating a certain amount of heat and allowed the moisture to pass through it from the heated concrete. Due to the chemical changes going on in this cover, too strong an article should not be laid next to fresh concrete, as in some places on the pipe it was observed that the cement did not set well for a depth of 1/16 to 1/8 in. A thin layer of marsh hay was placed between the manure and the concrete on the balance of the work and the condition did not appear again.

In the steel forms lighted oil heaters were placed at short intervals to keep up summer conditions while the cement made its initial set.

The style of the centers used was the full circle form so that the crown and invert of the pipe were built in one operation. The materials were mixed on a flat No. 12 gage steel sheet, size 60 x 156 ins. Concrete was put in the bottom of the trench first, which was dug somewhat rounding, and graded 4 ins. thick. Strips of No. 20 gage sheet steel 12 ins. wide by 8 ft. long, previously rolled to the arc of 36-in. circle, was next laid, one piece lengthwise on this bed, then one 5-ft. section of steel forms was placed upon the strip, or track. The form was expanded to size by turning the hand wheel, the correct diameter being obtained by fitting a wire hoop

gage around the near end of the center and expanding the center against the gage. Another batch of concrete now ready was positioned around the form, an operator at the front end of the form having a steel blade, 5 ins. wide by 10 ins. long, affixed to a long handle, tamped the concrete firmly to place under the two bottom quarters of the form so that the possibility of voids or pockets forming in the bottom of the concrete pipe to be refinished later was eliminated, the concrete being positioned on top of the

Fig. 15.—Centers for Concrete Sewer.

form nearly out to the end. Another form being set, the process described was repeated.

The object of using a light steel track, or slide, under the forms, was so that the molds could be drawn out easily the next morning one at a time, and to prevent scraping out partially set concrete from the bottom of the sewer, the steel track being laid with lapped ends so that the forms could slide over the joints and not disturb the track. The track was, of course, taken each

morning from the sewer after the centers were withdrawn and used repeatedly.

Collapsing of the centers was accomplished by merely giving the hand wheel a few turns to the left, when the mold was pulled out of the sewer with a rope and taken ahead in the trench for re-setting when needed. No bracing of the forms was required to keep them in alignment. The top of the concrete pipe was shaped with a wood hand float, the concrete for this purpose not being made wet enough to make it sloppy.

The adjustable steel centers as used on this job were handled on the desirable unit plan; however, all the forms may be set before placing concrete about them, or in any other way that may appeal to a contractor as most advantageous. Two Y-connections were made to this sewer by placing the small ends of clay pipes against the steel forms as the concrete was being positioned. The next morning when the steel forms had been removed the first connection had some concrete to be broken out of the end and refinished, while the one made later was found perfect. Gas engine oil thinned with kerosene and applied with a brush to the surface of the molds prevented the adhesion of concrete to the forms. The temperature varied during construction when concrete was made from 15° above zero to above the freezing point. The thermometer one morning registered 12° below zero, but by 10 o'clock it showed 15° above when concreting was started. One foreman with a crew of six men often put in 70 ft. of sewer in less than 5 hours' time.

The style of mold used on this job is patented by J. E. Dooley, and is manufactured by the Adjustable Steel Centering Co. of Fond du Lac, Wis. We are indebted to the contractors, Burrett & Dooley, for the information from which this article has been prepared.

Cost of Reinforced Concrete Sewer at Cleveland, O.—Mr. Walter C. Parmley, M. Am. Soc. C. E., gives the following data: There were $2\frac{1}{4}$ miles of reinforced concrete sewer, 18 $\frac{1}{2}$ ft. diameter, of section shown in Fig. 18, and 18 ins. thick at the crown. The contract price was \$62 per lin. ft., including excavation, and the excavation averaged 20 cu. yds. per lin. ft. The bid for a brick sewer was \$76 per lin. ft.

It will be noted that there are two rows of "anchor bars" buried in the side walls. The invert and side walls were first built up as high as the top of the brick lining, then the arch centers were placed, and the steel skeleton was bolted to the anchor bars. The ribs of this steel skeleton were spaced 15 ins. centers, and there were 3 rows of horizontal or longitudinal bars of 1 $\frac{1}{2}$ x $\frac{1}{4}$ -in. steel bolted to the ribs. The metal was all bent to shape in the shop, so that there was no field work except to place and bolt the metal together. There were 33 lbs. of steel per lin. ft. of sewer, of which 55 lbs. made the skeleton in the arch, and 27 lbs. of anchor bars. This design of steel skeleton was patented by Mr. Parmley.

The lagging of the arch centers was covered with building paper water-proofed with paraffine. Then Portland cement mortar 3 to 3 ins. thick was plastered on the paper, so as to form the interior

finish of the arch. Then the concrete for the arch was placed and rammed, being 12 ins. thick at the crown and 16 ins. thick at the spring line. No outside forms were used on the arch. The arch concrete was 1:3:7½. When the paper lining was pulled off a smooth surface was left. The invert concrete was made with natural cement.

Mr. Parmley had an inspector keep a record of progress for several days on the work, when the men did not know they were being

1444

Fig. 16.—Reinforced Concrete Sewer.

timed. He informs me that an 8-hour shift was worked. The labor cost of building 13½-ft. concrete steel sewer was as follows:

Labor placing anchor bars (1,500 lbs.):

1 man 1 day, at \$3.50.....	\$3.50
1 man 1 day, at \$1.75.....	1.75
1 man ½ day, at \$1.50.....	0.80

Placing 1,500 lbs. steel, at 0.4 cts.....\$6.05

Labor on concrete invert and side walls:

5 men mixing and wheeling, at \$1.75.....	\$ 8.75
1 man tamping	1.75
1 man carrying concrete	1.75
¾ man lowering concrete, at \$2.25.....	1.50

Labor, 13 cu. yds. concrete, at \$1.06.....\$13.75

Labor on shale brick lining (3 rings):

2 masons, at \$5.60.....	\$11.20
1 man mixing mortar.....	2.25
3 men wheeling sand, filling buckets and dumping at \$1.75..	5.25
$\frac{1}{2}$ man lowering materials, at \$2.25.....	0.75

Labor, 6.38 cu. yds. brick work, at \$3.05.....\$19.45

Labor on concrete arch:

1 man putting mortar lining on centers, 3 days, at \$1.75..	\$ 5.25
2 men mixing mortar, screening and wheeling sand, 3 days, at \$1.75	10.50
3 men on mixing board, 3 days, at \$1.75.....	42.00
1 man tamping, 3 days, at \$1.75.....	5.25

Labor, 72 cu. yds., at \$0.87.....\$62.00

Labor placing centers and steel skeleton:

1 man, 3 days, at \$3.50.....	\$10.50
2 men, 3 days, at \$1.75.....	10.50

Labor, 40 lin. ft., at 52 $\frac{1}{2}$ cts. per ft.....\$21.00

There were 56 lbs. of steel skeleton per lin. ft., and about $\frac{1}{2}$ the time of this last gang of 3 men was spent in placing the metal, $\frac{1}{2}$ being spent in moving and placing the centers; so the labor cost 0.3 cts. per lb. of steel (not including shop work) and the labor moving centers cost 35 cts. per lin. ft. of sewer. The backfilling was begun 6 to 12 hrs. after the arch was built, but the centers were left in place 14 days.

On another section of this sewer a six-day observation showed the labor cost (hand work, no machine mixers) was 81 cts. per cu. yd. of concrete in the invert and side walls, and 70 cts. per cu. yd. on the concrete in the arch; 36 cts. per lin. ft. for placing centers, and 18 cts. per lin. ft. for placing the steel skeleton; 0.22 cts. per lb. for placing the anchor rods. A gang of 2 brick masons and 6 laborers laid 11.2 cu. yds. of the double-ring brick lining per day, at a cost of \$2 per cu. yd. All wages were as above given. It will be seen that this longer observation gave much lower costs than above tabulated, and Mr. Parmley regards it as being nearer a fair average.

Cost of Reinforced Concrete Sewer, Wilmington, Del.—Mr. T. Chalkley Hatton, M. Am. Soc. C. E., gives the following data: Fig. 17 shows a profile of Price's Run Sewer, Wilmington, Del., built in 1903, by day labor for the city, the working day being 8 hrs. long. Fig. 18 shows cross-sections at different points. The notable feature is the boldness in the design of such thin concrete shells for sewers of such large diameters. The cross-sections of sewers in trenches deep enough to cover the arch are marked "deep cutting"; the sections where the arch projects above the ground surface are marked "light cutting." The section through the marsh was 700 ft. long, the cutting being 8 ft. deep, and at high tide the marsh was flooded 1 to 4 ft. The material was a soft mud that would pull a tight rubber boot from a workman's foot. The cost of this marsh excavation including cofferdams, underdraining, pumping, etc.,

was \$4.60 per cu. yd. For 1,100 ft. the 9¼-ft. sewer was through a cut 22 to 34 ft. deep, the material being clay underlaid by granite. A Carson-Lidgerwood cableway was used. Although the crown of the arch was but 8 ins. thick, it withstood the shock of dumping 1 cu. yd. buckets of earth and rock from heights of 8 to 10 ft.; and the weight of 25 ft. of loose filling caused no cracks in the concrete.

Concrete was placed in 4-in. layers (the depth of the lagging) and well rammed, since it was found that "wet" concrete left small honeycombed spaces on the inner surface. Concrete for the invert was 1:2:6, the stone being 1½-in. and smaller, and the sand being crusher dust. The arch was 1:2:6.

The reinforcing metal used in the 9¼-ft. sewer was No. 6 expanded metal, 6-in. mesh, in sheets 8 x 5½ ft., supplied by Merritt & Co., of Philadelphia. A single layer was placed around the

Fig. 17.—Profile of Sewer.

sewer, 2 ins. from the inner surface, its position being carefully maintained by the men ramming, and with but little difficulty as the sheets were first bent to the radius of the circle. Each sheet was lapped one mesh (6 ins.) over its neighbor at both ends and sides, and no sheets were wired except the top ones, which were liable to displacement by men walking over them.

The metal used on the rest of the work was a wire-woven fabric furnished by the Wight-Easton-Townsend Co., of New York. This fabric comes in rolls 5½ ft. wide and 100 ft. to the roll. The wire is No. 8, with a 4 x 4-in. mesh. This fabric was placed by first cutting the sheets to the required length to surround the sewer entirely, embedding it in the concrete as fast as concrete was placed, in the same manner as was done with the expanded metal, except over the center where, on account of its pliability, the fabric was held the proper distance from the lagging by a number of 2-in. blocks, which were removed as the concrete was placed. The wire cloth, being all in one sheet, can be placed a little more expeditiously than expanded metal, but, on the other hand, the

Section through Manhole

Fig. 18.—Cross Sections of Concrete Sewer.

expanded metal holds its position better in the concrete, since it is more rigid.

I quote now from Mr. Hatton's letter to me: "The major portion of concrete was mixed by machine at a cost of 46 cents per yard, including wheeling to place, coal and running of mixing machine, wages being \$1.50 per day of 8 hrs. Stone was delivered alongside of machine and all material had to be wheeled in barrows upon the platform, and after mixing to the sewer. Placing and ramming concrete around the forms cost 38 cts. per cu. yd., additional. Setting forms in invert cost 1 cts. per cu. yd. of invert; setting centers, 7 cts. per cu. yd. of arch. Cost of setting forms and centers includes placing steel metal. Each lineal foot of 2½-ft. sewer contained 1 cu. yd. of concrete, although the section only calls for 0.94 cu. yd. The excess was usually wasted by falling over sides of forms or being made too thick at crown.

"This yard of 1:2:5 concrete cost in place as follows (record taken as an average of several days' run):

Cement, 1.31 bbls., at \$1.30.....	\$1.703
Stone, 0.84 cu. yds., at \$1.21.....	1.016
Stone dust, 0.42 cu. yds., at \$1.21.....	0.508
Labor, at 18½ cts. per hour.....	0.987
Labor setting forms and setting metal.....	0.045
Cost of forms (distributed over 1,800 ft. of sewer).....	0.082
40 sq. ft. expanded metal, at 4½ cts.....	1.700
Labor plastering invert.....	0.070

Cost per lin. ft., or per cu. yd.....\$6.111

"The forms for the invert were made of 2-in. rough hemlock boards cut out 4 ins. less diameter than the diameter of the sewer, except for 18 ins. at the bottom of the form which coincided with the inside form of sewer. The bottom of the sewers was laid to the bottom of this form before it was set. Then the lagging, consisting of 2 x 8-in. x 16 ft. hemlock planed, was placed against each side of the form, one at a time, and the concrete brought to the line of this top in 6-in. layers until the whole invert was finished. These forms were set in 16 ft. sections, five to each section.

"The centers consisted of seven ribs of 2-in. hemlock upon which was nailed 1½-in. lagging, 2 ins. wide, tongued and grooved, and were 16 ft. long, non-collapsible, but had one wing on each side, 9 ins. wide, which could be wedged out to fit any inaccuracies in the invert. We used four of these centers setting two at each operation and worked from two ends. We left the centers in for 18 hours before drawing.

The cost of the concrete on the smaller sewers was the same as are the larger sewers, but the steel metal cost less, as it was wire woven metal that cost 2½ cts. per sq. ft. It was much easier handled and cut to no waste as it came in long rolls and was very pliable.

"After training our men, which occupied about one week or 10 days, we had no difficulty in getting the concrete well placed around the metal, preserving the proper location of the latter, which, how-

ever, bore constant watching, as a careless workman would often take the temporary supporting blocks and allow the metal to rest against the wooden center, in which case the metal would show through the surface inside of the sewer. The metal was kept 2 ins. away from the inside forms and the arch. To keep it at this location we had several 2-in. wooden blocks cut which were slipped under the wire or expanded metal and as soon as some concrete was pushed under the wire at this point the block was removed.

"After the forms were removed the invert needed plastering, but the arch was practically like a smoothly plastered wall except where it joined the invert, where it frequently showed the result of too much hurry in depositing the first loads of concrete on the arch. We remedied this by requiring less concrete to be deposited

Fig. 13.—Reinforced Concrete Sewer.

at the start, thus giving the rammers time to place the material properly.

"An interesting result was obtained in the smoothness of the inside surface by using a mixture of different sized stones. When $\frac{3}{4}$ -in. stones or smaller were used in the arch, the inside was honeycombed; but, where 1 to $1\frac{1}{2}$ -in. stones (nothing smaller) were used, the inside was perfectly smooth, and the same was true of the invert, showing that the use of larger stones is an advantage and secures more monolithic work. When the run of the crusher from $1\frac{1}{2}$ to $\frac{3}{4}$ -in. stones was used the work was not at all satisfactory.

"The difference in cost of mixing by hand and machine is practically nothing on this kind of work, as the moving of the machine to keep pace with the progress of the work equals the extra cost of mixing by hand when the mixing can be done close to the point where the cement is being placed."

The total cost of the sewers, including excavation, etc., was:

	Cost per lin. ft.
3½-ft. sewer through marsh.....	\$32.00
3½-ft. sewer in cut averaging 24½ ft.....	24.00
3½-ft. sewer in cut averaging 12 ft.....	10.00
5-ft. sewer in cut averaging 11½ ft.....	6.70

Cost of a Reinforced Concrete Sewer, Kalamazoo, Mich.—Mr. Geo. S. Pierson gives the following data:

A reinforced concrete sewer 1,080 ft. long at Kalamazoo, Mich., was begun Nov. 3, 1902, and finished Jan. 10, 1903. The work was done by day labor for the city. Much of the work was done at a temperature of 12° to 25°. The sewer arch has a span of 9 ft. 10 ins., and the sewer is 6 ft. high from invert to crown. The arch is 8 ins. thick at the crown, and the invert is 6 ins. thick, Fig. 19. The concrete was reinforced with woven-wire fabric of No. 11 steel wires. The concrete was 1 cement to 6 gravel and sand, but this proportion was not strictly adhered to. The centers were built in sections 12½ ft. long, and there were 6 arch sections and 13 invert sections. The ribs for the arch centers were of 2-in. pine, and were 2 ft. apart. The sheeting was 1-in. dressed white pine. The average gang was 10 men mixing and wheeling concrete, 5 men placing and ramming, and 4½ men moving and setting up forms. This gang averaged 18.6 lin. ft. of sewer per day, the best day's work being 28 lin. ft. There were 0.95 cu. yds. of concrete per lin. ft. of sewer. Wages were \$1.75 a day. The cost per lineal foot was as follows, including superintendence:

	Per lin. ft.	Per cu. yd.
1.18 bbls. cement	\$2.44	\$2.56
Sand and gravel.....	0.42	0.44
Labor mixing and wheeling (10 men)....	0.98	1.03
Labor placing and ramming (5 men)....	0.47	0.50
Labor moving and setting forms (4½ men) ..	0.42	0.45
Cost of forms and templates.....	0.30	0.32
Metal fabric (175 lin. ft. No. 11 wire)....	0.39	0.41
Finishing	0.09	0.10
Tools, general expenses and superintendence	0.43	0.45
Total	\$5.95	\$6.26

The cost of excavation and backfilling is not included

It will be noted that the cost of moving and setting the forms was unnecessarily high. Compare this cost of 45 cts. per cu. yd. with the 5 cts. per cu. yd., at Wilmington, Del., in the next case cited.

Cost of a Reinforced Concrete Sewer at South Bend, Ind.*—In building 2,464 ft. of 66-in. circular reinforced concrete sewer at South Bend, Ind., in 1906, the method of construction illustrated in Figs. 20, 21 and 22 was employed. The sewer has a 9-in. shell buttressed on the sides, and is reinforced every 12 ins. by a 3/16 x 1-in. peripheral bar in the sides and roof and 3 ins. in from the soffit.

**Engineering-Contracting*, Aug. 22, 1906.

Each bar is composed of three pieces, two side pieces from 15 ins. below to 6 ins. above springing lines and a connecting roof bar attached to the side bars by cotter pins. Two grades of concrete were used, a 1:3:6 bank gravel concrete for the invert and a 1:2:4 bank gravel concrete for the arch. The invert was given a $\frac{1}{2}$ -in. plaster coat of 1:1 mortar as high as the springing lines.

Forms and Concreting.—In constructing the sewer the trench was excavated so as to give a clearance of 1 ft. on each side and was

Fig. 20.—Concrete Sewer Construction.

Fig. 21.—Concrete Sewer Construction.

sheeted, as shown by Fig. 20. The sewer was built in 12 ft. sections as follows: The bottom of the trench was shaped as nearly as possible to the grade and shape of the base of the sewer. Four braces to each 12-ft. section were then nailed across the trench between the lowest rangers on the trench sheeting. A partial form consisting of a vertical row of lagging was set on each of the outside lines of the sewer barrel as shown by Fig. 20. Each section of this lagging was held by stakes driven into the trench bottom

and nailed at their tops to the cross braces, as shown by Fig. 21. A template for the invert was then suspended from the cross braces by pieces nailed to the four ribs of the template and to the cross braces, as shown by Fig. 20. The concrete was now placed and carried to the top of the template, which was then removed. The side pieces of the reinforcing bars were then set and fastened, as shown by Fig. 21. The side forms extending up to the springing lines were then placed. They were held in position by braces nailed to their ribs at the tops and by other braces fitting into notches in the ends of their ribs at the bottom. The concrete was then carried up to the springing lines; the arch centers in two pieces were placed; the arch bar of the reinforcement was placed, and the extrados forms erected up to the 45° lines, all as shown by Fig. 22. The placing of the arch concrete completed the sewer barrel. The outside forms and bracing were removed about 24

Fig. 22.—Concrete Sewer Construction.

hours after the completion of the arch, and backfilling the trench was begun immediately, but the inside forms were left in place for two weeks; they were then removed by the simple process of knocking out the notched braces. By building several lengths of invert first and following in succession by the side wall construction and then by the arch construction, the form erection and the concreting proceeded without interruption by each other. It was also found that, by making bends in the form of polygons with 10-ft. sides instead of in the form of curves, there was a material saving in expensive form work. To overcome the friction of the angles in such bends, an additional fall was provided at these places. All concrete was made in a Smith mixer mounted on trucks so that it could be moved along the bank of the trench and discharging into a trough leading to the work.

Labor Force and Cost.—With a gang of 12 men, from 24 to 36 ft. of sewer were built per 10-hour day, working only part of the

time on actual concreting. The disposition of the force mixing and laying concrete and the wages were as follows:

	Per day.
Six wheelers, at 18.5 cts. per hour.....	\$11.10
One mixer, at 22.5 cts. per hour.....	2.25
One dumper, at 18.5 cts. per hour.....	1.85
Four placers, at 22.5 cts. per hour.....	9.00
Total	\$24.20

There were 0.594 cu. yds. of concrete per lineal foot of sewer, and its cost is given as follows:

	Per cu. yd.
Gravel	\$8.774
Sand	0.85
Cement	1.50
Steel reinforcement	0.84
Labor, mixing and placing concrete.....	1.094
Moving forms, templates, etc.....	0.757
Forms, templates, etc.....	0.589
Finishing, plastering, etc.....	0.629
Tools and general expenses.....	0.841
Total	\$7.395

The work was done under the direction of Mr. A. H. Hammond, M. Am. Soc. C. E., City Engineer, South Bend, Ind., to whom we are indebted for the information given.

Cost of a Large Reinforced Concrete Sewer at St. Louis, Mo.*— An unusual piece of sewer work is being carried out by the city of St. Louis. Harlem Creek, which drains a large area of the city and which has been made the outlet of district sewers until it has become a menace to health, is being replaced by a large reinforced concrete intercepting sewer. Ultimately the sewer will be several miles long, but at present only 2,206 lin. ft. of the lower end are under construction and about as much more is planned for early contract. The sewer under construction comprises 162 ft. of 29-ft. section, and 1,340 ft. of 27-ft. section; the 162 ft. of 29-ft. section have been completed and the following is an account of the methods of construction adopted by the contractors, the Hoffman-Hogan Construction Co., of St. Louis, Mo., with a statement of the cost of the work.

The interior dimensions of the sewer are 29 x 18.62 ft., giving an area of opening of 411 sq. ft. The grade of the sewer is 0.0025 per cent, which gives a velocity running full of 18.9 ft. per second and a capacity of 7,489 cu. ft. per second. The estimated run-off, calculated by McMath's formula, is 100 cu. ft. per second less. The area drained is about 6,000 acres and the maximum rainfall assumed is 2.75 ins. per hour.

The cross-section of the sewer is given by Fig. 23, which also shows the arrangement of the reinforcing bars. Johnson corrugated bars, old style, are used for reinforcement. The sections of the various reinforcing bars are: Longitudinal bars, 0.18 sq. in.; invert bars, 0.7 sq. in.; and arch bars, 0.7 sq. in. The spacing of

**Engineering-Contracting*, Feb. 20, 1907.

the bars and the arrangement of the splices are indicated on the drawings of Fig. 23. All splices have a lap of 35 ins. Some gravel concrete has been used in the invert, but most of the concrete has been crushed limestone and Mississippi River channel sand. The proportions were 1:3:6 in the invert and 1:2:5 in the arch. The arch was computed by Prof. Greene's method. The ultimate strength of concrete in compression was taken as 2,000 lbs. per sq.

Fig. 23.—Reinforced Concrete Sewer.

in. and the working strength at 500 lbs. per sq. in. The elastic limit of the reinforcing bars was taken at 60,000 lbs.

The trenching was done by wheel scrapers to the amount of waste. Then a cableway was erected spanning the entire length of the section and the remainder of the material taken out. The last 4 or 5 ft. in depth were in limestone and the excavated rock was taken by cableway to dump carts which took it to the crusher and returned with crushed rock to be used for concrete. This rock foundation was taken advantage of to reduce the amount of invert concrete.

In constructing the sewer proper the invert was first concreted to template. The arch forms were then placed and the roof arch con-

creted. Both templates and arch forms were constructed of wood. The arch forms were moved ahead on iron rails and jacked into place. The ribs were 2 x 10-in. pieces and were spaced 4 ft. on centers; the lagging was 2-in. tongue and grooved stuff and was smeared with crude oil. The reinforcing bars were bent to proper radius by means of a wagon tire bender and were held in place by templates. The concrete was all mixed by two Chicago Improved Cube mixers operated by electric power.

The cost records of constructing the section of 29-ft. sewer so far built are not susceptible of complete analysis, but the following figures can be given. The prices of materials were as follows:

Cement, per barrel.....	\$ 1.80
Sand, per cubic yard.....	0.75
Broken stone, per cubic yard.....	1.00
Reinforcing bars, per pound.....	0.02
Vitrified brick, per 1,000.....	12.00

The wages paid different classes of labor were:

	Per hour.
Firemen	\$0.50
Laborers	0.175
Laborers	0.20
Laborers	0.25
Laborers	0.28
Laborers	0.3025
Bricklayers	0.66%
Helpers	0.25
Carpenters	0.55
Engineers	0.50
Timekeepers	0.25
Watchmen	0.175
Hostlers	0.175
Teams	0.60

Taking up the several items of work in order, the excavation amounted to 21,400 cu. yds., of which 1,400 cu. yds. were rock excavation. The cost of excavation was as follows:

	Total.	Per cu. yd.
Earth, excavation	\$7,640	\$0.38
Earth, bracing	2,000	0.10
Rock, excavation	1,400	1.00
Rock, dynamite, tools, etc.....	560	0.40

The cost of crushing the excavated rock and returning it to the mixer was \$1 per cu. yd.

The cost of the concrete work was as follows:

	Per cu. yd.
1.80 bbl. cement, at \$1.80.....	\$2.24
0.44 cu. yd. sand, at 75 cts.....	0.33
1 cu. yd. broken stone, at \$1....	1.00
Total concrete materials.....	\$3.67

There were 1,600 cu. yds. of concrete placed at a cost of for:

	Total.	Per cu. yd.
Mixing and placing.....	\$1,180	\$0.7375
Forms	2,000	1.25
Moving forms	400	0.25
Total for forms and labor....	\$3,580	\$2.2375

For reinforcing the concrete 86,600 lbs. of steel, or about 55 lbs. per cu. yd., were used. The cost of placing and bending this steel was as follows:

	Total	Per lb.
Placing	\$172	0.20 ct.
Bending	52	0.06 ct.

We can now summarize the cost of the concrete work proper of this sewer as follows:

	Per cu. yd.
Cement, sand and stone.....	\$3.67
55 lbs. steel, at 2 cts.....	1.10
Forms, labor and materials.....	1.25
Mixing and placing concrete labor.....	0.74
Placing steel, at 0.20 ct. per lb.....	0.11
Bending steel, at 0.06 ct. per lb.....	0.03
Moving forms	0.25
Total labor and materials.....	\$7.15

Fig. 24.—Reinforced Concrete Sewer.

To get the total cost of the sewer proper we must add the cost of the vitrified brick invert paving. There were 71 cu. yds. of this paving and its cost was as follows:

	Per cu. yd.
0.6 bbls. cement, at \$1.80.....	\$1.08
0.25 cu. yd. sand, at 75 cts.....	0.19
450 bricks, at \$12 per M.....	5.40
Labor laying, 71 cu. yds., at \$180.22.....	2.54
Total	\$9.21

None of the preceding figures include the plant charges. The plant cost \$12,000, and the cost of running it during the work described was \$2,000. This plant will, of course, serve for the whole work under contract.

Cost of a Reinforced Concrete Sewer.—Mr. Wm. G. Taylor is authority for the following data.

The sewer had the section shown by Fig. 24; it was constructed

of 1:7½ concrete mixed to a mushy consistency using the forms shown by the illustration. The reinforcement was of twisted steel rods for parts of the work and of expanded metals for parts. When rod reinforcement was used it was bent on the bank and erected in cage form in the trench. The invert section was built as the first operation and the forms erected on it. The first cost of the forms shown was \$1.80 per lin. ft. of sewer and the cost of maintenance was about 12 cts. per lin. ft., including depreciation and fixed charges. Petrolina was used to grease the forms and was found superior to soft soap or to both light and dark mineral oils which were also tried. The concrete was deposited in level layers 6 ins. thick. The normal cost per lineal foot and per cubic yard of the sewer was as follows:

Materials:	Per lin. ft.	Per cu. yd.
Reinforcement (17½ lbs. per lin. ft.).....	\$0.43	\$1.16
Cement (0.482 bbl. per lin. ft.), at \$1.53..	0.74	2.00
Sand (0.17 cu. yd. per lin. ft.), at \$0.50..	0.09	0.24
Stone (0.425 cu. yd. per lin. ft.), at \$1.10		
per ton	0.47	1.27
Total	\$1.73	\$4.67
Labor:		
Making and placing reinforcement.....	\$0.14	\$0.38
Operation of forms.....	0.16	0.42
Mixing concrete	0.30	0.81
Placing concrete	0.27	0.73
Screeding and finishing invert.....	0.08	0.22
Finishing interior surface.....	0.01	0.03
Sprinkling and wetting.....	0.03	0.06
Total	\$0.98	\$2.66
General charges:		
Interior forms, cons. and maint.....	\$0.13	\$0.33
Exterior forms, cons. and maint.....	0.05	0.14
Coating oil for forms.....	0.01	0.03
Cement, storage, handling and cartage....	0.08	0.22
Total	\$0.26	\$0.71
Grand total.....	\$2.97	\$8.04

In reference to these figures it should be noted that, as several contractors did the work, these are the composite costs. They include a foreman at 50 cts., a sub-foreman at 35 cts., common labor at 17½ cts., and teams at 50 cts. per hour. No administration expenses or contractor's profit are included.

Cost of Concrete Sewers, Richmond, Ind.—From a long and instructive article by Mr. Fred R. Charles, in *Engineering-Contracting*, Dec. 29, 1909, the following is an abstract:

Concrete Pipes.—Fifty-two-inch was the largest size used in concrete pipe. This was made according to the "Sheets" system, in which expanded metal is used for reinforcement; thickness of shell is 1 1/12 ins. per foot diameter; 24 ins. pipe made in 2½ ft., and larger sizes in 3-ft. lengths. Pipe is made in a mold consisting of an outer steel casing and an inner collapsible shell. The pipe rests on the end upon a pallet, and each end is formed by a shaping

ring, so that it is notched or rabbeted through half the thickness of the shell, on the outside for one-half the circumference, and on the inside for the other half circumference. The pipes are laid so as to form a groove at the joint, coming on the interior for the lower half and on the exterior of the upper half, whereby the mortar is always plastered downward in cementing the joint. For handling and placing in the trench a tripod or beam derrick is needed with a block and tackle or chain hoist, as the weight is considerable. Our average cost to lay these pipes, including plastering the joints, was for 42-in., \$0.083; 30-in., \$0.06; 24-in., \$0.053 per lin. ft.

Monolithic Concrete.—Another sewer, 34 ins. in diameter, was built in horse-shoe shape, semi-circular arch, vertical sides and bottom slightly V shaped. It was in an open ditch or water course, so nearly all except the flow line was above ground, and outside forms were necessary, in the absence of the trench walls, to hold the concrete. First the bottom was laid as in sidewalks, and the vertical sides run up to the spring line with ordinary plank inner and outer forms, the expanded metal reinforcement having been bent and placed as before, with plenty of lap at the spring line. The arch was put on with a semi-circular "Blaw" form. On all these monolithic jobs the average labor hours per linear foot for the different operations of constructing the sewer, using "Blaw" forms and expanded metal reinforcement, is given in the following table. Knowing the wages paid labor per hour and the price of materials, this will be some guide to the cost in other places:

	Labor hours per lin. ft.
Placing flow line.....	0.48
Setting invert forms.....	0.50
Concreting invert.....	0.44
Setting arch forms.....	0.33
Concreting arch.....	0.25

For the lower half of the sewer the concrete should be very wet, so that it will flow freely around and under the forms; for the arch not so much water must be used; only enough to show quite perceptibly when concrete is tamped, as the concrete must have sufficient consistency to retain its position and not run off the arch; for the flow line the proper consistency is between the two. At first, house connections were provided for by building in ordinary vitrified sumps or thimbles, but the flanges of these were frequently broken by falling rock and otherwise, so a change was made and an opening left in the concrete shell by means of a special form or core, devised by Mr. D. B. Davis, inspector on the work. This comprised two circular blocks of hard wood, nailed together; one 8 ins. in diameter and 3 ins. thick, the other 6 ins. in diameter and 3 ins. thick. Inserted in the concrete this left a good flange to receive the end of the 6-in. house connection pipe, and was extremely inexpensive, two of these blocks lasting for the whole season. The average cost of this work was as follows:

For 54-in. sewer, 5-in. shell, rib metal 10 ft.:

	Per lin. ft.
Cement, 0.347 bbl. at \$1.25.....	\$0.434
Gravel at \$0.80.....	0.260
Rib metal.....	0.30
Forms (cost of).....	0.125
Labor, 20 cts. per hour.....	0.230

Total cost, exclusive of machine and superintendence\$1.349

For 48-in. sewer, 5-in. shell, rib metal 9 ft.:

Cement, 0.29 bbl. at \$1.25.....	\$0.362
Gravel at \$0.80.....	0.170
Rib metal.....	0.25
Forms.....	0.115
Labor, 20 cts. per hour.....	0.186

Total\$1.093

For 42-in. sewer, 4-in. shell, rib metal 8 ft.:

Cement, 0.20 bbl. at \$1.25.....	\$0.25
Gravel at \$0.80.....	0.118
Rib metal.....	0.24
Forms.....	0.115
Labor at 20 cts. per hour.....	0.188

Total cost, exclusive of machine and superintendence\$0.911

Forms were made by the Adjustable Steel Centering Co., 6 ft. long, and 6 sections were used, which make 36 ft. of sewer, allowing for the necessary lap. These forms are especially well adapted to large sewer work, owing to the accessibility of all the parts, which renders them easy and inexpensive to handle. They are made of sheet steel with steel ribs on the inside at each end. These ribs are collapsed by especially made "collapseers"; forms then set in place.

Cost of Making Blocks for a Concrete Sewer.—At Coldwater, Mich., in 1901, there was built a concrete sewer with a monolithic invert and an arch of concrete blocks. Riggs & Sheridan, of Toledo, O., designed the sewer, and H. V. Gifford, of Bradner, O., was in charge of construction.

The sewer was circular, having an inner diameter of 42 ins., the thickness of the invert and the arch alike was 8 ins. The concrete was 1 of Portland cement to 6 of gravel. There were 11 concrete blocks in the ring of the arch, each block being 24 ins. long, 8 ins. thick, 8 ins. wide on the outside of the arch and 5½ ins. wide on the inside of the arch. A block weighed 90 lbs. which was too heavy for rapid laying; blocks 18 ins. long would have been better. Some 8,500 blocks were made. Molds were of 2-in. lumber, lined with tin, for after a little use it was found the concrete would stick to the wood when the mold was removed. The four sides of the mold formed the extrados, the intrados, and the two ends of the block; the other two sides being left open. When put together the mold was laid upon a 1-in. board, 12 x 30 ins., reinforced by cleats across the bottom. The sides of the molds were held to-

gether with screws or wedge clamps. When the blocks had set, the sides of the molds were removed, and the blocks were left on the 12 x 30-in. boards for 3 days, then piled up, being watered several times each day for a week.

A gang of 14 men made the blocks; 2 screening gravel through 1-in. mesh screen; 4 mixing concrete; 4 molders; 3 shifting and watering blocks; and 1 foreman. With a little practice each molder could turn out 175 blocks a day; and since each block measured $\frac{3}{4}$ cu. ft., the output of the 14 men was $19\frac{1}{2}$ cu. yds. a day. Mr. Gifford informs me that the wages were \$1.50 a day for all the men, except the foreman. The daily wages of the 14 men were \$22, so that the labor of making the blocks was \$1.10 per cu. yd.

Each batch of concrete, containing $\frac{1}{2}$ bbl. of Portland cement costing \$1.35 per bbl., made 18 blocks. (1 bbl. per cu. yd.) Since the gravel cost nothing, except the labor of screening it, the total cost of each block was 11 to 12 cts., which includes 0.85 cent for use of molds and mold boards, which were an entire loss. At 12 cts. per block the cost was \$4.32 per cu. yd.

The contract price was \$3 per lin. ft. of this sewer, as against a bid of \$3.40 per ft. for a brick sewer.

When the trenching had reached to the level of the top of the invert, two rows of stakes were driven in the bottom, stakes being 6 ft. apart in each row, and rows being a distance apart $\frac{1}{4}$ -in. greater than the outer diameter of the sewer. These stakes were driven to such a grade that the top of a 2 x 4-in. cap or "runner" set edgewise on top of them was at the proper grade of the top of the invert. The excavation for the invert was then begun and finished to the proper curve by the aid of a templet drawn along the 2 x 4-in. runners. In gravel it was impossible to hold the true curve of the invert bottom. Concrete was then placed for the invert. To hold up the sides of the invert concrete, a board served as a support for the insides, but regular forms were more satisfactory in every respect except that they were in the way of the workmen. A form was tried, its length being 6 ft. It was built like the center for an arch, except that the sheeting was omitted on the lower part of the invert. It was suspended from cross-pieces resting on the "runners." After the concrete had been rounded in place, the form was removed and the invert trued up. This form worked well in soil that could be excavated a number of feet ahead, so that the forms could be drawn ahead instead of having to be lifted out; but in soil, where the concreting must immediately follow the excavation for the invert, the form is in the way. The invert was trued up by drawing along the runners a semicircular templet having a radius of $21\frac{1}{2}$ ins. Then a $\frac{1}{2}$ -in. coat of 1:2 mortar was roughly troweled on the green concrete. Another templet having a 21-in. radius was then drawn along the runners to finish the invert.

When the plaster had hardened, two courses of concrete blocks were laid on each shoulder of the invert, using a 7:2: $\frac{1}{4}$ mortar,

the $\frac{1}{4}$ part being lime paste. The lime made the mortar more plastic and easier to trowel. Then the form for the arch was placed, and as each 8-ft section of the arch was built, a grout of 1:1 mortar was poured over the top to fill the joints. Earth was thrown on each shoulder and tamped, and the center moved ahead.

Common laborers were used for all the invert work, except the plastering, which was done by masons who were paid 30 cts. per hr. Masons were also used to lay the concrete blocks in the arch. Mr. Gifford states that two masons would lay at the rate of 100 lin. ft. of arch per day, if enough invert were prepared in advance. As there were 11 blocks in the ring of the arch, this rate would be equivalent to $7\frac{1}{2}$ cu. yds. of arch laid per mason per day.

Cost of Concrete Sewer Blocks.—The cost of molding several thousand concrete blocks to be used in sewer construction at Halifax, N. S., is given in the "Canadian Engineer," from which we rearrange and further analyze the figures as follows:

The work involved the mixing and molding of 356.35 cu. yds. of concrete in 1,341 batches of 7.17 cu. ft. each. The cost of the molded blocks was as follows:

	Total.	Per cu. ft.
5,050 hrs. labor, at 15 to 24 cts.	\$ 838.76	\$0.087
1,783 bushels cement, at 80 cts.	1,386.40	0.144
2,850 bushels sand, at 6 cts.	171.00	0.017
2,684 bushels gravel, at 6 cts.	141.04	0.014
5,364 bushels stone, at 7 cts.	375.48	0.038
Paper	26.82	0.0028
Soap	17.85	0.0018
Coal	48.95	0.0050
Total	\$3,006.30	\$0.3096

The cost of the blocks complete was thus 31 cts. per cu. ft. or \$8.37 per cu. yd. This cost includes cleaning molds, moving and storing blocks and all expenses incident to the cost of manufacture except the cost of the water used.

Cost of Concrete Block Manholes.—Mr. Hugh C. Baker, Jr., gives the following:

The cost of making concrete block manholes at Rye, N. Y., was as follows per manhole:

30 blocks for walls, 2.5 cu. yd. of 1:2:5 concrete....	\$21.00
6 blocks for cover, $\frac{1}{2}$ cu. yd. reinforced concrete...	4.27
I-beams for cover in place.....	5.40
Supervision, freight and hauling, 5.6 tons concrete..	9.38
3 hrs. labor placing cover, at 15 cts.....	0.45
20 hrs. labor placing walls, at 15 cts.....	3.00

Total per manhole, exclusive of iron cover....\$43.50

Each manhole was 5 ft. deep inside, 8-in. walls, 5 ft. in diameter. All concrete was hand-mixed, very wet, $\frac{3}{4}$ -in. stone being used. A set of 30 wooden molds for the wall blocks was made. These molds cost from \$3.50 to \$12 each; some being made of hard wood lined with zinc. In making the blocks 4 men averaged 15 wall blocks a day of about $2\frac{1}{2}$ cu. ft. each, which is equivalent to 0.84 cu. yd. per man per day. The concrete was allowed to set 8 to 12

hrs. before removing the molds; 24 to 36 hrs. before taking the blocks outside to dry, and 7 days before shipping the blocks. About 1,000 blocks were made and only 9 lost by breaking.

For comparison it is well to give the cost of brick manholes, as follows:

1,460 brick, at \$8.25 per M.....	\$11.96
Mason	6.00
46 hrs. labor, at 15 cts.....	6.90
4 bbls. cement, at \$1.25.....	5.00
Sand75
Supervision, etc.	2.50
Concrete top blocks ($\frac{1}{2}$ cu. yd.) and I-beams.....	11.40
Total	\$44.51

This brick manhole had a flat concrete top.

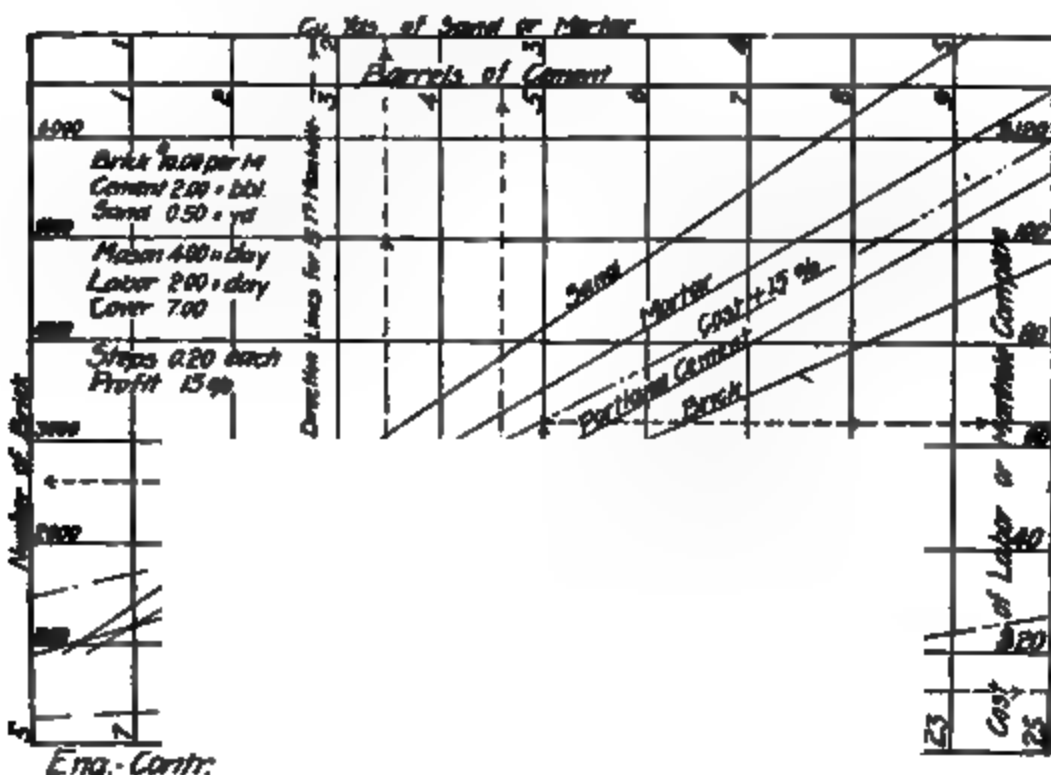

Fig. 25.—Diagram for Estimating Quantities in and Costs of Manholes.

Estimating the Cost of Manholes from a Diagram.—This diagram and the description of its use were given by Mr. John Wilson, in *Engineering-Contracting*, Dec. 8, 1908.

Herewith is given a diagram (Fig. 25) for estimating the quantities of materials in manholes; and, at given prices of materials and labor, the cost of the manhole can likewise be ascertained. The diagram shown is for a 4-ft. manhole.

Having the depth of the manhole given, the number of brick, the amount of sand, cement, mortar, the cost of labor, and total cost of manhole complete, plus 15 per cent profit, may be taken from the diagram.

Thus for a 15-ft. manhole, follow the vertical 15-ft. line to inter-

section with brick curve, thence horizontally to left read 2,606. From the intersections of the last horizontal line with the sand, mortar and cement curves, respectively, read vertically above 1.88 cu. yds. of sand, 2.22 cu. yds. of mortar and 4.6 barrels of cement. To ascertain the cost, follow the vertical 15-ft. line from bottom to intersection with the cost curves, and read horizontally to right, cost plus 15 per cent, \$64, of which the cost of labor alone is \$12.50, as shown by the labor curve.

The curves allow for a double layer of brick in the bottom and the outside of the manhole to be well plastered. It is an easy matter to draw similar curves to meet local conditions and thus secure a very ready method of making estimates.

A Device for Building Circular Manholes.*—We illustrate here-with a device (Fig. 26) for use in building circular manholes having a concrete bottom and brick walls. The device was designed

Fig. 26.—Device Used in Building a Manhole.

by Mr. Elmer E. Barnard, Assistant City Engineer of Lynchburg, Va., and has been in use in the sewer department of that city for about a year.

While the device was put in service with the primary object of getting a better class of work, yet both this has been obtained and the cost of the work has also been decreased quite a good deal.

Mr. Barnard informs us that, using the device, they have built two 10-ft. manholes in $2\frac{1}{4}$ days, two men at \$1.40 per day each, and one man at \$2.00 being employed.

Hence the labor cost of each manhole was:

$2\frac{1}{4}$ days, at \$1.40.....	\$3.15
$1\frac{1}{2}$ day, at \$2.00.....	2.25
Total	\$5.40

**Engineering-Contracting*, Sept. 19, 1906.

It has been found that on a system where a large number of manholes are to be installed, they can be built in much less time than the figures given above, owing to the fact that the concrete bottoms can be put in before the bricklayers have gotten up to the work.

Cost of a Concrete Manhole.—The following figures of the cost of constructing a concrete manhole are rearranged from the "Canadian Engineer." The construction of the manhole is clearly shown by the accompanying sketch (Fig. 27). About the only point that need be noted is that the form lumber was so cut up that it could not be used again and its total cost is therefore charged against the

Fig. 27 Concrete Manhole.

work. The costs were as follows, there being 4.08 cu. yds. of concrete in the manhole:

Materials:	Total.	Per cu. yd.
300 ft. B. M. lumber, at \$30.....	\$ 9.00	\$ 2.21
5 bbis. cement, at \$2.25.....	11.00	2.69
4 cu. yds. sand and gravel, at \$1. 4.00	4.00	0.98
Total materials	\$24.00	\$ 5.88
Labor:		
Forms, 70 hrs., at 32½ cts.....	\$22.75	\$ 5.57
Mixing and placing concrete:		
13 hrs., at 22½ cts.....	\$ 2.92	\$ 0.71
Total labor	\$25.67	\$ 6.28
Total labor and materials....	\$49.67	\$12.16

Cost of Brick Manholes.—The walls of brick manholes are generally 8 ins. thick up to 12 ft. in depth, and 12 ins. thick below. The cross-section of manholes is usually elliptical, 3 ft. x 4½ ft., up to the neck of the manhole which is circular and narrows down to about 24 ins. in diameter. The cast-iron ring and cast-iron cover weigh from 875 lbs. to 650 lbs., the lighter weight being used in village streets. A common weight for use in cities is 475 lbs. These "manhole heads" are carried in stock by manufacturers of sewer

pipe, and are listed in their catalogues. The following is the actual cost of a manhole built by day labor for a Western city:

2,000 brick, at \$6.....	\$12.00
475-lb. ring and cover, at 2 cts.....	9.50
2½ bbls. Louisville cement, at 75 cts.....	2.00
1 cu. yd. sand	1.50
24 hrs. bricklayer, at 55 cts.....	13.20
24 hrs. helper, at 18½ cts.....	4.50
Total	\$42.70

It will be noted that the mason averaged less than 700 bricks per 8-hr. day, which indicates that he realized that he was working for a city and not for an individual. However, small jobs like manhole work are apt not to be handled with rapidity. Consult, for comparison, other data. See "Manhole" and "Vault" in the index.

Cost of a Brick Manhole, Flush Tank and Laying Pipe Sewer.*—The following data relate to the construction of a brick manhole, a brick flush tank, and the laying of a section of sanitary sewer at Columbus, Mass. The work was constructed by day labor.

Brick Manhole.—The manhole was 4 ft. in diameter and 5½ ft. deep; it was of the "churn pattern." Its cost was as follows:

1,000 hard brick, at \$6.50	\$ 6.50
7 sacks Portland cement, at 50c.....	3.50
1 cu. yd. sand, delivered	0.86
Ring and cover, 395 lbs., at \$2.40 per 100 lbs.....	9.48
3 step irons.....	0.30
Hauling iron	0.20
Digging hole—in brick clay.....	2.25
Filling	0.76
Mason, 8 hours, at 55 cts.....	4.40
Helper, 8 hours, at 12½ cts.....	1.00

Total actual cost.....	\$29.23
Engineers' estimate of cost.....	\$30.00

Brick Flush Tank.—The flush tank was 4 ft. in diameter by 5 ft. deep. Its cost was as follows:

650 brick, at \$6.50.....	\$ 4.23
9 sacks Portland cement, at 50 cts.....	4.50
1 load sand50
1 load gravel60
Ring and cover, 395 lbs., at \$2.40 per 100 lbs.....	9.48
5-in. automatic syphon.....	22.10
Freight65
Drayage45
Drain pipe50
Digging and filling (sand).....	1.50
Mason, 9 hours, at 55 cts.....	4.95
Helper, 9 hours, at 12½ cts.....	1.13

Total actual cost.....	\$50.58
Engineer's estimate of cost.....	\$50.00

Laying Sewer.—The sewer was 1,613 ft. long, of 8-in. terra cotta pipe. The sewer pipe was furnished by the city, delivered on the job, so that the following is the cost of laying only.

Four manholes and one flush tank were also constructed, but these were paid for separately and their cost is not included in the

*Engineering-Contracting, June 9, 1909.

figures below. The average depth of the trench was $3\frac{1}{2}$ ft. The work was completed in 14 days of 10 hours each. The cost was as follows:

	Total.	Per lin. ft.
Labor, 1,639 $\frac{1}{2}$ hours, opening trench, laying and backfilling with shovels, at 10 cts. per hour	\$163.95	\$0.1016
Wiping joints (acting foreman), 143 hours, at 15 cts.	21.45	.0133
Superintendence, 14 days, at \$5.	70.00	.0434
Cement, 13 sacks, at 50 cts.	6.00	.0037
Sand, 3 loads, at 50 cts.	1.50	.0010
Total	\$262.90	\$0.163

We are indebted to Charles Lyon Wood, C. E., Columbus, Mass., for the above information.

Cost of Making Cement Pipe.—Mr. Arthur S. Bent gives the following data: In 1892 four miles of 28-in. cement pipe were laid for an irrigation system in Riverside county, California. The mortar was mixed by hand in boxes holding $\frac{1}{2}$ cu. yd., and was hoed over 3 times dry and 3 times wet. It was then tamped (17-lb. tampers) by hand into sheet iron molds.

The pipe was 28 ins. in diameter, $2\frac{1}{4}$ ins. thick and in 2-ft. lengths. The mixture used was 1 part Portland cement and $3\frac{1}{4}$ parts pit gravel and sand. During the best week's work, a gang of 25 men made 1 mile of pipe, or 25 ft. per man per day, or $1\frac{1}{4}$ cu. yds. of concrete per man per day. But the average week's work was $\frac{1}{2}$ mile of pipe made by a gang of 25 men, or 17 lin. ft., or 0.9 cu. yd. per man per day. The laborers received \$2 and upward per day.

This pipe line, after seven years of use, showed no appreciable loss of water in its 4 miles of length.

The Miracle Pressed Stone Co., of Minneapolis, Minn., manufacture molds for making cement tile and cement sewer pipe with bell ends. Their catalogue contains the data given in the following table:

COST OF CEMENT PIPE, IN 2-FT. LENGTHS.

(Mortar, 1:3 mixture; sand, 75 cts. per cu. yd.; cement, \$2 per bbl.; labor, \$2 per day.)

—Pipe, 2 ft. long.—

Kind of pipe.	Thick- ness.	Cu. ft. of sand.	Cost of sand.	Cost of cement.	Cost of labor.	Tot. cost 2-ft. pipe.	Total cost per ft.
24" Bell-End...	2"	2.75	\$0.075	\$0.460	\$0.15	\$0.685	\$0.34

Cost of Cement Pipe Sewer and Manholes at Brooklyn, N. Y.—The following records of the methods and cost of constructing a 24-in. egg-shaped cement pipe sewer in Butler street, Brooklyn, N. Y., were furnished by Mr. J. J. B. LaMarsh and published in *Engineering-Contracting*, Oct. 3, 1906. A plan and profile of the sewer are shown in Fig. 28., which gives all lengths. The work included trenching, pipe-laying and backfilling, manhole construction and catch basin construction.

The trench had an average depth of 12 ft. and was opened 3 ft. wide throughout. For the first 2 ft. the soil was loam and for the remainder of the depth it was gravel and sand. Picks were used. The timbering consisted of $1\frac{1}{2}$ x 12-in. vertical sheeting held by 2 x 10-in x 16-ft. rangers and 4-in. diameter bars 3 ft. long.

Fig. 28.—Plan and Profile of Sewer.

The sheeting was easily placed, as the bank stood until dried by the sun. On the 18-in. pipe curve into Rogers avenue the sheeting was left in place, but all the other timbering was removed.

The pipe was laid on a foundation plank $1\frac{1}{2}$ x 12 ins. It was cement pipe manufactured by the Wilson & Baillie Mfg. Co., and was of the general form shown by Fig. 29. It came in 3-ft. lengths, weighing for the 24-in. size 500 lbs. each. It was laid with a three-leg derrick, using a goose-neck to lower. Four men handled the pipe to the derrick and lowered it and two men in the bottom of the trench placed it. There was no separate pipe gang, the work being done by men taken from the trenching gang and in stretches of from 3 to 20 lengths, as the progress of work necessitated. In all 933 ft. of 24-in. pipe were actually laid, although the contractor got paid for 964 ft.; the difference of 31 ft. was taken up in the

3 x 6-ft. manholes. Besides the 24-in. pipe main, there were 36 ft. of 18-in. pipe, 32 ft. of 12-in. pipe, 10 manholes and 3 sewer basins.

Turning now to the cost of this work we have the following figures:

Amounts and Cost of Materials Used.

18,500 brick, at \$8.75	\$ 161.875
27 barrels of cement, at \$1.35	36.450
10 manhole heads and covers, at \$11.00	110.000
5,500 ft. B. M. lumber, at \$18.50	46.750
3 sets granite stones for basins, at \$35	105.000
3 sets blue stones for basins, at \$5	15.000
3 pans and hoods, at \$9.50	28.500
333 ft. 24-in pipe, at \$1.43	1,334.190
36 ft. 18-in. pipe, at \$0.85	30.600
32 ft. 12-in. pipe, at \$0.40	38.400
Total cost of materials.....	\$1,906.765

Fig. 29.—Cement Pipe for Sewer.

Owing to the method of doing the work the labor costs can be only partially classified. The trenching, sheeting, pipe-laying and backfilling were all done by the same gang, the men changing from one item to another, as occasion demanded. As a rule, the whole gang was worked on backfilling from 4:30 to 6 p. m. each day; there was no ramming.

Of the 5,500 ft. B. M. of lumber, the contractor got paid for

2,250 ft. B. M., leaving 2,250 ft. B. M. lost from use. In this connection it should be noted that about 40 loads of sand from the excavation were sold by the contractor at 25 cts. a load, or a total of \$10.

The team work was mostly hauling brick and lumber; the outfit was owned by the contractor and with driver was estimated to cost \$2.50 per day. The labor thus is itemized as follows:

Trenching, Pipe-laying, Timbering and Backfilling.

	Total.	Per lin. ft. Cts.
One foreman, 34 days, at \$3.50.....	\$119.000	11.90
One boy, 317 days, at 75 cts.....	23.775	2.37
One bracer, 34 days, at \$2.40.....	81.600	8.16
Labor, A, 172.5 days, at \$1.70.....	293.250	29.32
Labor, B, 192.9 days, at \$1.60.....	308.640	30.86
Team and driver, 12 days, at \$3.50....	42.000	4.20
Total	\$868.265	86.82

These figures per foot are based on 1,002 ft. of sewer, namely, 923 ft. 24-in., 36 ft. 18-in., and 33 ft. 12-in. sewer. They include labor, excavating and backfilling, manholes and basins, but not the mason's labor. With a trench 3 ft. wide and 12 ft. deep, there were 1.33 cu. yds. of trench excavation per lin. ft.; hence the excavation cost 65 cts. per cu. yd.

The labor for ten manholes and three basins was as follows:

Mason, 12.4 days, at \$7.....	\$ 86.80
Mason's helper, 12.4 days, at \$2.10.....	26.04
Total	\$112.84

The actual cost of one sewer basin was as follows:

Sewer Basin.

Materials:	
1 set granite	\$35.00
1 set bluestone	5.00
1 hood and pans.....	9.50
2,100 brick, at \$8.50.....	17.85
8 barrels cement, at \$1.25.....	4.05
21 ft. 12-in. pipe, at 40 cts.....	8.40

Total materials \$79.80

Labor:

6 men, 1 day, excavating and backfilling, at \$1.70....	\$ 3.50
1 mason, 1 day, at \$7.....	7.00
1 helper, 1 day, at \$2.10.....	2.10

Total labor \$17.60

Grand total \$97.40

The manholes were 3 x 4 ft. of brick masonry. The actual cost of one manhole was as follows:

Manhole.

1 head and cover.....	\$11.00
1,600 brick, at \$8.50.....	13.60
1½ barrels cement, at \$1.25.....	2.03
1 day mason, at \$7.....	7.00
1 day helper, at \$2.10.....	2.10

Total \$35.73

From the preceding figures the total cost of the work may be summarized as follows:

Materials	\$1,906.765
Labor	981.105
Total	\$2,887.870
Deduct sand	10.000
Total	\$2,877.870

In this total there is no wear on tools, interest on money invested, oil for 10 lanterns, or payment on bond included. There was no insurance on men.

Cost of Constructing Cement Pipe in Place.*—The method of making cement pipe in place, which will be briefly described in this article, is an invention of Mr. Ernest L. Ransome.

A short stretch of 8-in. pipe was built at the rate of 1 lin. ft. per minute by six men and a foreman. The men were working with great energy, and the records show that they actually averaged about half this rate, their average being 300 lin. ft. per 10-hr. day.

As shown in Fig. 30, three men work in the trench, one of the men packing the cement mortar in the mold, one continuously pulling the mold ahead by means of the lever and the third filling around the green pipe with earth. The other three men mix mortar and deliver it into the trench.

Before giving the cost of this pipe, a word as to the method of construction:

The mold, Fig. 31, is made of sheet steel with an inner core 10 ft. long. The front end of this core is surrounded by a short steel shell that serves as the outer form for the cement pipe. The mortar for the pipe is packed in between the inner core and this outer shell by a man who uses a small wooden rammer for the purpose as shown in Fig. 30. The man standing in the foreground keeps moving the mold forward slowly by means of the lever grasped in the right hand. This lever is provided with a dog that works in a ratchet and thus rotates a small drum upon which a wire rope is wound. The wire rope is anchored into a deadman in the trench ahead. As the mold is thus moved forward it leaves behind it the cement pipe which is still green. The cement mortar, however, is mixed with a small amount of water so that it possesses sufficient cohesion to hold together when unsupported by the core. To protect the pipe until it hardens, it has been found advisable to pack a little earth around its sides and over the top; this is done by the third man in the trench, and he does this backfilling upon the part of the pipe that is still supported by the core.

In verbally describing this feature of the construction two questions have invariably been asked:

1. Doesn't the pipe cave in occasionally, especially when it is of large diameter?
2. How are branches put in?

**Engineering-Contracting*, March, 1906.

Fig. 30.—Ransome Cement Pipe Mold in Trench.

Answering the first question, Mr. Ransome says that caving does not occur except when some heavy object falls upon the pipe before the cement has hardened. The pipe does not break down of its own weight even when made three feet in diameter.

To put in a branch a hole is cut in the side of the "green" pipe before the core has been pulled ahead. A branch of the proper pattern is shoved up tightly against the pipe and the collar of the branch is plastered with cement mortar, producing a strong water-tight joint.

The following was the itemized cost of an 8-in. cement pipe, built as before described, at Despatch, N. Y.:

6 men, at \$1.70 per day, 10 hours.....	\$10.20
1 foreman	2.00
3 bbls. cement, at \$1.25.....	3.75
2.3 cu. yds. sand, at 85 cts.....	1.80
Water16
Total for 300 lin. ft.....	\$19.90

Fig. 31.—Ransome Cement Pipe Mold.

This is equivalent to 6.63 cts. per lin. ft. of pipe. It should be added that the shell of this particular 8-in. cement pipe was made unusually heavy, being $1\frac{1}{2}$ ins. thick.

On another stretch of 12-in. pipe the cost was as follows:

	Per day.
7 men, at \$1.70.....	\$11.90
1 foreman	2.20
13 bbls. cement, at \$1.33.....	17.30
12 cu. yds. fine gravel, at 88 cts.....	9.60
Total for 400 ft. of pipe.....	\$41.00

This is equivalent to $10\frac{1}{4}$ cts. per ft. In none of these cases is the cost of digging the trench included in the labor item, for that cost is common to all kinds of pipe sewers. However, due to the fact that there are no bells on the cement pipe and no joints to be made, the trench can be dug about 6 ins. narrower than where vitrified pipe is used, thus effecting considerable saving in the cost of excavation.

It was noted that in building the 8-in. pipe the men in the trench were capable of putting in pipes at the rate of 1 lin. ft. per minute, which was just about twice what they averaged for the whole job.

The speed depends very largely upon the man who is packing the mortar into the mold, and as this is hard work, it would be advisable to let him change places frequently with the man who works the lever that pulls the mold ahead. By having two strong and willing men in these positions, it is believed that 500 lin. ft. of 8-in. pipe could be built in 10 hours, day in and day out.

The molds for making this pipe are made by the Ransome International Conduit Co., 11 Broadway, New York City.

Cost of Cleaning a Large Brick Sewer.—Mr. Frederick L. Ford gives the following, relating to work done in Hartford, Conn., in 1905.

The Franklin avenue sewer cleaned consists of 9,269 lin. ft. of circular brick sewer, 5,128 ft. of which is 6 ft. inside diameter; 2,225 ft. 4 ft., and 1,916 ft. 3 ft. inside diameter. This sewer was built in 1872-73, at a cost of about \$150,000, and drains a district containing about 1,167 acres. It has never been thoroughly cleaned since it was built. The sewers which discharge into this trunk sewer vary from 8 in. to 3 ft. in diameter, and have grades ranging from 0.5 to 6.0 ft. per hundred. The 6-ft. Franklin avenue sewer has a grade of 2 ft. per 1,000, and the 4 and 3-ft. sections a grade of 3 ft. per 1,000.

The first work done was a thorough inspection of the sewer to determine the location and amount of the deposits. In the 6-ft. sewer this was an easy task with lanterns, and the material was found only in patches on the bottom, averaging from 6 in. to a foot deep and from 50 to 150 ft. in length, located usually just below where some large tributary sewer entered the Franklin avenue sewer.

It was impossible to make a thorough advance inspection of either the 4 or 3-ft. sections of the sewer, as the manholes were, as originally built, sometimes 1,000 ft. apart, and the ventilation so bad that we found it suffocating and too dangerous to enter either for any great distance from any manhole.

The deposits in the 3-ft. sewer were found, upon opening the sewer, to average about 1 ft. in depth and the ordinary sewage, about 6 to 8 in., was running on top of it, so there was little available working space left.

The cleaning was done by a contractor on a percentage basis (15%). The laborers received \$2 a day, and their foreman received \$15 per week.

Before commencing the cleaning, manholes were built where necessary, so that they are now not more than 200 ft. apart, and often less on the smaller sizes.

In cleaning, the force was organized in small gangs, which could work to advantage; two starting at a manhole and working in opposite directions until they met the men coming in the opposite direction.

In the 6 and 4-ft. sections, wheelbarrows were used to convey the material to the nearest manhole, where it was hauled up and re-

moved in carts, each holding 1 cu. yd. In the 3-ft. sewer the men used palls to remove the deposit.

The result of the work was as follows:

Diam. sewer.	Length.	Loads.	Cost.
6-ft.	5,128 ft.	107	\$ 387.55
4 ft.	2,225 ft.	61	243.80
3-ft.	1,916 ft.	107	466.38
Total	9,269 ft.	275	\$1,097.73

The average cost per load (cubic yard) on 9,269 ft. of sewer was \$3.99, and the average cost per lineal foot was \$0.118.

Size of sewer, ft.	6	4	3
Cost per load.....	\$3.82	\$3.99	\$4.36
Cost per foot.....	0.075	0.109	0.243

The 6-ft. sewer was cleaned in 7 days. The total time on this work, including foreman and team, was 1,592 hours. This is equivalent to 22.7 men working 10 hours a day for 7 days.

The 4-ft. sewer was cleaned in 4 days. The total time was 1,900 hours, equal to 25 men employed 10 hours a day for 4 days.

The 3-ft. sewer was cleaned in 13 days. The time occupied was 2,019 hours, or an average of 15.3 men, working 10 hours a day for 13 days.

The average distance cleaned by each man per day on the 6-ft. sewer was 22 ft.; on the 4-ft. sewer, 33 ft., and on the 3-ft. sewer, 9 ft.

The total cost of the work, including manholes built, was \$1,395.47, of which 15% was paid to Mr. Charles H. Slocomb, who furnished the labor and materials and superintended the work.

Cost of Cleaning Sewers and Catchbasins.—The following tabulation shows the amount expended per mile per year for the past 21 years by the Bureau of Sewers of Chicago, Ill., in cleaning sewers and catch basins:

	Miles of sewer to maintain.	Cost of cleaning.	Cost per mile per year.
1887	474	\$ 50,264.65	\$106.04
1888	492	62,423.41	126.85
1889	712	61,503.01	86.38
1890	785	107,878.34	137.42
1891	888	123,620.44	139.21
1892	992	142,720.62	143.87
1893	1,145	132,633.51	116.64
1894	1,211	154,225.45	127.35
1895	1,248	134,424.44	107.71
1896	1,306	96,901.65	74.20
1897	1,345	91,414.89	67.96
1898	1,388	92,961.88	66.98
1899	1,424	72,439.07	50.92
1900	1,453	80,985.64	55.73
1901	1,475	94,369.87	63.98
1902	1,501	99,872.58	66.20
1903	1,529	118,303.41	77.27
1904	1,583	124,260.26	78.50
1905	1,615	127,003.97	78.64
1906	1,623	150,942.10	92.43
1907	1,673	204,329.37	122.13

The work is done by regular employes of the Bureau of Sewers, common laborers during 1907 receiving \$2.50 and up per 8-hr. day.

Cost of Cleaning Sewers and Catchbasins.—The following table shows the cost of sewers cleaned in the city of Chicago during the year 1907:

Method.	Feet cleaned.	Total.	Per ft., cts.
Flushing	2,485,900	\$29,060	1.17
Iron scraper	488,700	32,161	6.58
Wood scraper	6,200	204	3.29

A total of 24,974 catchbasins were cleaned at a cost of \$96,522, the average cost per basin being \$3.86. The work is done by day labor by the Bureau of Sewers, common labor being paid \$2.50 per day of 8 hours.

Cost of Sewage Purification at Providence, R. I.—The cost of treatment per million gallons of sewage during 1906 at Providence, R. I., was as follows: Chemical precipitation, \$3.50; sludge disposal, \$3.10. The population served by sewers in 1906 was about 182,000, according to the annual report of Otis F. Clapp, City Engineer. The sewerage system included 205.89 miles of combined sewers and 9.94 miles of storm sewers. The sewage was composed of manufacturing, wool washings, jewelers' dyeing and bleaching wastes, with domestic sewage, and the strength of average sewage (parts per 100,000) was: Albuminoid ammonia, total 0.729; soluble, 0.370; suspended, 0.359; chlorine, 45.58. Other data from Mr. Clapp's report were as follows: Daily flow of sewage in million gallons: Maximum, Dec. 31, 42.5; minimum, Aug. 19, 10.2; average for the year, 20.36. Average daily flow of sewage treated: 19,550,000 gals. Pounds of lime used per million gallons of sewage (treated): 637.75. Other chemical used: Copperas, 72.1 lbs. per million gallons. Cubic contents of settling basin up to water surface, when in use, in million gallons: 11.13. Per cent organic matter removed from sewage in terms of albuminoid ammonia. Total, 43.35; suspended, 85.07. Disposition of effluent: Discharged into Providence River off the end of Field's Point under 26 ft. of water. Volume of sludge produced in gallons per million gallons of sewage treated: 4,444.4. Per cent of solids in wet sludge: 7.43. Method of sludge disposal: Pressed and cake hauled by steam train to dump. Sludge pressing: Average number of gallons pumped per day, 86,893. Per cent of solids in wet sludge: 7.43. Pounds of lime added per thousand gallons of sludge: 23.97.

Sludge Disposal.—Description of machinery used: Sludge pumped by Shone ejectors (two, 500 gals.) to storage reservoirs; thence by gravity to forcing receivers (four, 8 ft. dia. x 12 ft. long); thence forced under 60 to 80 lbs. pressure per square inch up into the presses. The ejectors and forcing receivers are run by air pressure generated by one 150 and one 50-hp. air compressors actuated by electric motors; 18 filter presses are used, each with from 42 to 54 plates, with 8-in. center holes, forming cakes 36 ins. square and from 1½ in. to ¾ in. thick, between filter cloths which sur-

round the plates. Hours of operation of presses daily: 6.83. For light, heat and power, \$7.69 per day. Tons of sludge cake produced daily: 97.16. Per cent of solids in pressed cake: 27.7. Tons of solids in sludge cake produced daily: 26.97. Cost of operation per ton of solids: \$2.24. The quantities per day in above table are calculated on basis of 365 days' work.

Cost of Sewage Disposal, 6 Cities.—In *Engineering-Contracting*, Oct. 6, 1907, appeared a five-page article compiled from a report prepared by Mr. A. C. Gregory. It contains many valuable data relating to six cities, of which the following is a very brief abstract.

Chemical Precipitation, Providence, R. I.—Providence has the distinction of being the one large city in this country which treats all (except in time of heavy storm) of its sewage by chemical precipitation, the object, of course, being clarification. This is all that is considered necessary, inasmuch as the clarified effluent is discharged into the Providence River and speedily carried into Long Island Sound, where the dilution is amply sufficient to take care of what organic matter remains in the effluent.

The disposal works consist of a pumping plant, chemical house, precipitation tanks and sludge compressing house with sludge well and tanks and a chemical laboratory.

A pound of lime used as a precipitant produces 10 lbs. of sludge (Dunbar, 1908) and that the amount of sludge amounts to about three times that produced by sedimentation or septic tank action.

Population in 1907, 208,000.

Population served by sewers, about 185,000.

Length of sewerage system: Combined, 209.8 miles; storm, 10.11 miles.

Character of sewage: Manufacturing, wool washings, jewelers, dyeing and bleaching waste, with domestic sewage.

Daily flow of sewage, in gallons: Maximum, 40,462,000; minimum, 9,424,000; average for year, 19,329,000.

Pounds of lime used per million gallons of sewage treated, 652.54.

Other chemicals used: Copperas, 82.05 pounds per million gallons.

Volume of sludge produced in gallons per million gallons of sewage treated, 4,504.

Per cent of solids in wet sludge, 7.85.

Average number of gallons of sludge pumped per day, 52,569.

Hours of operation of sludge presses per day, 671.

Tons of sludge cake produced daily, 96.84.

Tons of solids in sludge cake produced daily, 28.2.

Cost of treatment per million gallons of sewage: Chemical precipitation, \$2.54; sludge disposal, \$2.07; total, \$4.61 per million gallons.

Annual cost of maintenance about 22.4 cts. per capita.

Per cent of organic matter removed from sewage in terms of albuminoid ammonia, 44.74, and of suspended matter, 83.92.

In the analysis of sewage the amount of albuminoid ammonia found is a valuable index of the amount of organic matter present.

Chemical Precipitation, Worcester, Mass.—The Worcester disposal plant consists of a chemical house for storing and mixing the lime precipitant, and also containing sludge presses, a chemical laboratory, 16 precipitation tanks and 61 acres of filter beds.

The sludge is finally deposited at a distance of about a mile from the works. During the year ending with Nov. 30, 1908, 15,980,000 gals. of semi-liquid sludge were pumped from the precipitation tanks. After as much as possible of the liquid had been drawn off the remaining 12,074,000 gals. were pressed into sludge cake, amounting to 12,987 tons. Of this about 10,000 cu. yds. were taken as fertilizer by farmers.

The above figures, together with those that follow, are taken from or based upon the report of the city engineer for 1908:

Average daily quantity of sewage treated (precipitation), 11,240,000 gals.

Length of time sewage remains in tanks, 4 to 8 hours.

Volume of sludge per million gallons of sewage, 3,872 gals.

Cost of tanks, \$265,628.75.

Cost of maintenance for year, including disposal of sludge, \$35,671.15.

Kind and quantity of chemicals used per 1,000,000 gals., 871 lbs. of lime.

Cost of chemical precipitation per 1,000,000 gals., \$4.82; sludge pressing, \$3.85; total, \$8.67.

Annual cost of maintenance per capita, about 26.5 cts.

In terms of albuminoid ammonia chemical precipitation removes 87.3% of the total organic matter and 75.3% of the suspended organic matter.

Intermittent Sand Filtration, Worcester.—There are in use about 61 acres of sand filters, divided generally in units of one acre and having a depth of from 4 to 6 ft. A large part of this area is a natural sand bed, by reason of which fact a considerable saving was effected. At the bottom of the beds are laid parallel lines of drain pipes at intervals of about 50 ft. These collect the effluent and carry it to an intercepting pipe, whereby it is conveyed to the main effluent channel and finally reaches the Blackstone River.

Date of construction of works, 1899-1908.

Cost of beds, \$263,340.93.

Total filtering area, 61 acres.

Average area of beds, 0.98 acre.

Average daily quantity of sewage treated, 4,022,000 gals.

Average daily quantity treated per acre, 79,000 gals.

Annual cost of maintenance per capita, about 10½ cts.

Sewage flows on one bed, two to six hours.

Beds used, one to four times weekly.

Cubic yards material removed from surface of beds, 22,804.

Cost of removing same, \$8,580.

Total cost of maintenance for year, \$13,555.27.

Cost of maintenance per million gallons of sewage treated, \$9.31.

The net cost of maintenance per capita for both sand filtration and chemical precipitation is slightly less than 27 cts.

Intermittent Sand Filtration, Brockton, Mass.—There are 27 filter beds of an acre each. The use of water meters has brought water consumption down to 35 gals. per capita.

The sewage runs by gravity to a sump (pit) passing through screens before entering the sump, and from which it is pumped to the disposal beds about three and one-quarter miles away. About 110 lbs. of refuse per 1,000,000 gals. is screened out before the pumping. No pumping is done at night, the sewage being allowed to collect during that time, and is pumped away on the following day. A considerable amount of sediment is deposited in the sump. This is stirred up, pumped to the disposal plant, and applied to beds, of which there are five, especially used for that purpose, an average of about 136,000 gals. of sludge sewage being thus treated each day. The average amount of sewage treated per day at Brockton amounts to about 1,208,000 gals. The minimum seems to be about 1,072,000 gals., and the maximum about 1,433,000 gals. This would indicate a rate of about 45,000 gals. per acre per day.

The population of Brockton is estimated at 55,000.

The above figures are for 1908. In reaching the bed from the pumping station the sewage travels 3.3 miles and is raised 42 ft.

The Brockton plant has been placed in a spot naturally lending itself to economical construction. For the most part the preparation of the beds consisted in removing the upper soil so as to leave exposed the sand and gravel underneath. Under drains were put in only where the sand at a depth of 5 or 6 ft. was too fine to allow the sewage to percolate freely through it. Where such a condition existed drains with open joints were placed about 40 ft. apart. Banks were also raised and the necessary dosing arrangements made.

The disposal plant, up to Jan. 1, 1909, has cost \$227,483.64.

Seven new beds, constructed in 1907 and 1908, were completed at a cost of \$23,239.06, or at about \$3,320 per bed.

The expense for maintenance of the beds during 1908 amounted to \$6,169.04, or about \$12.63 per million gallons filtered, or 11.3 cts. per capita.

Intermittent Sand Filtration, Saratoga, N. Y.—Saratoga has a population of 12,000 to 60,000, according to the season of the year.

The filter beds handle 100,000 gals. per acre per day. The plant cost \$200,000, including \$65,000 for metering water supply and for

drains designed to separate the storm water. Some of the items of cost were:

Pumping plant.....	\$11,000
Force main.....	24,500
Septic tanks.....	15,500
Filter beds.....	48,000
Total	\$99,000

The operation of the pumps costs \$700 per year.

The cost of maintenance of beds for 1907, according to figures secured on the ground, was \$1,833.47, and for 1908, \$1,153.07.

Mr. Barbour states that the total cost of maintenance per year amounts to about \$3,000. Assuming the normal population at 12,000, a rate of 25 cts. per capita per year is indicated.

Septic Tanks and Contact Beds, Ballston Spa, N. Y.—Ballston Spa has a population of about 6,000, although being somewhat of a summer resort, the population varies. The plant was designed to deal with an estimated flow of 1,000,000 gals. per twenty-four hours.

No figures are in our possession as to expense of maintenance. The management, at the time of our visit, appeared to be in the hands of one man, who not only looked after the electrically driven pumps but the disposal works as well. Probably one man is all that is necessary for such a plant except in extraordinary occasions. The following is the cost of the plant as it appears in the accepted bid:

Septic tanks, beds, etc.....	\$39,456
Receiving tanks, pumping outfit.....	15,254
Pump house.....	3,072
Two gate houses.....	1,118
Force main (\$1.68 per foot).....	4,536
Sewer extension (\$1.41 per foot).....	1,551
Crushed stone (\$0.90 per cubic yard).....	18,000
Total	\$82,987

Estimated Cost of Sewage Filtering.—Profs. C. E. A. Winslow and E. B. Phelps read a paper before the Boston Society of Civil Engineers, in 1907, wherein the following estimates were given of the probable cost of a 50-acre trickling or percolating sewage filter were given. It was estimated that 2,000,000 gals. per acre would percolate daily through a bed of broken stone 8 ft. thick. It was estimated that such filter could be built for \$1,800,000, or \$36,000 per acre, including all necessary land (Thompson's Island), grading, etc. The cost of treating the sewage was estimated thus per million gallons:

Capital charges.....	\$3.50
Operation, including extra pumping.....	2.00
Chloride of lime.....	1.50
Total	\$7.00

It is not stated what the land was estimated to cost.

Cost of Sewage Filters, Pawtucket, R. I.—Mr. George A. Carpenter gives the following relative to a sewage filter at Pawtucket, R. I.

The filter serves 7 miles of sewers, combined system, draining 960 acres, with a population of 9,500. These 7 miles of sewers deliver 58,000 gala. per day, as the average for the year (1895), more than half of this being ground water which enters the sewers, notwithstanding underdrains beneath of some sections of the sewers. There are 13 filter beds having a total filtering area of 2.36 acres; four of these beds (0.51 acres) being sludge beds, and receive the sewage from the bottom foot of the settling tanks. The two settling tanks are each 30 x 100 ft., 4 ft. deep. Sewage is held 24 hrs. in these tanks, and then delivered through 8-in. pipes to the filter beds in doses of 100,000 gala. to the acre. The underdrains are 4-in. tiles, buried 5 ft. deep in the natural sand that forms the filter beds. The cost of this plant was \$12,000, or about \$5,000 per acre of filter bed. One man operates the plant.

Cost of Sewage Filters, Waterloo, Ont.—Mr. Herbert J. Bowman gives the following relative to the cost of sewage filter beds built in 1895 for Waterloo, Ontario. The work was done by contract. Six filter beds were built, each averaging 132 x 200 ft., or 26,400 sq. ft., or a total of 3.65 acres, with an available filtering area of 3 acres. The land is of sand and gravel, requiring little levelling up. The beds are underdrained by 3-in. tiles, laid 10 ft. apart in a tile gutter composed of 5-in. half-tile, with joint covers of quarter-tile. The contract cost of 10,545 ft. of 3-in. tile in place (for 4 of the beds) was as follows:

Materials, 10,545 ft. at 2.5 cts.....	\$ 264
Laying 10,545 ft. at 3.5 cts.....	369
1,856 cu. yds. gravel backfill at 20 cts.....	371
Removing surplus earth.....	129

Total, 10,545 ft. at 10.75 cts.....\$1,132

The trenches were dug 4 ft. deep, and backfilled with gravel which cost 20 cts. per cu. yd. delivered. The 3.5 cts. per lin. ft. for "laying" included digging the trench and backfilling, at which price the contractor barely paid his men, and had no profit.

The entire cost of the 6 beds, with 3 acres of filtering area, was:

2,050 cu. yds. excavation for embankments at 12 cts.....	\$ 266
1,500 cu. yds. gravel for levelling up beds at 20 cts.....	300
15,800 lin. ft. 3-in. drain at 10% cts.....	1,699
Sewer carriers (18-in.).....	300

Total\$2,565

This is equivalent to only \$900 per acre. The low cost is due to favorable conditions and to very low contract prices. The excavation for embankments was done with drag scrapers. The 3.6 acres of land cost \$100 an acre in addition to the above cost.

Cost of a Sewage Filter and Septic Tank With Costs of Operation.—Mr. F. A. Barbour gives the following relative to a sewage filter and septic tank plant at Saratoga Springs, N. Y., built in 1902.

**Engineering-Contracting*, July 14, 1909.

The sewage is lifted 15 ft. by three electrically driven centrifugal pumps (6-in.), and carried 8,800 ft. through a 16-in. cast-iron main, and then passed in succession through covered septic tanks, an aerator, an automatic dosing tank and intermittent sand filters. The volume ranges from 1,250,000 gals. to 2,500,000 gals. per day, the latter during the summer. The regular population is about 12,500, which increases to 50,000 during the summer.

The pumps and motors have an average combined efficiency of 35%. They cost \$5,400. The pump, well and building cost \$4,000. The pumps work only during the day. The 4 septic tanks are of concrete with a concrete vaulted roof, each being 52 x 91 ft. in area. The total capacity of the 4 tanks is 1,000,000 gals., the sewage being 3 ft. deep.

The aerator and dosing tank hold 26,000 gals.

There are 20 filter beds of about 1 acre each. About 2½ to 3 ft. of topsoil was excavated (and built into embankments) exposing the natural sand bed.

The cost of the plant was as follows (exclusive of a \$40,000 storm water built to reduce the amount of sewage treated):

Pumping plant and accessories.....	\$11,000
Force main (16-in.) 8,800 ft.....	25,000
Septic tanks, 1,000,000 gals.....	15,000
Filter beds, 20 acres.....	48,000
Total	\$99,000

The cost of pumping and operating the purification works is \$3,000 a year, of which \$720 is for the electric power, and \$600 covers all services at the screen and pumps. At the filter beds, \$1,680 a year is spent, of which 66% is for work not relating to the maintenance of the surface of the filter bed, being trimming embankments, weeding drives, etc.

In midsummer 12 filter beds are used daily, the gates being changed twice; during the remainder of the year 8 beds are used daily, the gates being shifted once. The average daily amount of sewage per bed in use is about 140,000 gals., applied in four doses. All the filter beds are kept in commission and the beds are used alternately, so that the average daily rate for the field is 60,000 gals. per acre. Mr. Barbour believes that double this rate could be maintained with equally good results.

Assuming a cost of \$3,000 per year for operation and \$5,000 per year (5% of \$100,000) for capital charges, we have a total of \$8,000 per year, to which may be added, say, \$1,000 for repairs and depreciation of pumping plant, making a grand total of \$9,000, or less than \$30 a day for treating 1,200,000 gals., or about \$25 per million gals.

Cost of Cleaning Sewers and Catch Basins.*—Mr. Allen Aldrich gives the following relative to the cost of cleaning 173 miles of

*Engineering-Contracting, Aug. 11, 1909.

sewers at Providence, R. I., during 1898. There were in use 4,026 catch basins ($23\frac{1}{4}$ per mile), each of which was cleaned, on an average, $3\frac{1}{2}$ times during the year. The 14,522 cleanings yielded 10,600 cu. yds. of deposit, or about 0.7 cu. yd. per cleaning. A gang of 2 laborers and 2 one-horse carts with drivers averaged 20 cu. yds. per day, cleaned out and hauled away. Assuming men's wages to be \$2 each and a horse to be \$1, the daily wage of this gang would be \$10, and the cost would be 50 cts. per cu. yd. of sludge, or 35 cts. per catch basin per cleaning. The labor cost for the year would then be about \$300 per mile of sewer, since 600 cu. yds. were removed per mile.

In addition to this, about 10.4 miles of sewers were flushed out with a fire hose during the year, yielding 831 cu. yds. more.

In cleaning the catch basins a man descends into the basin and first bails out the water into the sewer, until nothing but sludge is left; and the sludge is removed with buckets raised by a "wheel derrick" (a tripod with a drum operated by the wheels on which the derrick is transported) and dumped into the cart. Steel carts holding 1 cu. yd. are used.

Mr. T. Chalkley Hatton describes a more economic method of cleaning catch basins, which involves a special design of catch basin, so that the sludge accumulates in a "catch bucket." This galvanized catch bucket is 3 ft. high and $2\frac{1}{2}$ ft. diam. at the top. A cast-iron hood is placed over the outlet to the sewer, for trapping the sewer gases. This hood is removed before raising the catch bucket. Riveted to the top of the bucket is an angle iron that rests on a ledge in the catch basin, the joint being merely dirt proof and not water proof. The bucket is raised with a "wheel derrick" (a trip on wheels), by means of a friction pulley. The legs of the derrick are of gas pipe.

A brick catch basin (8 ft. 8 ins. deep) on a 6-in. concrete foundation, with a bucket, hood, and connections complete, costs \$40. Each connecting inlet costs about \$35. The "wheel derrick" costs \$35. Two men, with a horse and cart, can clean 20 catch basins a day, at a cost of 25 cts. per catch basin.

Cost of Flushing Sewers.*—Mr. Andrew Rosewater gives the following relative to the cost of flushing sewers by automatic flush tanks and by hand. The costs are estimated, but said to be based upon actual performance.

In 1893 Mr. Rosewater designed flush tanks that averaged 400 gals. capacity each and discharged at the rate of 11 gals. per second, developing effective scour in an 8-in. sewer for a distance of 2,000 ft. below the tank. To avoid sedimentation in the pipe that serves the flush tank, Mr. Rosewater states that the velocity of flow should not be less than 2 ft. per sec., and this is attained in a $\frac{1}{2}$ -in. pipe discharging 445 gals. in 24 hrs. A larger pipe causes decreased velocity and sedimentation where unfiltered water

**Engineering-Contracting*, July 28, 1899.

is used. He estimates the cost of maintenance and operation of each flush tank as follows per annum, provided the flush tank is properly designed:

Interest on \$100 tank at 5 per cent.....	\$ 5.00
Water, 182,000 gals. at \$15 per million.....	2.73
Labor of attendance (\$2,000 ÷ 300 tanks).....	6.67
Total per tank per year.....	\$14.40

Two men with a horse and wagon (costing \$2,000 per year) are estimated to be able to take care of 300 flush tanks and maintain them in repair.

In 100 miles of sewers in Omaha, Mr. Rosewater found that the existing flush tanks were using 1,800,000 gals. daily, which was three times the amount needed if the flow had been properly adjusted.

If flushing is done by hand labor, there are three methods available: (1) Water carts; (2) direct portable base connections to hydrants; and (3) connection with pipe mains and hand valves.

Flushing with water carts requires two men, at \$1.50 each, and two horses, at \$0.75 each, to handle 25 tanks per day, or 18 cts. per tank per day, or \$65.70 per tank per year, to which must be added \$2.73 for the water, making a total of \$68.43.

Flushing with portable base requires 2 men and a horse, who handle 30 tanks daily, at a cost of \$49.25 per year per tank, to which must be added \$2.73 for water, making a total of \$49.25.

Flushing with pipe connection and hand valves requires the construction of a manhole, which, with connections, etc., will cost \$100. One man with a horse and wagon can handle 40 tanks daily, at a cost of \$22.50 per tank per year. To this must be added \$5 for interest and \$2.73 for water, making a total of \$30.25.

Cost of Vitrified Conduits and of Tile Drains, Cross-References.—Data on these subjects will be found in Section XV, Miscellaneous Cost Data.

SECTION IX.

PILING, TRESTLING AND TIMBERWORK.

Definitions.—Consult the index for words not found in the following alphabetical list

Adz.—A carpenter's chipping tool, like a small hoe with a handle.

Angle Block.—A block of cast iron or wood, having a triangular cross-section, against which the braces and counters of a Howe bridge truss abut.

Apron.—A covering at the foot of a spillway, to protect the ground from scour.

Balk.—A large stick of timber.

Batter Piles.—Piles driven inclined, as distinguished from plumb piles.

Bent.—One of the transverse frames of a trestle which supports the "deck" or floor system. It consists of a sill, a cap, posts (vertical and batter), and sway braces. A pile bent consists of the piles, cap and sway braces.

Bit.—The part of an auger that does the boring.

Block and Tackle.—A pulley block and rope.

Board Measure.—The unit of timber measure is the board foot (ft. B. M.), which is 1 ft. square and 1 in. thick, or 1/12 cu. ft. A thousand feet board measure (1,000 ft. B. M.) is often designated by the letter M.

Box Culvert.—A culvert having a water way of rectangular cross-section.

Brace.—A diagonal compression member of a truss, also any stick used to resist compression, like the horizontal timbers running from one side of a trench to another. Sway braces are the diagonal braces of a trestle bent. Lateral (or wind) braces are the diagonal braces between the lower, or the upper, chords of a Howe truss bridge.

The frame that holds a bit or auger is called a brace.

Brad Spike.—A railway spike.

Brash.—Brittle.

Bridging.—The small diagonal braces between two joists or stringers of a floor system, which prevent the joists from turning over on their sides, or from buckling laterally.

Brush Hook.—A curved blade, mounted on a wooden handle, used for cutting brush.

Burnettizing.—Impregnating the pores of wood with a solution of zinc chloride under pressure.

Burr.—The nut of a bolt.

Calk.—To fill joints with oakum, or the like, to prevent leakage.

Cast.—To tip or lean.

Cast Hook.—A tool for handling timber. It is like a peavey, except that the pole or handle is not pointed.

Cap.—A timber across the tops of posts or piles, and usually driftbolted thereto.

Centers.—The falsework that supports an arch during construction, or, more strictly, the arch ribs of this falsework.

Check.—A crack in timber due to shrinkage from seasoning.

Clear Inspection.—A class of timber conforming to some such specification as follows (N. Y. Lumber Assoc.):

"Scantling and plank shall be free of sap, large knots or other defects. Dimension sizes shall be free from sap, large or unsound knots, shakes through or round."

Clearing.—The removal of all trees and brush above the ground level. The removal of the roots below the ground level is grubbing.

Close Piles.—Sheet piles.

Corbel.—A projecting beam acting as a cantilever supporting another beam.

Cord.—A cord of wood measures 4 x 4 x 8 ft., or 128 cu. ft.

Corduroy.—A road made of round or split logs laid side by side upon marshy ground.

Creosoting.—Impregnating the pores of timber with hot creosote (dead oil of coal tar) under pressure.

Crib.—A log cabin structure built of timbers whose ends are notched and drift bolted together.

Dap.—A notch cut into the side of a stick of timber.

Deck.—The wooden floor system of a railway bridge, consisting of the stringers, cross-ties and guard rails.

Deciduous.—Subject to shedding leaves in the fall and winter, as distinguished from evergreen.

Docking.—A retaining wall of piles sheathed with plank, and capped with a "dock stick" bolted thereto.

Dolly.—A roller upon which is mounted a small truck for carrying timber.

Dimension lumber.—Sticks measuring 6x6 in. and larger.

Dosey.—Sap rotted.

Dovetail.—A timber joint made by cutting the end of a stick so that it is narrower a few inches back of the end, and is let into a cross timber notched to fit it.

Dowel.—A short iron pin inserted into bored holes in two faces of sticks that meet. Usually a dowel is used to hold the foot of a trestle post from displacement from the sill on which it rests.

Dressed.—Planed.

Drift bolt.—A bar of round iron ($\frac{3}{4}$ to 1 in.) used like a large nail (without a head) to fasten timbers together. An auger hole, $\frac{1}{16}$ to $\frac{1}{4}$ in. smaller than the drift bolt, is first bored and the bolt is driven in the hole.

Drop Timbers.—Timbers dropped into place to close an opening in a dam.

Dry rot.—Rotting of timber not exposed to rain. The moisture is supplied by the sap of the timber. Dry rot often occurs when green timber is painted, the paint preventing the evaporation of the sap.

Dubb.—To cut the end of a stick to a bevel around the edge. It is usually good practice to dubb the end of a pile preparatory to ringing it.

Falsework.—The temporary frame work or staging built to support a bridge or other structure during its erection.

Fascine.—A bundle of brush or small branches wired or tied together.

Flume.—A trough for carrying water.

Follower.—A short length of pile placed on top of the pile that is being driven, to protect it from the blows of the hammer, or to force it down below the bottom of the leaders as when driving under water.

Forms.—The mold in which concrete is cast.

Frame.—To shape the members of a timber structure. Sometimes the term is used to include the erection and fastening together of the members.

Frap.—To bind together with a rope.

Gib or Gib Plate.—A large flat plate of wrought iron or steel, used like a washer between the timber and the nut heads of rods in a Howe truss.

Gin or Gin Pole.—A mast with a pulley at the top, guyed with three or four ropes, and used to raise heavy timbers, etc.

Gins.—See Leads.

Grillage.—Timbers laid criss cross, bolted together and fastened by drift bolts to the heads of foundation piles.

Grub.—To remove the roots of trees and brush.

Jetting Piles.—To sink piles by means of a water jet.

Joist.—A beam or stringer that supports flooring.

Kerf.—The narrow slot made in sawing timber.

Kiln Dried.—Dried artificially in a kiln.

Knot.—The American Society for Testing Materials adopted (1906) the following definitions: (1) A *sound knot* is one which is solid across its face and which is as hard as the wood surrounding it; it may be either red or black, and is so fixed by growth or position that it will retain its place in the piece. (2) A *loose knot* is one not firmly held in place by growth or position. (3) A *pith knot* is a sound knot with a pith hole not more than $\frac{1}{4}$ in. in diameter in the center. (4) An *encased knot* is one which is surrounded wholly or in part by bark or pitch. Where the encasement is less than $\frac{1}{2}$ of an inch in width on both sides, not exceeding one-half the circumference of the knot, it shall be considered a sound knot. (5) A *rotten knot* is one not as hard as the wood it is in. (6) A *pin knot* is a sound knot not over $\frac{1}{2}$ in. in diameter. (7) A *standard knot* is a sound knot not over $1\frac{1}{2}$ in. in diameter.

(8) A *large knot* is a sound knot, more than $1\frac{1}{2}$ in. in diameter. (9) A *round knot* is one which is oval or circular in form. (10) A *spike knot* is one sawn in a lengthwise direction; the mean or average diameter shall be considered in measuring these knots.

Lagging.—The plank sheeting placed upon the frames of arch centers.

Lag Screw.—A thick screw with a square bolt head.

Leads or Leaders.—The vertical guides that guide a pile driver hammer during its rise and fall. Also called gins, ways, etc.

Lug Hook.—A timber grapple, much like ice tongs hung from the center of a wooden handle; used for carrying timber, one man at each end of the handle.

Mattock.—A grubbing tool with one cutting edge shaped like an adz (or hoe), and the other edge like an ax or pick.

Mattress.—A brush mattress consists either of fascines bound together, or of strands of brush woven together, ballasted with stone and sunk in a river bed to prevent scour.

Merchantable Timber.—According to specifications of the Southern Lumber and Timber Assn.: "Scantling shall show three corners heart free from injurious shakes or unsound knots. Plank nine inches and under wide, shall show one heart free and two-thirds heart on opposite side; over nine inches wide shall show two-thirds heart on both sides, all free from round or through shakes, large or unsound knots. Dimension sizes: All square lumber shall show two-thirds heart on two sides and not less than half heart on two other sides. Other sizes shall show two-thirds heart on faces and show heart two-thirds of the length on edges excepting where width exceeds thickness by three inches or over, and then it shall show heart on the edges for half its length. All stock to be well and truly manufactured full to size and saw butted."

Miter.—The joint between two beveled edges, the bevel usually being 45 degrees.

Mortise.—A hollow cut made in the side of a timber to receive the tenon or tongue on the end of another timber.

Mud Sills.—Short pieces of timber (often cedar) laid beneath the sill of a trestle bent to keep it from contact with the ground.

Needle Beam.—Floor beam of a Howe truss, through the ends of which pass the vertical rods.

Nippers.—The scissor-like tongs that clutch the hammer of a free-fall pile driver.

Overhang Driver.—See Pile Driver.

Packing Piece.—A piece of wood or metal placed between two timbers to prevent their coming in contact.

Peavey.—A pointed pole with a pivoted hook near the pointed end, used for handling timbers. See Cant Hook.

Pile.—A stick driven into the earth. *Foundation piles* are driven to support a bridge, building or other structure. *Sheet piles* are sawed timber piles driven touching one another, so as to form a tight diaphragm. *Wakefield piles* are sheet piles made by bolting

or spiking three planks together, so as to form a tongue and groove. When driven, this gives a triple lap sheet piling.

Pile Driver.—A free-fall pile driver has a hammer held by nippers which, when tripped, allow the hammer to fall freely. A friction clutch driver has its hammer always attached to the hoisting rope, which is operated by the drum with a friction clutch. A steam hammer is raised by steam acting directly upon a piston attached to the hammer. An overhang driver is one mounted in a frame whose leads project 8 to 20 ft. beyond the base of support.

Pinch Bar.—A steel bar with a chisel-shaped end.

Pitch Pocket.—The American Society for Testing Materials gives the following specification: *Pitch pockets* are openings between the grain or the wood containing more or less pitch or bark. These shall be classified as small, standard and large pitch pockets. (a) A small pitch pocket is one not over $\frac{1}{2}$ of an inch wide. (b) A standard pitch pocket is one not over $\frac{3}{4}$ of an inch wide, or 3 ins. in length. (c) A large pitch pocket is one over $\frac{3}{4}$ of an inch wide, or over 3 ins. in length. A *pitch break* is a well-defined accumulation of pitch at one point in the piece.

Plank.—In the lumber trade, the term plank is applied to pieces $1\frac{1}{2}$ to 6 ins. thick \times 7 ins. wide, or wider.

Posts.—The upright members in a trestle bent.

Put Logs.—Horizontal stringers supporting a building scaffolding, the ends being inserted in put-log holes left in the masonry.

Rangers.—The longitudinal timbers used in bracing a trench; the "braces" being the cross timbers between the rangers.

Revetment.—A river bank protection.

Ring.—An iron band around the head of a pile to protect it from splitting or brooming.

Scantling.—A timber of small cross-section. Also the cross-section dimensions, as a "scantling" of 4 \times 10 ins.

Scarf Joint.—A joint made by overlapping and bolting or locking together the ends of two pieces of timber that are halved, notched or cut away, so that they will fit each other and form a lengthened stick of the same size at the scarf joint as elsewhere.

Scissors.—See Nippers.

Seasoned.—Air dried.

Sheet Piles.—See Piles.

Shoe.—An iron point over the lower end of a wooden pile.

Sill.—The horizontal timber of a trestle bent on which the posts rest.

Sheeting or Sheathing.—Plank or boards forming a wall, or a diaphragm.

Skeleton Bracing.—Trench bracing consisting only of rangers and cross braces, without any plank sheeting.

Stay Lathed.—Temporarily fastened with small cleats or braces.

Stringer.—A longitudinal joist in a floor system.

Studs.—The vertical pieces of timber (in a building) to which sheeting is fastened.

Stumpage.—The amount paid a land owner for standing timber.

Tenon.—A projecting tongue cut on the end of a stick of timber.

See Mortise.

Tongs.—See Nippers.

Treated.—Preserved by impregnation with creosote, zinc chloride, or the like.

Trestle.—A bridge consisting of bents supporting a floor system. A *frame* trestle consists entirely of sawed timber. A *pole* trestle is made largely of round poles, none of which, however, are used as piles. A *pile* trestle has bents composed of piles. See Bent.

Wakefield.—See Pile.

Wale.—A longitudinal timber bolted to a row of piles; but not on top of the piles, such a timber being a cap.

Water Jet.—See Jetting.

Ways.—See Leads. Also the inclined timbers down which any structure is launched into the water.

Importance of Timberwork.—Although timber will be used to a less and less extent for permanent engineering structures, it will long have a wide field of usefulness for falsework, forms, centers, temporary trestles, etc. In foundations that are always under water, timber will doubtless never cease to be used to a considerable extent. In supporting the roofs of mining excavations timber may never cease to be used. Trestle bridges for railways are still built extensively in the West, and even in the East. In brief, there is and long will be an enormous amount of timber used annually in engineering construction. It is a serious mistake, therefore, to regard a knowledge of timberwork as being comparatively non-essential to the engineer of the future.

Measurement of Timberwork.—Timber is sold by the 1,000 ft. B. M. (thousand feet board measure). A common abbreviation for 1,000 ft. B. M. is the letter M. One foot board measure is 12 in. square and 1 in. thick, which is one-twelfth cubic foot. To estimate the number of feet board measure in a sawed stick, multiply the end dimensions (in inches) together and divide by twelve, then multiply this quotient by the length of the stick (in feet). For example, in a 10 x 12-in. stick, 16 ft. long, there are:

$$\frac{10 \times 12}{12} \times 16 = 160 \text{ ft. B. M.}$$

Timberwork is paid for at a specified price per M for the timber measured in the work. The contractor must be cautious to make allowance for wastage in framing the timber. Scarf joints, for example, may cause a wastage of 6%. If bridge flooring planks are laid diagonally for a 16-ft. roadway, there is a wastage of about 5% when the ends are sawed off on line with the outer stringers.

Timber is usually sold in lengths containing an even number of feet, as 10, 12, 14, 16 ft. In examining plans, the contractor should be careful to note whether the dimensions are such as to require the use of even lengths or not, for a careless engineer or architect may so design a structure as to cause a large wastage of timber.

In measuring dressed lumber, remember that the thickness used in calculating the number of board feet is not the actual thickness of the dressed board, but the thickness of the original stock from which the dressed board was made. So also the width of a tongue and grooved board is not its actual face width, as laid, but it is the width of the original board.

Cubic Contents and Weight of Piles and Poles.—Table I gives the cubic feet contents of a tapering pole. Thus a pole 8 in. diam. at the small end and 16 in. at the large end, contains 0.81 cu. ft. per lin. ft. of pole (see Table I). Hence if the pole is 30 ft. long, it contains $30 \times 0.81 = 24.3$ cu. ft. of timber.

The weight of timber per cubic foot is given below.

In estimating the amount of lumber that can be sawed from a log, the following rule is used:

From the least diameter in inches subtract 4, divide by 16, multiply by the length in feet, and the quotient is the number of feet board measure.

Expressed as a formula, we have

$$\text{Ft. B. M.} = \left(\frac{d-4}{16} \right) d L.$$

Weight of Timber.—The cost of hauling timber must frequently be estimated. Timber is bought by the M, and it is well to remember that an M contains $82\frac{1}{2}$ cu. ft., which at a specific gravity of 1 (the same as water) would be 5,200 lbs., or 2.6 tons per M. However, only very dense, green oaks, and similar dense timber, ever have a specific gravity equal to 1.

Table II gives the weight of timber for different specific gravities.

The following is the specific gravity of some of the common kinds of timber:

	Green.	Kiln Dried.
Yellow pine (Southern).....	0.90	0.60
Norway pine (Northern).....	0.50
Douglas fir	0.65
White pine	0.40
White oak	1.00	0.70
Hemlock	0.60	0.50
Cedar	0.35

See Frye's "Civil Engineer's Pocketbook" for the most complete data on weights of wood.

TABLE II.—WEIGHT OF TIMBER PER CU. FT. AND PER M FT. B. M.

Specific gravity.	Weight per cu. ft., lbs.	Weight per 1,000 ft. B. M., lbs.
1.0	62.40	5,200
0.9	56.16	4,680
0.8	49.92	4,160
0.7	43.68	3,640
0.6	37.44	3,120
0.5	31.20	2,600
0.4	24.96	2,080
0.3	18.72	1,560

Cost of Manufacturing Lumber.—A contractor will often find it profitable to cut and saw lumber. A 20-hp. portable engine will run a small sawmill, and with a crew of 5 men the output will be about 3,000 ft. B. M. of 3-in. plank per day. If the wages of the 5 men are \$10 a day, and the rental of the engine and saw is \$10 more per day, the cost of sawing is about \$2.50 per M. The price of the timber as it stands before cutting, is called the stumpage price, and this ranges from \$1 to \$5 per M. The cost of cutting and skidding hemlock logs, I have found to be about \$1 per M, half of which is for cutting and the other half for skidding, wages being \$1.50 a day. The total cost of sawed plank in one case was as follows:

	Per M.
Stumpage	\$1.50
Cutting	0.40
Skidding	0.60
Sawing	2.50
Total per M.....	\$5.00

I have been told by a lumberman in Washington that his "logging" cost him \$5 per M, wages of laborers being \$3 per day. This seems like a high cost. It includes cutting the trees and dragging the logs to an incline up which they are hauled by a hoisting engine to a chute, down which they are slid by gravity to tidewater.

Cost of Sawing and Planing Lumber.*—In connection with the operation and care of the Muscle Shoals Canal, U. S. Government Tennessee River Improvement, a small sawmill was used for sawing and planing lumber. This lumber was largely used in building and repairing boats and was usually sawed and planed just as needed. Consequently the mill was run very spasmodically, sometimes being in operation all day, and again only an hour or so. The men operating the mill were used on other work when not employed in the mill. The sawyer was paid \$50 per month and helpers from \$1.20 to \$1.50 per day of 8 hrs.

During the year 1904-5 a total of 77,591 ft. B. M. of lumber were sawed at an average cost of \$2.11 per M, and 56,121 ft. B. M. were planed at an average of \$1.38 per M.

The lumber ranged in size from 3 ft. to 45 ft. long and from 1-in. boards to sticks 20-in. x 20-in. in cross-section.

The planer, which would take a stick as large as 6 x 24 ins., was worked by the same operations as the sawmill.

The mill was run by a 55-hp. Victor turbine and had a 60-in. circular saw.

Price of Yellow Pine for Fourteen Years.†—The "American Lumberman," Aug. 22, 1908, gives a very complete table of prices of Southern yellow pine lumber of different classes, from which we have selected the prices of two classes only. These prices apply to lumber delivered at points that are reached by a 28-ct. rate (per

**Engineering-Contracting*, Aug. 29, 1906.

†*Engineering-Contracting*, Sept. 2, 1908.

160 lbs.) from the mills, and include the 23-ct. freight rate. The prices are as follows:

Year.	No. 1 Dimension 2" x 10" — 16'.	Timbers 4" x 10" to 12" x 12" — 16'.
1894	\$12.50	\$15.25
1895	12.25	15.25
1896	11.00	15.50
1897	12.50	16.00
1898	13.50	17.00
1899	13.50	17.75
1900	14.50	19.25
1901	15.50	20.00
1902	16.00	20.50
1903	16.00	20.50
1904	16.00	21.00
1905	17.50	22.25
1906	21.00	28.00
1907	22.25	28.25
1908	17.75	25.25

Life of Trestle and Bridge Timbers.*—A committee of the American Railway Bridge and Building Association reported in 1908 that the following is the average life:

	Years.
Caps of Trestles:	
Long leaf pine (av. of 12 yrs.)	10
Douglas fir (av. of 8 yrs.)	10
White or burr oak (av. of 2 yrs.)	11
Stringers:	
Long leaf pine (av. of 13 yrs.)	10
Douglas fir (av. of 10 yrs.)	11
White oak (av. of 1 yr.)	10
White pine with iron cover (1 yr.)	14
Ties:	
Long leaf pine (av. of 10 yrs.)	9
Douglas fir (av. of 4 yrs.)	12
White oak (av. of 4 yrs.)	10
Piles:	
White or burr oak (av. of 10 yrs.)	10
White cedar (av. of 6 yrs.)	17
Red cedar (av. of 2 yrs.)	12
Treated pine (av. of 2 yrs.)	14

In 1899 a committee of the same association made a similar report, of which the following is an abstract. It is not so reliable as the report above given.

The life of piles is as follows:

	Years.	
	In water.	On land.
Cedar, white (Wia.)	20+	20+
Cedar (Wia.)	28	16 to 20
Chestnut (New England)	15 to 20	12 to 18
Cypress (Ill.)	7	7
Oak (New Eng.)	9 to 20	8 to 14
Oak, white (Middle States)	8 to 20	8 to 12
Pine, yellow (Miss.)	10	10
Pine, Norway (Wia.)	7	6
Spruce (New Eng.)	4 to 10	4 to 8
Spruce, red (Colo.)	10 to 16	7 to 10
Tamarack (New Eng.)	18	10 to 12
Tamarack (Wia.)	8

*Engineering-Contracting, Nov. 25, 1908.

The life of unprotected bridge timber, whether in stringers, bents, or trusses, is as follows:

	Years.
Pine, yellow long leaf (New Eng.).....	12 to 20
Pine, yellow long leaf (Miss.).....	8
Pine, yellow long leaf (Ill.).....	8 to 14
Pine, yellow long leaf (Colo.).....	10
Pine, white (New Eng.).....	10 to 18
Pine, white (Ill.).....	10 to 14
Pine, white (Minn.).....	10
Pine, Colorado.....	8 to 15
Pine, Norway (Wis.).....	8 to 10
Spruce (New Eng.).....	5 to 10
Douglas fir (Wyo.).....	10 to 16
Douglas fir (Colo.).....	18 to 20
Oak, white (Ohio).....	7 to 8
Oak, white (Ill.).....	14 to 18
Cypress, red (Ala.).....	12

Even a casual study of these figures shows that many of them are merely rough guesses. For example, why should white oak timber in Illinois last twice as long as in Ohio. The reports for these two states are from different superintendents, which accounts for the discrepancy.

The life of timber truss bridges protected from the weather was reported to be 20 to 50 years, several superintendents saying indefinitely.

Consult the section on Railways for life of timber, particularly ties.

Life of Treated and Untreated Fence Posts.—A committee of the Am. Ry. Engrg. and Mn. of Way Assoc. reported in 1907 that the average life of fence posts is as follows:

Chestnut and oak.....	9 years
Locust.....	10 years
Catalpa.....	12 years
Cedar.....	15 years
Bois d'Arc.....	Everlasting

Mr. B. E. Buffum made some experiments in Wyoming with 30 pitch-pine fence posts, by treating them in three different ways. The posts were placed in 1891 and in 1907 the following conclusions were reached. The best treatment consisted in dipping the lower 2½ ft. of post in California (?) crude asphaltic oil and then burning off the outside oil. This drives the hot oil into the post and chars the outside. After 16 years these posts seemed good for a life of fully 30 years, as they were as sound as the day they were placed.

Of 15 untreated posts the life was estimated as follows:

Number.	Estimated life, years.
4	12
2	14
4	16
3	17
1	18
1	20+
15	Average. 15

A treatment of the lower 2½ ft. of the post with tar was less effective than with crude oil, and it seemed to make little difference whether the tar was burned off or not. Of ten posts thus treated 8 appeared to be good for a life of 20 years or more.

Posts simply well charred seemed good for a life of about 20 years.

For cost of fences see the sections on Railways and on Miscellaneous Costs.

Life of Creosoted Ties.—In 1880-2, some 150,000 ties were creosoted with 10 lbs. of oil per cu. ft. and put in the tracks of the Houston and Texas Central Ry. In 1907, there were still 11,200 in service, and Mr. O. Chanute estimated that the average life had been 19.35 years.

Cost of Treating Timber, Cross References.—The steadily advancing price of timber has lead to "treating" timber with preservatives, such as creosote and zinc chloride.

Cedar may be regarded as a timber containing a natural preservative—the oil of cedar, which is too often "killed" by kiln drying to reduce the weight before shipment.

In addition to the data in the following pages, consult that part of the section on Railways relating to tie preservation. See the index under "Timber, Preserving."

Process Treatment of Timber and Approximate Costs.*—Mr. G. B. Shipley is author of the following:

The evolution of timber preserving processes in this country within the last ten years has developed many new methods of treating ties, piling, timber, poles, crossarms, mine timbers, etc., and a great many antiseptics or compounds are being proposed, but the subject is of such vital importance that the leading organizations are backward about experimenting. Consequently the processes actually employed may be subdivided into only two methods and these are the full cell and partial cell treatments. The full cell treatment consists of impregnating the wood fibres and filling the cells with the antiseptic, whereas the partial cell treatment consists of impregnating the wood fibers only. These two methods are sometimes confused with processes or the manner in which the treatment is performed.

The treatment of wood depends upon where the wood will be used, the climatic conditions, the permissible cost of treatment and the wood structure. If first-class wood is to be used for such work as docks around salt water, telegraph poles, building foundations or for railroad ties, where there is no mechanical wear, the full cell method is best, but if the wood is soft and not protected from mechanical wear, then the partial cell method will be satisfactory for the reason that with the latter method the chemical life will be equivalent to the mechanical life.

*Engineering-Contracting, Jan. 19, 1910.

The important processes that are in use in this country and which may be classed under the full cell method are the burnettizing, Wellhouse, full cell creosote and card processes, and those which may be classed under partial cell method are the Reuping, Lowry and absorption processes. These processes, with the exception of the absorption process, are manipulated by mechanical contrivances, such as pressure pumps, vacuum pumps and air compressors and can be controlled to suit the wood structure, while with the absorption process the treatment is governed by temperature and atmospheric pressure, therefore is limited to certain woods.

Burnettizing Process.—This is often referred to as the zinc chloride process and consists of impregnating the wood fibers with a solution containing $\frac{1}{2}$ lb. of dry zinc chloride per cubic foot of wood and is operated as follows: The wood is first air seasoned in the open, or steamed in retorts to expel the moisture, then a vacuum is produced and maintained until the solution is introduced and the wood is completely submerged, the pressure is then increased to about 100 lbs. or 125 lbs. per sq. in., by pumping in additional solution until the required penetration and impregnation is obtained, when the solution is drained from the retort. The approximate time required for the process is:

	Hrs.	Mins.
Steaming to 20 lbs. pressure.....	0	30
Steaming, 20 lbs. to 35 lbs. pressure.....	3	30
Blowing off steam.....	0	15
Vacuum	0	45
Solution to about 100 lbs. pressure.....	0	45
Solution maintained to 100 lbs. pressure.....	1	15
Forcing back solution.....	0	15
Total cycle	7	15

If the steaming time is reduced 2 hrs., then the total cycle is 5 hrs. 15 mins.

Wellhouse Process.—This is often referred to as the zinc tannin process. It consists of impregnating the wood fibers with a hot solution containing about $\frac{1}{2}$ lb. of dry zinc chloride plus $\frac{1}{2}\%$ of glue or gelatine per cubic foot of wood, then following by injecting a second solution containing $\frac{1}{2}\%$ of tannic acid. The purpose of the tannin is to solidify the first injection to prevent leaching.

The wood is first air seasoned in the open or steamed in retorts to expel the moisture, then a vacuum is produced and maintained until the solution is introduced and the wood is completely submerged, the pressure is then increased to about 100 to 125 lbs. per sq. in. by pumping in additional solution until the required penetration and impregnation are obtained, when the solution is drained from the retort and the second movement takes place by filling the retort with a solution containing tannic acid and increasing the pressure by pumping in additional solution at about 100 or 125 lbs. per sq. in. until the required penetration is obtained, when the solution is drained from the retort. The approximate time required is:

	Maximum Hrs.	Time, Mins.
Steaming to 20 lbs. pressure.....	0	20
Steaming, 20 to 25 lbs. pressure.....	3	30
Blowing off steam.....	0	15
Vacuum	0	45
Solution and glue to 100 lbs. pressure.....	0	45
Solution and glue maintained at 100 lbs. pressure	1	15
Forcing back solution and glue.....	0	15
Tannin introduced to 100 lbs. pressure.....	0	20
Tannin maintained at 100 lbs. pressure.....	0	50
Forcing back tannin.....	0	15
Total cycle	3	40

If steaming time is reduced 2 hrs., then the total cycle equals 6 hrs. 40 mins.

Absorption Process.—This is often referred to as the non-pressure process consists of submerging the wood in a boiling preservative at a temperature of from 180° to 220° F., then following with a cold preservative as follows: The wood is first air seasoned in the open to reduce the moisture, then placed in either an open or closed receptacle where it is submerged in a hot preservative which expels the air and additional moisture; the receptacle is then drained and the wood submerged in a cold preservative. The first movement opens the pores or cells of the wood forming a vacuum within, while the second movement causes absorption due to the difference in temperature and atmospheric pressure. This process can be used in either open tanks or closed retorts. For treating the butts of poles, fence posts, piling and small quantities of ties the open tank is satisfactory, but for treating large quantities of material the closed retort is recommended where thorough impregnation is desired. The time of treatment is as follows:

Green Timber.

Boiling in hot preservative from 8 to 10 hrs.

Bath in cold preservative from 8 to 16 hrs.

Total time of treatment, 16 to 26 hrs.

Seasoned Timber.

Boiling in hot preservative from 3 to 6 hrs.

Bath of cold preservative from 4 to 8 hrs.

Total time of treatment, 7 to 14 hrs.

With this process it is possible to impregnate a limited class of woods with about 6 to 12 lbs. of concrete oil per cubic foot.

Full Cell Creosote Process.—This consists of impregnating the wood fibers and cells of ties with 6 to 12 lbs. of creosote oil per cubic foot and timber and piling with 10 lbs. to 20 lbs. of creosote oil per cubic foot, as follows: The wood is first seasoned in the open or steamed in the retorts (generally both) to reduce the moisture and expel the sap; then a vacuum is produced and maintained until the creosote oil is introduced and wood is completely submerged. The pressure is then increased to about 100 to 125 lbs. per sq. in. and maintained until the desired penetration and impregnation is secured, when the creosote oil is drained from the tanks. In some cases a vacuum is produced and maintained at the finish to drain the surplus oil from the exterior of wood to prevent loss by dripage

after the wood has been removed from retorts. The approximate time required is:

	10-lb. Treatment.	
	Hrs.	Mins.
Steaming to 20 lbs. pressure.....	0	30
Steaming, 20 to 35 lbs. pressure.....	2	30
Blowing off steam.....	0	15
Vacuum	0	45
Creosote to 100 lbs. pressure.....	1	30
Forcing back solution.....	0	15
Vacuum	30
Total cycle	7	15

If the steaming time is reduced 2 hrs., then the total cycle equals 5 hrs. 15 mins.

Equalizing Process.—This is often referred to as a partial cell treatment and it is used principally in connection with creosote oil. It consists of forcing compressed air into the pores or cells of wood and at a higher pressure creosote oil without relieving the air pressure and upon relieving the combined pressure the air expands and forces out the surplus oil, leaving wood fibres impregnated. The wood is first air seasoned in the open or steamed in the retorts (sometimes both) to reduce the moisture; with compressed air and by air equalizing reservoirs or pumps the retorts are filled with oil without releasing the air pressure. The oil pressure is thus started at from 80 to 100 lbs. per sq. in. and gradually increased to about 100 to 150 lbs. per sq. in., having the effect of compressing the air in the cells to a smaller volume and permitting about 10 to 12 lbs. of creosote per cubic foot to enter. The pressure is then released and the oil drained from the retorts; then a vacuum is produced, which causes the air within the cells to expand and forces the surplus oil out of the wood, leaving the wood fibres impregnated with from 4 to 6 lbs. of creosote per cubic foot. This process is best adapted for treatment of ties. The approximate time required using equalizing cylinders is:

	Hrs.	Mins.
Air to 80 lbs. pressure.....	0	30
Transferring oil	0	20
Creosote to 150 lbs. pressure.....	1	30
Maintaining 150 lbs. pressure.....	0	15
Forcing back oil.....	0	20
Vacuum	1	0
Maintaining vacuum	0	15
Draining	0	10
Total cycle	4	20

This time is based on thoroughly air seasoned ties.

Lowry Process.—This is often referred to as a partial cell treatment and it is used in connection with creosote oil. It consists of forcing creosote oil into the wood cells and then drawing out by vacuum the surplus oil, leaving only the wood fibres impregnated. The wood is first air seasoned in the open, then placed in retorts and submerged in creosote. The pressure is then applied by

forcing in additional creosote of 10 to 12 lbs. per cu. ft. at about 180 lbs. pressure so as to saturate the pores and cells, after which the retort is drained and a quick vacuum is produced and maintained from 1½ to 2 hrs., leaving the wood fibres impregnated with from 4 to 6 lbs. of creosote per cubic foot. This process is used principally in the treatment of ties. The approximate time required is:

	Hrs.	Mins.
Ties thoroughly seasoned:		
Creosote to 180 lbs. pressure.....	2	00
Draining oil from retort.....	0	10
Vacuum	2	00
Draining	0	10
Total cycles about.....	4	20

Card Process.—This process consists of impregnating the wood cells with an emulsion consisting of zinc chloride and creosote oil, as follows: The wood is first air seasoned in the open or steamed in the retorts (generally both) to reduce the moisture and expel the sap. Then a vacuum is produced and maintained for 1 hr., when the retort is filled with the hot emulsion consisting of ½ lb. of dry zinc and from 1½ to 4 lbs. of creosote per cubic foot. The pressure is then applied by forcing in additional emulsion at about 100 to 150 lbs. pressure per square inch, after which the retort is drained and a vacuum produced and maintained for about 30 min. to draw the surplus emulsion from the exterior of the wood to prevent loss by drippage when wood is removed from retort.

It is necessary to keep the emulsion constantly agitated to prevent a separation of the zinc and creosote and to accomplish this a centrifugal pump draws the emulsion from top of retorts and discharges into the bottom of the perforated pipe.

This process is used principally in the treatment of ties. The approximate time required is:

	Hrs.	Mins.
Steaming to 20 lbs. pressure.....	0	20
Steaming, 20 to 35 lbs. pressure.....	3	30
Blowing off steam.....	0	10
Vacuum ..	1	00
Emulsion to 120 lbs. pressure.....	1	00
Maintaining 120 lbs. pressure.....	1	30
Forcing back oil.....	0	15
Vacuum	0	20
Draining	0	10
Total cycle about.....	8	25

If the steaming time is reduced 2 hrs., then the cycle equals 6 hrs. 25 mins. If ties are thoroughly seasoned this time can be reduced to 4 hrs. 25 mins.

Cost of Treatment. The prevailing rates for treating material with these processes depend upon locality, structure of wood, condition of wood; that is, whether it has been air seasoned or requires steaming, residual impregnation and quality to be treated; however, it is safe to assume that the following is an average rate when taking creosote at \$0.07 per gal. and zinc chloride at \$0.04 per lb.

Process.	Per 7 x 9-in. x 8-ft. tie.	Per 1,000 ft. B. M.
Burnettizing $\frac{1}{2}$ lb. zinc chloride per cu. ft.	\$0.17	\$4.10
Wellhouse, etc.	0.28	5.50
Card	0.26	6.10
Rueping	0.32	7.60
Lowry	0.32	7.60
Absorption	0.32	7.80
Full cell	0.47	11.15

Cost of Creosoting and Life of Creosoted Timber.—Mr. O. T. Dunn gives the following data: Creosoting costs \$15 to \$20 per M. Assuming that two 6-ft. cylinders 100 ft. long are used, the capacity of each cylinder is 16,800 ft. B. M. The total plant will cost, say, \$80,000. If the timbers are to be impregnated with 20 lbs. of creosote per cu. ft., it will take about 36 hrs. for a run, and the annual capacity of the plant will be nearly 7,000 M. If the interest and depreciation of the plant is assumed at 10% we have $\$8,000 \div 7,000 = \1.14 per M. chargeable to this item. The labor will cost about \$3.75 per M. If the oil costs 8 cts. per gal., and 20 lbs. be used per cu. ft., the cost of oil is \$15.33 per M. This makes a total of \$20.22 per M. If 16 lbs. of oil per cu. ft. are used, the cost of oil is \$10.26 per M., thus reducing the total cost by \$5. If the plant is not worked to its full capacity, the interest charge per M. becomes greater.

Treated with 20 lbs. of oil per cu. ft., piles in the bridge of the L. & N. R. R., over the mouths of the Pascagoula river, have been in the structure 28 years, and will be good for many years to come. These piles are subject to attacks of the teredo, where uncreosoted piles $1\frac{1}{2}$ ft. in diameter have been cut off by the teredo in a single year.

Beech ties impregnated with 12 lbs. of oil per cu. ft. have lasted 30 years on the Eastern Railway of France.

Mr. Dunn underestimates the "plant charges," for while 10% for interest and depreciation, may be ample, it does not provide for current repairs. No data are available to determine what repairs will amount to, but I should put the item at less than another 10% of the first cost of the plant, excluding land and buildings.

Cost of Creosoting Ties.—Mr. W. H. Knowlton gives the following relative to a tie creosoting plant at Shirley, Ind. Ties are first seasoned 8 to 12 mos., then loaded on "buggies," 55 ties per buggy, running on 30-in. gage track made of 52 lb. rails, and hauled in trains of 15 buggies by an electric motor. There are 100 buggies. Two retorts, 7 ft. diam. \times 130 ft. long, receive these trains of ties, hence each retort holds 800 ties. The boilers are rated at 200 hp. The following force is required to work one shift:

- 1 man at the boilers.
- 1 headman in retort house.
- 3 assistants.
- 15 laborers to handle ties.
- 1 machinist.

When working at full capacity, two shifts are run. The laborers receive $\frac{1}{2}$ ct. for each tie handled.

Each tie receives about $2\frac{1}{2}$ gals. of oil, costing 6 cts. per gal. (in 1906), and having a specific gravity of 1.02 to 1.07, averaging 1.05 $\frac{1}{2}$. A chemist analyzes all oil. The charge for tie treating is 30 cts. per tie, including loading and unloading ties. This plant cost about \$75,000. Working only one shift per day, and allowing 5 hrs. for treatment of ties, the two retorts would handle 3,200 ties per day, or about 900,000 per year. Mr. Knowlton does not give the output but states that ties are left in the retort $3\frac{1}{2}$ to 6 hrs.

Cost of a Zinc Chloride Treating Plant.—A zinc chloride tie treating plant was built in 1902 at Carbondale, Ill., for the Ayer & Lord Tie Co. It has 8 cylinders or retorts, 6 ft. diam \times 125 ft. long, and the plant capacity is 2,000,000 ties per year, or 250,000 per retort. Each cylinder holds 14 iron cars, each with 30 to 40 ties, or about 500 ties. The buildings are of brick. The main building is 115 \times 123 ft., the retort room being 90 \times 123 ft. The boiler house contains six tubular boilers 6 \times 18 ft. The total cost of the plant is said to have been \$175,000, exclusive of yards and tracks. This is equivalent to about \$22,000 per retort, including buildings, etc., or about 90 cts. is invested in the plant per tie treated annually. See the section on Railways for other data on zinc chloride plant costs.

Ties Treated With Crude Asphaltic Oil.—On the A. T. & S. F. Ry. some seasoned pine ties were impregnated (in 1902) with California crude oil under a pressure of 150 lbs. per sq. in. Each tie took up 4 to 8 gals. of oil containing 77 $\frac{1}{2}$ % of asphaltum. After 5 years of service they were in first class condition, although untreated ties in the same locality (Southeastern Texas) lasted only 2 to 4 years on account of the heat and moisture.

General Data on the Cost of Framing and Erecting Timber.—A study of the data given in the subsequent pages of this section and in the sections on Buildings and on Railways will show that it seldom needs cost more than \$10 per M. to frame and erect almost any kind of a timber structure. In fact \$10 per M. is generally used by many contractors as a basis for a rough estimate of the labor cost of any timber work. Nevertheless, it should not be hastily assumed that labor on timberwork does not vary considerably in cost, depending on the character of the work. While it will rarely exceed \$10 per M. under good management, it may often be done for as little as \$1, and I have, in fact, had men lay plank roads for 50 cts. per M. These very low costs are obviously obtained only where there is no framing, measuring, or sawing, but simply handling and spiking the timber. Even in such simple cases, a little poor management may run the cost up to \$2 or \$3 per M.

I have made no mention of the rate of wages, for the cost per M. has been almost independent of rates of carpenters' wages. This seems incredible, but I find it to have been so, as a general

rule. Railway companies in America have long paid about \$2.50 per 10 hr. day to carpenters in shops and on bridge and building work. Contractors doing similar work often pay carpenters \$3.00 to even \$3.50 per 8 hr. day, and get the work done at less cost per M. than do the railway companies. The reason is not far to seek. By a process of natural selection the hard working, ambitious carpenters are soon found where higher wages prevail, and their hard work justifies the higher wage. It is the old story. Of course, it is also a fact that the average contractor is a much better manager than the average railway superintendent. That is why the one is a contractor and the other is a superintendent. This is not true of all individuals, but it is true of the classes taken as classes. The workman is usually worthy of his hire.

It does not follow, however, that labor unions may not force up wages without likewise forcing up the output of the workmen. This unfortunate condition—unfortunate, because it is against the best ultimate interests of the workmen themselves—exists in many cities.

Nor does it follow that it is not good economics to use common laborers as much as possible in heavy timber work. The usual mistake in management of timberwork is to let high priced carpenters do loading, carrying, cross-cut sawing, etc., which can be done just as well by common laborers.

Cost of Loading and Hauling Timber.—One man, assisted by the driver of a team, will load 1 M. of 2-in. plank onto a wagon in about 16 mins. These same two men will unload in 12 mins. With wages at 15 cts. per hr. per man, the cost of loading is 8 cts. per M., and unloading is 6 cts. per M. On short hauls, where the team is idle during the loading and unloading, it is necessary to add 7 cts. more per M. for lost team time, if the two horses are worth 15 cts. per hr. This makes a total of 21 cts. per M. for loading and unloading a wagon, including lost team time. Green timber weighs from 3 lbs. to 5 lbs. per ft. B. M., depending upon the kind. Assuming 4 lbs., as an average illustration, we see that 1 M. weighs 2 tons, which is a good load for hard earth roads in first-class condition. If the wages of a team and driver are 30 cts. per hr., and the load is 1 M., and the speed going and coming is $2\frac{1}{2}$ miles per hr., the cost of hauling is nearly 25 cts. per M. per mile measured one way from loading point to unloading point. On muddy earth roads, 1 ton, or $\frac{1}{2}$ M. is often a good load; then the cost of hauling is nearly 50 cts. per M. per mile. I have known earth roads to be so bad that hauling cost 75 cts. per M. per mile. Consult the index under "Hauling" for further data.

The cost of unloading timber from wagons can be entirely eliminated by having a roller 3 ft. long (or two 18 ins. long) at the rear end of the wagon box, and by tilting the wagon box up so that its front end is, say, 2 ft. higher than the rear end. The roller is provided with a ratchet wheel and a dog. Where the dog is tripped the timber rolls out of the wagon by gravity, if long sticks are on the wagon. If sticks are short, other rollers

must be placed in the bottom of the wagon box. All rollers are mounted in bearings, of course.

Sawing, Boring and Adzing.—In heavy timberwork the cost of framing consists mainly in sawing, boring and adzing the sticks. Where a large number of sticks are to be sawed to the same length it generally pays to install a small power saw; but on jobs of moderate size the customary practice is to frame the timbers with a cross-cut saw operated by two men. Using a sharp saw and working rapidly two men can cross-cut a 12 X 12-in. oak stick in 3 mins., but it is generally safer to allow 5 mins. to cover delays.

When a timber is to be notched, or scarfed, a cross-cut saw is used to cut to the bottom of the scarf, then a hatchet or adz is used to cut away the wood roughly, and an adz is used to dress the face. I have seen poor foremen permit workmen to use chisels instead of adzes, thus "making the job last."

A "dap" is a shallow notch cut in a stick.

Mortise and tenon joints are no longer used by those who know how to design economic and durable timber structures. Dowel pins and drift-bolts have largely replaced the old mortise and tenon.

In boring holes for bolts, there are three methods commonly used: (1) Boring by hand with ship augers; (2) boring vertical or inclined holes of moderate depth with hand-power boring machines; and (3) boring with augers operated by compressed air.

A man with a ship auger will bore a 1½-in. hole in oak, 12 ins. deep in 5 mins., or at the rate of 120 ft. in 10 hrs.

Using a geared boring machine, a man will bore a 1-in. hole 12 ins. deep in 2 mins., by hand, or at the rate of 300 ft. in 10 hrs.

With a pneumatic auger a man will bore a 1-in. hole 3½ ft. deep, in yellow pine chord members of a trestle, in 5 mins. of actual boring time, but 2 mins. more must be added for cleaning the shavings out of the hole, and moving to the next hole, making 7 mins. in all for 3½ ft., or 2 mins. per ft., or at the rate of 300 ft. in 10 hrs.

This is the most economic method of boring where much work is to be done. For cost of operating pneumatic machines, see index under *Pneumatic Machines*.

Mr. W. E. Smith states that in building an ore dock three pneumatic boring machines were used. The air was supplied by two 9-in. Westinghouse locomotive air pumps, through 1,200 ft. of 1½-in. pipe in one direction of the dock and through 1,000 ft. of 1½-in. pipe in another direction to the framing yard. For air receivers there were one locomotive air reservoir on the dock and one in the framing yard. The air pumps had to work so fast to supply air that a stream of water had to be kept running over their valves to keep them cool. It would require a 20 hp. boiler to supply steam for one of the air pumps working at such a speed. While these air pumps use a good deal of steam, they are very convenient, for they are light, easily moved and can be bolted up

anywhere to a wall or post. The pneumatic borers were run with a pressure of 60 to 90 lbs., and gave great satisfaction.

In the following paragraphs will be found a statement that in boring by hand, each man averaged 80 ft. of hole per day bored through trestle stringers, presumably $\frac{3}{4}$ or 1-in. holes, averaging less than 8 ins. deep.

For cost of boring deep holes lengthwise in oak piles, see the index under "Timber Boring."

In boring $\frac{3}{4}$ -in. holes with a ship auger through 12-in. Douglas fir, a man will ordinarily take 3 mins., which is at the rate of 200 ft. in 10 hrs.

Transporting Timber Short Distances.—Never allow carpenters to handle any considerable amount of timber. Provide common laborers for loading, carrying, etc. Rarely should men carry timbers on their shoulders or with lug hooks. Instead, lay run plank over which the timber can be pushed on a dolly, which is a little roller provided with a frame on which the timber is balanced. Often two dollies are used, one at each end of the timber. Even

Fig. 1.—Dolly with Handle.

if the timber is light boards, do not permit carrying, but require the boards to be stacked up on dollies.

I have found it advantageous to provide each dolly with a handle, as shown in Fig. 1. Then one man walks ahead pulling the front dolly by its handle, while another man follows at the rear pushing the handle of the rear dolly. The men walk tandem along the run plank until the place of delivery is reached, then, if it is a wooden bridge floor, they swing the rear end of the stick around (still on the dolly) and dump the plank right where it is needed by the carpenters. In loading such plank onto dollies, each man uses a lug hook. A 4 × 12 in. × 20 ft. plank weighed 250 lbs. Two men loaded, hauled, a distance of 60 ft., and delivered one plank every 1½ mins., or at the rate of more than 30 M. per 10 hr. day, or about 45 tons of lumber were loaded and transported 60 ft. by two men. A heavier load could readily have been handled on the dollies, but one plank at a time was more economic, since the carpenters were thus relieved of all work except spiking. In that connection I may add that each plank was pinched up tight against the last plank in the floor by a man using a peavey. Another man started each spike with an ordinary hammer, and two men drove the spikes with spike mauls.

Formulas for Quantity of Materials in Trestles.—I have deduced the following formulas from bills of materials of standard trestles on the Northern Pacific Ry.

High frame trestles are built in stories 25 ft. high. The following formulas give the amount of timber in a single-track frame trestle of any given height up to 125 ft.

(1) $M = L (220 + 6H)$ for trestles up to 25 ft. high.

(2) $M = L (240 + 8H)$ for trestles 25 to 50 ft. high.

(3) $M = L (240 + 9H)$ for trestles 50 to 75 ft. high.

(4) $M = L (240 + 10H)$ for trestles 75 to 125 ft. high.

M = total ft. B. M.

L = length of trestle in feet.

H = height from ground to 4 ft. below base of rail.

There are 164 ft. B. M. in the timber deck per lin. ft. of bridge, but the above formulas include this deck timber.

There are 70 lbs. of wrought iron and 20 lbs. of cast iron per 1,000 ft. B. M. of deck and half that amount per M. of bents.

Hence

(5) $W = L (20 + 0.4H)$ for trestles up to 75 ft. high.

W = weight of iron in pounds, 70% of which is wrought and 30% cast iron.

For closely approximate estimates determine the profile area of an opening that is to be trestled, calculating the area (A) from the ground up to a line 4 ft. below the rail. Divide this area (A) by the length (L) of the trestle, and the quotient is the average height (H). If it is desired to estimate quantities by profile area (A) direct, simply substitute for H in the above

equations its value $\frac{A}{L}$.

Equation (1) then becomes

(6) $M = 220 L + 6A$.

This has the same general form as my formula for the weight of steel in viaducts, which is given in the section on Bridges.

For pile trestles, four piles per bent (bents 16 ft. o to o) and assumed penetration and cut off of pile amounting to 20 ft., we have

(7) $P = \frac{H + 20}{4} \times L$.

(8) $M = 185 L$ for heights up to 15 ft.

(9) $M = 200 L$ for heights of 15 to 25 ft.

(10) $W = 16 L$.

P = number of lin. ft. of piles.

H = height of trestle in feet from ground to 4 ft. below rail.

L = length of trestle in feet.

M = ft. B. M.

W = weight of iron in pounds, 40% of which is wrought, 30% cast, and 30% galvanized.

The above formulas (1) to (4) for frame trestles are sufficiently accurate for all but very short trestles, but they give an excess of timber equivalent to the amount in one bent.

The formulas for pile trestles, however, provides for one bent fewer than is usually driven, for it is customary to drive an extra bent at each end to act as a bulkhead, and about 10 planks (4×12 in. \times 12 ft.) are placed as a sheeting back of each of these pile bulkheads, to hold back the earth fill. Hence one bent of 4 piles and about 500 ft. B. M. of bulkhead timber should be added to the quantities given by equations (7) and (8) for pile trestles, to be exact.

In the section on Bridges, it will be found that the average height of trestles on the Great Northern and on the Northern Pacific Rys. in Washington was a little less than 20 ft. In which case $H = 16$, and eq. (1) gives us

$$M = (220 + 96) = 316 \text{ ft. B. M. per lin. ft.}$$

$$W = (20 + 6.4) = 26.4 \text{ lbs. iron.}$$

Hence at \$20 per M. for timber in place and 4 cts. per lb. for iron in place, the cost is \$10.55 per lin. ft. of trestle.

The following is the bill of lumber in a Northern Pacific pile trestle per 16 ft. length.

	Ft. B. M.
6 stringers, 9×18 -in. \times 16-ft.....	1,296
3 packing blocks, 4×18 -in. \times 6-ft.....	108
1 spacing block, 4×6 -in. \times 6-ft.....	12
14 cross ties, 8×8 -in. \times 12-ft.....	896
2 guard rails, 5×8 -in. \times 16-ft.....	107
1 cap, 12×16 -in. \times 14-ft.....	224
3 lateral braces, 6×8 -in. \times 18-ft.....	144
1 cleat, 3×8 -in. \times 10-ft.....	14
2 sway braces, 3×10 -in. \times 20-ft.....	100
Total	2,901

This is practically the constant for heights (H) up to 15 ft., and is equivalent to 186 ft. B. M. per lin. ft. But above that height is customary to put a horizontal brace midway between the cap and the ground, and use four diagonal sway braces instead of two.

Methods and Cost of Building a Railway Trestle.—A trestle on the Indiana, Illinois & Iowa R. R., near Streator, Ill., was destroyed by a tornado in July, 1903. The right-of-way was quickly cleared by a large gang of trackmen and a new trestle built, using about half of the old timber, all of which had to be framed over again as the bents were made of different heights. The new trestle was 354 ft. long, consisting of 60 bents spaced 14 ft. center to center. Of these bents 43 were double-deck bents, the upper bents being $20\frac{1}{2}$ ft. high, and the lower bents averaging 21 ft. The remaining bents were single-deck. The force averaged 70 bridgemen (carpenters), and 190 trackmen (laborers), and a few teams. This force cleared away the wreckage, and built the new trestle complete in 7 days, not including $1\frac{1}{2}$ days spent in getting men to the site of the work. There were 351,000 ft. B. M. in the new trestle, including ties, and the cost of clearing the site and building the trestle was \$11.85 per M. for labor of bridgemen, trackmen and a few teams. The wages were probably about \$1.50 per 10-hr. day for trackmen, and \$2.50 for bridgemen. The new timber cost \$27 per M.

The mortise and tenon is "a back number" on railway trestle work, so the principal tools used were the two-man cross-cut saw, the adz, and the ship auger. The sills were dapped $\frac{1}{2}$ -in., and the ends of the posts were framed to $11\frac{1}{2}$ ins. square, ensuring a perfect joint.

The posts were sawed off square, dapped into the cap and drift-bolted, toenailed to the sill with eight $\frac{3}{4}$ -in. \times 10-in. boatspikes in each post.

A peg was driven and numbered to mark the center of each bent, and small stakes were set on each side to mark the location of the plumb legs and batter posts. The ground was then dug to a level surface around each of the four pegs, but no particular care was taken to dig the ground to the same level at all four pegs. Differences in level were made up by using blocks for cribbing under the sills. These blocks were leveled on top by digging earth out from under them where necessary, which did away with adzing or shimming the sill. The blocks under each bent consisted of eight pieces 4 ft. long, two blocks under each post, giving a ground bearing of about 45 sq. ft. per bent.

When a foundation of blocking and the lower sill were in place, the posts and cap for a bent were dragged by teams to the site of the bent and rolled over into position just ahead of the foundation. The sill was rolled over on its side; the plumb posts were butted against the dapped places and toenailed, being centered from the grading pegs. The batter posts were laid near their proper places (but not toenailed), and the cap was drift bolted to all four posts, holes having already been bored in the cap. The cap and sill were held tight to the plumb post with chains and with "right and left screw-pulling jacks." Then the batter posts were crowded in at the bottom and toenailed to the sill. The bent being assembled, one sash brace and two sway braces were spiked across the upper face of the bent as it lay blocked up a few feet above the ground. Four $\frac{3}{4}$ -in. \times 8-in. boat spikes were used at each intersection. The bent was then ready to be raised. A set of double tackle blocks was made fast at each end of the cap and anchored to the cap of the preceding bent which had already been erected and securely braced. The pulling ropes ran through snatch blocks fastened to the sill of this preceding bent, and a team was hitched to each of the two pulling ropes. The team up-ended the bent easily. A subbing rope around the cap, and anchored to any convenient anchorage, prevented the bent from going too far and tipping over. And two temporary struts from the sill of the preceding bent to the sill of the bent that was being raised, prevented the bent from sliding while being raised. When erected, the bent was pinched over so as to be centered on the alignment stake; then plumbed and tied to the preceding bent with sash braces and sway braces. The bents were plumbed by eye, or by lining the posts up with a plumb line string held at arm's length. It was necessary to plumb the bent from both sides. A small gang followed the erectors, putting

on the remaining sash braces, sway braces, tower braces and A-braces.

Teams were used for hoisting the framed timbers for the top series of bents, from the ground to the top of the lower series of bents, where they were assembled and erected practically as above described. To hoist the timbers for the top series of bents, a gin-pole was erected. The gin-pole was 40 ft. high, and consisted of two 8 X 12-in. pieces, 28 ft. long, with another piece spiked between them so as to give a total length of 40 ft. This gin-pole was securely chained to one of the lower bents. At first a series of match blocks was used in hoisting the timbers, but this proved too severe on the teams and double blocks were used to multiply the power.

The 8 X 16-in. stringers were run out on the trestle on dollies pushed along run planks. They required but little framing. The ends were cut off so that the joint came over the middle of the cap, and the end of any stringer more than 15½ in. deep was adzed off to that size, to give an even bearing for the ties. The stringers were then turned over flatwise, and piled three deep (breaking joint) and bored. Then they were lifted apart and 2-in. cast iron packing washers slipped in between, and the bolts were entered and tightened. Sections of stringers 200 to 300 ft. long were bolted together, and then turned over into position. To turn a section over, a stout lever, 10 ft. long, was chained to one end of the section. A set of double blocks and tackle fastened to the end of this lever quickly turned the section over.

In boring the holes through the stringers each man averaged 80 ft. of holes bored per day, that is 40 holes 2 ft. long.

The ties were hoisted from the ground by teams, using gin-poles.

The foregoing description has been prepared from data given by Mr. W. R. Sanborn.

Cost of a Timber Viaduct.—Mr. S. D. Mason gives the following data relating to a high timber viaduct on the N. P. R. R. in the Rocky Mts., near Missoula. The viaduct contained 970 M. of Norway pine, 75% of which was sawed by contract and the rest hewed. The saw mill was put up near the work and all the timber was framed at the mill. The viaduct was 886 ft. long, and 327 ft. high for a distance of about 150 ft. at the center. It consisted of 8 timber towers supporting 7 Howe truss spans of 50 ft. each. On each side of these were M bents supporting straining beams of 80 ft. span each. The timbers were erected by 2 to 4 gangs of 16 men each, a stick at a time. The heaviest stick weighed 1,700 lbs. Both horse and steam power were used for hoisting. The chords of the Howe trusses consisted of two 6 X 12's and one 8 X 12. They were placed and the diagonal braces put in, beginning at the center, the chords being temporarily held by struts and guy lines. It was found impracticable to raise the trusses bodily. Fir angle blocks were used, but their subsequent shrinkage led finally to the building of new Howe trusses. Work was begun Jan. 1, 1882, and completed in 171 days. Laborers and carpenters received

exceedingly high wages, \$6 to \$7.50 a day, which accounts for the high cost of \$87 per M. for framing and erecting. At ordinary wages the labor would have cost about \$12 per M. The erecting gangs struck for \$10 a day when within 30 ft. of the top, and their wages were raised, but it is not stated how much. The following was the cost of the viaduct:

869 M., at \$27.....	\$23,463
101 M., at \$16.....	1,616
37,120 lbs. wrought iron, at 5% cts.....	5,010
29,940 lbs. cast iron, at 3% cts.....	973
117,060 lbs. hauled 80 miles, at 2% cts.....	3,320
Wages of carpenters and laborers.....	26,326
Salaries of engineers.....	3,137
Traveling, office and sundry expenses.....	1,907
Supplies for men.....	2,860
Blocks, ropes, chains and wrenches.....	1,300
40 horses, 90 days, at \$1.....	3,600
Hay and oats for same.....	2,700
Rent of land and land damages.....	400
Total, at \$88.27 per M.....	\$85,623

Cost of Building a Pile and Timber Approach to a Bridge.—Mr. B. L. Crosby gives the following cost data on the building of a timber trestle approach, 2,960 ft. long, to a double track bridge across the Missouri River, in 1893. The trestle was built by company men. In the trestle there were 1,438 M of yellow pine, 35,220 ft. of piles, and 97,552 lbs. of iron (70 lbs. per M of timber). The cost of unloading, handling and driving piles, including all material and labor (except the cost of the piles themselves) was 13.7 cts. per lin. ft. The cost of unloading, framing and erecting timber, was \$7.42 per M.

Cost of Building a Trestle and a Howe Truss Bridge Under Traffic.—An old railway trestle was rebuilt under a traffic averaging one train per hour. The trestle was 300 ft. long and 50 ft. high at the center. The labor of rebuilding this trestle cost \$9.90 per M, including taking down and piling up the old trestle timbers. There were 5 men and a working foreman in the gang; 2 men at \$3 a day each, 3 men at \$1.75, and 1 foreman at \$60 a month.

This same gang built a Howe truss railway bridge under traffic at a cost of \$28 per M for labor. The cost of framing and placing 20 M of oak ties and guard rails on three bridges was \$12 per M, which was a very high cost. For comparative data see the section on Bridges.

Cost of Wagon Road Trestles.—My records show the following costs of building a dozen or more trestles in the state of Washington. The trestles were for highway use, and had a 3-in. plank floor, 16 ft. wide, resting on 7 lines of 4 x 14-in. stringers. Bents were spaced 20 ft. apart, three 10 x 10-in. posts to a bent dapped into and doweled to caps and sills. Sills were of hewed cedar 10 x 15 ins. Caps were 10 x 12 ins. x 18 ft. Sway braces were of 3 x 6-in. stuff spiked to the posts and sill. The supports for the hand rail consisted of 4 x 4-in. posts, 4½ ft. long, spaced 10 ft. apart and bolted to the outer stringers which in turn were drift bolted to the caps. The top or hand rail was of 3 x 4-in. stuff, and the hub rail was 3 x 8 ins.

There was no mortise and tenon work, and the framing was of the simplest type. The bents were framed flat on the ground and up-ended to place by using blocks and tackle operated by hand power. The flooring and stringers were conveyed to place by dollies. The work was done by subcontractors with few carpenters, and in all cases was handled with excellent judgment and with rapidity.

To frame and erect a trestle 60 ft. long, consisting of two bents and two bank sills, required 4 men only $1\frac{1}{2}$ days. This trestle contained 7 M, of which 5 M were in the floor system (floor and stringers). Three of the gang were laborers, at \$1.50, and one was a carpenter, at \$2.50, making the daily wages \$7 for the gang, so that the cost of building this trestle was only \$1.50 per M. This cost was distributed as follows: \$4 per M for framing and erecting the bents and the hand railing; 50 cts. per M for laying the stringers and the floor plank. This laying of stringers and plank, where there is nothing to do but to deliver them on dollies, toenail the stringers to the caps, and spike the floor plank to the stringers, can be done very cheaply by common laborers skilled enough to drive nails.

It is not necessary to notch the stringers in order to secure alignment of the tops of the stringers for the plank floor, because in such timberwork perfection of alignment causes a needless waste of labor.

A gang of 2 laborers, on another trestle, laid a floor system containing 15 M of plank and stringers in $1\frac{1}{2}$ days, at a cost of 50 cts. per M.

On another trestle 260 ft. long, it took 4 men 3 days to lay 23 M of stringers and plank in the floor system, at a cost of nearly \$1 per M. These men were much slower.

On another piece of road work, where we used round timber for the posts and sills, a gang of 9 men and a team cut and delivered all the necessary timber from the forest, erected and sway braced the bents of three trestles, having a total length of 440 ft. in 12 days. There were 7 framed bents, 12 pile bents (36 piles 20 ft. long, driven 5 ft.), and 6 mud sills in these 3 trestles. The piles were driven with a small horsepower pile driver. Seven of these men were laborers, two were carpenters and bosses. The timber in the bents was not accurately measured to determine the number of board feet, but the approximate cost, including the piles, was less than \$16 per M for the bents. The cost of the sawed timber floor system was, of course, much less. I consider this an excellent record, and one not to be equalled except under the best foremanship and with willing, intelligent laborers.

Cost of Trestles, Cross References.—For further data on trestles see particularly the section on Railways. Consult the index under "Timber, Trestles."

Estimated Prices of Howe Truss Bridges.—The following were detailed estimates of cost at standard contract prices for building Howe truss single-track bridges in Washington (in 1906), according

to standard plans of the Northern Pacific Ry. All lengths are lengths over all.

40 FT. PONY TRUSS BRIDGE.

Materials.

15 M. timber at \$16 + \$2 frt. = \$18.....	\$ 270
2,500 lbs. wrt. iron at 3 cts. deliv.....	165
2,200 lbs. cast iron at 2½ cts.....	55

Total abutments, \$7.70 per lin. ft.....	\$1,150
Grand total, \$47.20 per lin. ft.....	7,102

The standard pile abutment contains 14 piles for spans under 80

ft., 16 piles for 80 to 120-ft. spans, and 20 piles for 120 to 160-ft. spans. Obviously the cost of piles will vary with the length. It is customary to assume a 20-ft. penetration. In addition to the piles there were 2,500 to 4,000 ft. B. M. of timber per abutment, and 100 lbs. of iron per M of this timber.

It will be noticed that the cost of Howe truss bridges on pile abutments does not vary greatly per lin. ft. of span, the principal reason being that the abutments constitute so large a part of the cost.

See the section on Bridges and on Railways.

Cost of 160-ft. Span Howe Truss Bridges and Cribs.—In 1904 I designed, and built by contract, two highway bridges over different points on the Nooksack River, Washington. Each bridge had a 14-ft. roadway, a clear span of 160 ft., and a depth of truss of 30 ft. at the center. The bridge was designed to carry 100 lbs. per sq. ft. of roadway. The trusses were a modified type of Howe truss, having upper chords that were not horizontal but sloped up from both end posts to an apex at the center, like a roof truss. This design very materially reduced the amount of iron, which was an important factor. Each chord was made of three parallel timbers, each 8 x 14 ins., bolted together. Panels were 20 ft. long. The floor was of 2-in. cedar plank, for lightness and durability. The rest of the timber was Washington fir. The bridges rested on pile abutments, which were protected by log cribs filled with field-stones. Each bridge contained 40 M of timber, of which 23 M were in the trusses and braces, and 17 M in the floor system.

No piles were driven for falsework, although the river was 4 to 8 ft. deep and swift; but two-post bents were put up just back of each panel point. Bents were made of round timber, and erected by first dropping into the water pairs of long-legged saw horses on each side of the proposed falsework, and laying run planks on the horses for men to walk on. A falsework can thus be built with great rapidity and cheaply, and in spite of the weight coming upon the posts of each bent the settlement in the gravel bottom was very slight, and easily taken up by wedges under the lower chords. There is always danger, however, that a sudden flood will undermine the falsework, and this happened at one of the bridges, causing it to fall during construction.

No upper falsework, except a light staging at each end post and at the center, is needed with this type of truss, provided long sticks of timber can be secured; for with chord sticks 63 ft. long (in a bridge of this size) it is possible to lift, first one end, then the other, of the upper chord sticks and support them upon the light staging at each end, until the diagonal struts are placed.

The trusses must be first framed and bolted together, flatwise on the ground, then unbolted and erected piece by piece. The timbers were pushed out onto the falsework on dollies, and lifted with block and tackle, using a gin-pole where necessary; all this handling being by hand without a hoisting engine. Although the following record of low cost will be hard to equal, it serves to show what can be done with efficient labor under a good bridge foreman.

COST OF 160-FT. SPAN BRIDGE.

Materials	
40 M. timber, at \$7 on cars.....	\$ 280.00
40 M. timber hauled 3 miles, at \$2.50.....	100.00
2,970 lbs. iron rods; 662 lbs. bolts; 769 lbs. gib plates; 326 lbs. drift bolts; total 5,727 lbs., at 3¼ cts.....	186.10
14 cast iron angle blocks, 1,316 lbs., at 2¼ cts.....	36.20
613 cast iron washers, 613 lbs., at 2¼ cts.....	15.80

Total	\$ 637.00
Foreman, at \$4 per day.....	160.00
Grand total labor on bridge and abutments..	\$ 797.00
Summary	
Bridge materials delivered.....	\$ 642.00
Piles delivered.....	45.00
Labor	637.00
Foremanship	160.00
Tools, ropes, etc. (one-half charged to each bridge)	100.00
Total cost of one bridge and abutments....	\$1,584.00

This is less than \$10 per lin. ft. of bridge.

Deducting the cost of material and labor on the two pile abutments and their cribs, we have left, \$1,200 as the cost of one bridge alone.

If we analyze the labor we find that the wages of the foreman amounted to 30% of the total labor expenditure. This is a high percentage, but one often exceeded on small works of this character where delays due to bad weather or lack of materials, add up very rapidly when the foreman is paid by the month for handling a small gang of men.

It will be seen that the carpenter work of framing the 23 M (exclusive of the floor) cost \$4.50 per M, to which should be added about \$1.00 per M for foreman. Erecting the bridge (exclusive of 17 M of floor) cost \$133 after the falsework was built, or nearly \$6 per M (4 erectors being carpenters, at \$2.50, and 6 laborers, at \$1.50), to which should be added \$1.50 for foreman. This makes a total of \$10.50 per M for framing and erecting the 23 M in the bridge trusses, to which must be added \$2.50 per M for foreman, and \$2 more per M for erecting falsework, if we distribute the

labor cost of erecting the falsework over the 22 M. The falsework cost must be estimated for every bridge separately. In this case it was unusually cheap.

The cost of placing the 17 M of flooring on the bridge was less than \$1 per M, for there was practically no sawing, adzing or boring to be done—simply running the timber out to place on dollies, and spiking it. This seems an exceedingly low cost, but similar records will be found on other pages. Perhaps no better example will be found in this book to show the necessity of separating plain timber work from framed timberwork in analyzing timberwork costs.

The cost of the pile driving was high per pile not only because the driving was very hard, but because of the small number of piles in each abutment, and because of the cost of moving across the

Fig. 2.—Log Culvert.

river and erecting staging for the driver to rest upon at each abutment.

The cribs around the piles were made of hewn timber taken from the forest near by. Each crib averaged 8 ft. high, 10 ft. wide, and 30 ft. long, containing about 8 M of timber. The cost of cutting this timber, hewing and erecting it, was \$6 per M, wages of men being \$2.50 a day. To this about \$1.50 per M. should be added for foreman.

A third crib, built for another bridge abutment, was 10 ft. high, 12 ft. wide, and 35 ft. long, containing about 12 M of hewed timber. It took 5 men 4 days, at \$2.50, to cut the timber for and build this crib, which is equivalent to about \$4 per M and to this \$1 per M should be added for foreman.

For actual cost of Howe truss railway bridges, see the section on Bridges.

Cost of Log Culverts.—In building roads and railways through timbered country, it is generally good practice to build most of the culverts of logs. Log culverts are frequently floored with logs for the full length of the culvert, but they may be built with log sills spaced 4 ft. c. to c., and projecting 1 ft. beyond the walls, as indicated by the dotted lines in Fig. 2.

The ends of a log culvert are stepped up, as in Fig. 2, $L = L - 2D$. Hence the "average length" is $L - D$.

To estimate the lin. ft. of logs in a paved culvert like that in Fig. 2, add 2 ft. to the inside horizontal dimension to get the length of

logs in pavement and in cover, which is 6 ft. in this case. Then double this length and add double the inside height; the sum will be the total lineal feet of 12-in. logs per lin. ft. of "average length" of culvert. In a 2 x 4 culvert (Fig. 3), this gives $(2 \times 6) + (2 \times 2) = 16$ lin. ft. of logs.

There are 0.3 lb. of $\frac{3}{4}$ -in. drift bolts required per lin. ft. of logs (or 25 lbs. per M when squared timbers are used).

The bidding price is usually about 12 cts. per lin. ft. of logs in place, plus 3 cts. per lin. ft. for hewing two sides, exclusive of the price for the iron. On the Great Northern Railway (517 miles) in

Fig. 3.—Log Culvert.

Washington, the average size log culvert was $3 \times 3\frac{1}{2} \times 43$ ft., or 750 lin. ft. of logs per culvert, and I estimated the average contract price in place to be:

	Per. lin. ft. logs.
Logs in place.....	\$0.12
Hewing $1\frac{1}{2}$ sides at $1\frac{1}{2}$ cts. per side.....	0.02
0.33 lbs. iron drift bolts at 3 cts.....	0.01
Excavating 0.04 cu. yds. at 25 cts.....	0.01
Total	\$0.16

See the sections on Railways and on Bridges.

Materials Required for Timber Box Culverts.—Culverts made of sawed timber are usually designed much lighter than log culverts. A 8×4 -ft. opening will have wall pieces 8 ins. thick (8×12), cover 8 ins. thick (8×12), sills 4 ins. thick (4×12) spaced 4 ft., c. to c., and floor 2 ins. thick (2×12), making a total of 90 ft. B. M. per lin. ft., and requiring 25 lbs. of drift bolts per M.

Cost of a Wooden Reservoir Roof on Iron Posts.—A reservoir at Pasadena, Cal., was roofed over in 1899, at a remarkably low cost. I am indebted to Mr. T. D. Allin for the following data: The extreme dimensions of the reservoir were 330×540 ft., and 166,000 sq. ft. were roofed. The roof was supported by 551 iron posts made of 2-in. water pipe, capped at the bottom and set in cement. On the top of each of these posts a wooden corbel, 6×6 ins. $\times 2\frac{1}{2}$ ft., was fastened by boring a hole 4 ins. deep in the corbel and driving the pipe into the hole. Each post, about 20 ft. long, was up-ended by hand, after the corbel had been driven on, plumbed and tempo-

rally stay-lathed. Posts were spaced 15% and 18 ft. apart. On the posts were laid floor beams made of two 2 x 10-in. plank, overlapped at the ends and spiked together, forming a continuous beam 4 x 10 ins. A gang of 7 men, using movable scaffolding for placing and spiking these floor beams, averaged 1,500 ft. of floor beams per day. On these beams were laid 2 x 8-in. stringers, 16 ft. long. The stringers were overlapped 4 ins. and spiked, and were spaced 6 ft. centers. On the stringers were laid 1 x 12-in. planks, forming the roof. These planks were cut to 12-ft., 18-ft. and 24-ft. lengths, the planks being laid in forms so as to facilitate accurate cutting without individual measurement of each plank. Similar forms were used for cutting the planks used in the floor-beams. The stringers did not require accurate cutting. All the timber was rough, merchantable Oregon pine. The cost of this roof, covering 166,000 sq. ft., was as follows:

260 M. Oregon pine, at \$18.70.....	\$4,862
9,373 ft. of 2-in. pipe.....	987
Nails and spikes.....	203
Millwork on 551 corbels.....	27
Cement for footings.....	6
Engineering	151
Labor, including superintendence.....	1,004

Total, 166,000 sq. ft., at 4.36 cts.....\$7,240

It will be noted that the labor cost was about \$4 per M. Mr. Allin informs me that about 75% of the work was done by laborers and 25% by carpenters. The laborers received \$1.75 for 9 hra., and the carpenters, \$2.50 for 9 hra. The work was done during hard times and quite a number of the laborers were really carpenters. Carpenters were used on the erection work and on work around the sides of the structure where neatness was required.

More recently Mr. Allin has completed covering three more reservoirs in a similar manner, the only change in design being the spacing of joists 4 ft. apart instead of 6 ft. He believes that the extra expense is justified because there is less warping of the boards. Wages are now (1905) \$4 per 9 hra. for carpenters, and \$2 for laborers, and prices of materials are higher, so that it costs 6 cts. per sq. ft. to cover a reservoir.

For other data on reservoir roofs see the section on Waterworks.

Cost of a Crib Dam.—Mr. J. W. Woermann gives the following cost data for two crib dams across the north and the south channels of Rock River, at the head of Carr's Island, near Milan, Ill., built in 1894. The north dam is 598 ft. long; the south dam, 764 ft. long. The two dams are connected by a levee 1,000 ft. long. The dams are on a rock foundation, and designed to withstand a head of 4½ ft. The dam is a crib of 6 x 8-in. pine timbers, with a rock filling. The main part of the dam is 13½ ft. wide, with an apron 6½ ft. wide, making a total base of 20 ft. A filling of clay and quarry refuse is placed against the cribwork on the up-stream side. The main dam and the apron are covered with 4-in. oak plank, and the up-stream face of the dam with two rows of 2-in. pine sheet-piling. From the crest of the dam to the apron the fall is 3 ft.

An area below the north abutment was stripped for a quarry (June, 1894), and the 800 cu. yds. of stripping, together with 300 cu. yds. of riprap, were used for cofferdams for the north dam. The cofferdams were made as follows: Cribs, 16 ft. square, were built in line, spaced 14 ft. apart. The cribs were built in shallow water by boring holes in the ends of each timber and dropping the timbers over long upright bolts at each corner of the crib. The top of these cribs was sheeted with 4-in. oak plank and weighted down with bags of sand. Timbers, 8 x 8-in., the ends of which were supported by adjacent cribs, were then shoved down into the water. This furnished a cofferdam 120 ft. long, and riprap and quarry stripping dumped against the face of the dam could not be washed away. The 4-in. oak plank was then removed and used in the permanent work. Subsequently the riprap, which was placed on the downstream side of the cribs, was removed and used in the dam. The quarry stripping was placed on the up-stream side of the cribs. The areas enclosed by cofferdams were 50 to 200 ft. long, and were kept dry with hand pumps. The water in the river was so shallow that wagons were used to deliver all the materials used in both cofferdams and main dams.

The carpenter work on the south dam was begun Aug. 7 and finished Aug. 22, working 8 hrs. a day, including Sundays. For this dam about 75% of the rock was quarried from the river bed without requiring explosives. During the construction of the cofferdam for the south dam the force was 14 teams and 50 laborers (for a few rush days there were 130 laborers), and they were engaged from July 24 to Aug. 4. During the erection of the cribwork for the main dam (16 days) the force was 16 carpenters and 50 laborers, about one-third of the laborers assisting the carpenters in carrying timbers, boring, driving bolts and spikes. The number of teams was the same throughout the work.

The total amount of timber in both dams was 330,190 ft. B. M., distributed thus:

	Feet B. M.	
	North dam.	South dam.
Longitudinal timbers (pine).....	47,230	73,550
Transverse timbers (pine).....	28,350	48,950
Sheet piling timbers (pine).....	7,950	14,610
Plank in cooping (oak).....	33,540	42,840
Plank in apron (oak).....	15,870	19,300
Total	132,940	197,250

The cost of the labor of putting this timber into the dams was \$5.80 per M.

The rock filling in the north dam is 1,240 cu. yds.; in the south dam, 2,350 cu. yds. The iron used was:

	North dam.	South dam.
Anchor bolts, lbs.....	1,010	320
Drift bolts, lbs.....	6,050	9,610
Boat spikes, lbs.....	4,750	6,050
Wire nails, lbs.....	300	400
Total, lbs.....	12,110	16,380

The cost of labor on the two dams was:

	North dam.	South dam.
Hauling materials.....		\$ 284
Building coffer-dams.....	\$ 730	1,055
Preparing foundation.....	493	818
Carpenter work on dams.....	949	965
Quarrying rock, filling cribs and grading above dams.....	1,966	1,971
Engineering, watching and miscel- laneous	362	402
Total	\$4,500	\$6,495

This makes the total cost of labor \$9,995 on the two dams. The total cost was as follows:

Labor	\$ 9,995
Rent of land.....	217
111 M. oak.....	2,919
218 M. pine.....	3,087
28,490 lbs. iron.....	805
Explosives	151
Total	\$17,174

Cost of Timber Cribs for Dams, Etc.*—Maj. Graham D. Fitch gives the following:

Timber cribs were built in connection with the building of the lock described on page 989.

The work was done on the Upper White River, Arkansas, by Government forces, common laborers receiving \$1.50 per 8-hr. day.

Guide Cribs.—At the head and foot of each lock wall permanent guard or guide cribs were placed. The upper river crib is a solid crib, containing the line of the river wall. It is 150 ft. long and 8 ft. wide on top. The inside face is vertical from the top to 1 ft. below the upper miter sill, below which it is stepped, as is the outer face, so that the width of the base 30 ft. below the top is 20 ft. The lower part of the crib work connects with the lock wall, but above a level 2 ft. below the upper miter sill there is a gap 10 ft. wide between the crib and the lock wall for the passage of drift. The top of the crib is level with the coping.

The lower river crib is 150 ft. long and is similar to the upper crib except that there is no gap between the crib and the lock walls, and that the top of the crib is not level with the coping throughout, that portion farthest down stream being 5 ft. below the coping in elevation.

The land cribs are in line with the lock walls, the upper one being 66 ft. long and the lower one 20 ft. The cribs were built of 10 x 10-in. timbers, framed and drift bolted together, pine being used below pool level and oak above. The cribs are filled with one-man stone, large selected stones being set on edge with their flat faces against the side openings, the top being covered with large, well-shaped stones set level with the timbers.

**Engineering-Contracting*, May 6, 1908, p. 283.

The cost of the upper land crib was as follows:

Material.	Unit cost.	Total.	Per M. ft. in crib.
Lumber, pine, 30 M. ft. B. M.....	\$18.20	\$ 546	\$80.20
Riprap, 602 cu. yda.....	.74	445	14.83
Iron, 2,360 lbs.....	.0026	63	2.10
Total materials.....		\$1,054	\$35.13
Labor.			
Excavating 45 cu. yda... ..	\$ 1.88	\$ 85	\$ 2.83
Insp. of timber, 30 M. ft.....	.39	12	.40
Riprap, 602 cu. yda.....	.008	5	.16
Building and filling, 30 M. ft.....	15.42	463	15.42
Backfill, 180 cu. yda.....	.526	95	3.14
Total labor.....		\$ 860	\$21.98
Grand total (30 M. ft.).....		\$1,713	\$57.10

The labor items in the above work that can be further summarized are as follows:

Work done.	Labor time in days.	Work done per man per day.
Excavating, 45 cu. yda.....	46 7/8	.957 cu. yd.
Building and filling, 30 M. ft.....	259 6/8	.115 M. ft.
Backfilling, 180 cu. yda.....	44 4/8	.404 cu. yd.

The cost of the lower land crib was as follows:

Material.	Unit cost.	Total.	Per M. ft. in crib.
Lumber, pine, 9.3 M. ft.....	\$18.15	\$169	\$18.15
Riprap, 146 cu. yda.....	.74	107	11.51
Iron, 413 lbs.....	.026	11	1.12
Total materials.....		\$287	\$30.78
Excavation labor.			
Earth 92, rock 15, 107 cu. yda... ..	\$ 3.26	\$242	\$26.02
Building and filling, 9.3 M. ft....	...	275	29.65
Insp. of timber, 4 M. ft.....	.39	3	.21
Inspection of riprap, 65 cu. yda..	.008
Total labor.....		\$519	\$55.88
Grand total (9.3 M. ft.)		\$806	\$86.66

The following is the cost of the lower river crib:

Material.	Unit cost.	Total.	Per M. ft. in crib.
Lumber, oak, 14.3 M. ft. B. M....	\$16.82	\$ 249	\$ 5.39
Lumber, pine, 31.3 M. ft. B. M....	14.97	469	10.16
Riprap, 1,014 cu. yda.....	.74	714	16.46
Iron and spikes, 5,420 lbs.....	...	132	2.86
Fuel	21	.45
Total cost materials.....	...	\$1,585	\$34.33
Labor.			
Excavating, 930 cu. yda.....	\$ 0.039	\$ 39	\$ 0.84
Framing and placing timbers, 46.2 M. ft.....	15.60	721	15.60
Filling with riprap, 1,014 cu. yda.	.447	455	9.85
Inspection of lumber, 8 M. ft.....	.39	3	.06
Inspection of riprap, 90 cu. yda...	.008	.72	.02
Total labor.....		\$1,219	\$26.37
Grand total (46.2 M. ft.)....		\$2,804	\$60.69

The cost of the upper river crib was as follows:

Material.	Unit cost.	Total.	Per M. ft. in crib.
Lumber, oak, 15.6 M. ft. B. M....	\$20.12	\$ 314	\$ 6.60
Lumber, pine, 32 M. ft. B. M....	14.90	477	10.02
Iron and spikes, 1,620 lbs.....	.028	46	.93
Riprap, 1,315 cu. yds.....	.74	973	20.47
Total cost materials.....		\$1,810	\$38.02
Labor.			
Excavation		\$ 60
Framing and placing timbers, 47.6 M. ft.....	\$10.22	\$ 491
Filling with riprap, 1,135 cu. yds.	.81	410
Total labor.....		\$ 961	\$19.98
Grand total (47.6 M. ft.)....		\$2,761	\$58.00

The average costs of crib materials may be summarized as follows:

	Per cu. yd.
Average cost of riprap, delivered.....	\$.74
Average cost to place.....	.436
Average cost in place.....	1.176
	Per M. ft.
Average cost of crib timber, delivered.....	\$13.82
Average cost to place timber.....	8.29
Average cost of crib timber in place.....	22.11

The above costs include field supervision and subsistence, but do not include freight on timber, which is about \$1 per M. ft.

Crib Dam.—Dam No. 1 was a timber crib structure placed normal to the axis of the river and resting against the buttress of the upper river lock gate, so as to have the whole length of the lock chamber in the lower pool. The dam was 324 ft. long. For the 210 ft. next to the lock it is founded on rock, the remainder of it resting on gravel. The width at the foundation is 48 ft., and the height above the foundation varies between a maximum at one place of 27 ft. (on rock) and a minimum of 19 ft. next to the old abutment. The cribs are of yellow pine except the slope timbers and the face stringers, which are of white oak. All timbers are 10 x 10-in. scantling and are drift bolted together at their intersections. The up-stream face of the dam is vertical to within 2 ft. of the top, whence, to prevent catching drift, it slopes to the crest (a 12 by 12-in. comb stick), having a slope of 1 on 4. The down-stream face sloped from the crest for 8 ft. with a slope of 1 on 4 and was stepped, having two steps each 8 ft. wide and an apron 16 ft. wide, the three vertical intervals being four courses of 40 ins. each. The upper slope was laid closely so as to be water tight; the timbers on the down-stream side of the crest were spaced 1 in. apart. A short section of the dam about 9 ft. in length was in 1900 built inside the lock cofferdam up to the level of the apron. No further work on this dam was done until August, 1902, when work was recommenced by excavating with a dipper dredge. The dam was built in three separate sections, which were partially completed a short distance up-stream, the bottoms being built to suit careful soundings pre-

vously taken, and then towed to position and the building continued. Only every other pen was filled with stone until the last section was in place and weighted. Triple-lap sheet piles, 9 by 12 ins., were driven to rock on the upper side of the dam for 110 ft. out from the abutment where the dam rested on gravel; the remaining portion of the dam, which is on rock, was merely sheeted with double-lap 1½-in. plank. The lower side of the dam for 120 ft. from the abutment was also sheet piled for the purpose of holding the gravel. The dam was backfilled to within 4 ft. of the eave for about 20 ft. up-stream, partly with gumbo and partly with gravel. Below that portion of the dam on gravel a brush mattress covered with 2 ft. of stone was laid.

The cost of this dam was as follows:

EXCAVATION.

Materials.	
Fuel and oil.....	\$ 96
Labor.	
181 2/8 days.....	267
Total	\$463

FRAMING AND PLACING TIMBERS.

Materials.	Unit cost.	Total.	Per M. ft.
Oak, 132.8 M. ft. B. M.....	\$19.81	\$2,632	\$ 5.07
Pine, 387.3 M. ft. B. M.....	13.71	5,320	10.23
Iron, 25,297 lbs.....	.025	655	1.25
Hauling lumber, 147.4 M. ft. B. M....	1.18	173	.33
Fuel, oil, etc.....		173	.33
Boat spikes, 12 kegs.....	8.65	104	.20

SUMMARY OF DAM No. 1.

	Total.	Unit cost.
Excavation	\$ 483
Framing and placing timber, 520.3 M. ft...	13,668	\$26.27
Sheet piles, 25.2 M. ft.....	1,088	43.02
Filling, 7,984 cu. yds.....	9,439	1.18
Puddling, 8,640 cu. yds.....	2,587	.299
Repuddling (1904), 4,550 cu. yds.....	1,529	.336
Protecting apron and end of dam after flanking of abutment (1903).....	1,212
Changing shape of old dam from step to slope (324 lin. ft.).....	6,177	19.06

The cost of Dam No. 2 is given in equal detail in *Engineering-Contracting*, but it will suffice here to say that each man framed and placed 250 ft. B. M. per day, at a cost of \$7.62 per M, there being 600 M all told.

Foundation Crib.—The crib was T shaped in plan, following the general outline of the dam abutment. The length of the river face was 136 ft., its width was 12 ft. at the up-stream end and 16 ft. at the down-stream end, and 24 ft. near the middle for a distance of 37 ft., beginning 46 ft. from the up-stream end. The portion of the crib underlying the stem of the abutment was 20 ft. wide and 60 ft. long from face to end; it entered the bank 36 ft. The crib, which was constructed of 10 by 10-in. squared timbers, was built afloat and with interior pens varying in size from 5 to 10 ft. to 10 by 12 ft. After having been settled in place it was filled with "one man" stone up to 2 ft. below extreme low water (6 ft. below water level at the time), the filling averaging 11 ft. in depth. Before this filling began, however, the distributing boxes for the grout were placed. These consisted of open-ended square boxes (8 by 8

ins. inside) of 2-in. plank perforated with 1½-in. holes spaced zigzag 1 ft. apart down the sides. They were long enough to reach just above a loosely laid floor on the top timbers and were set about 10 ft. apart throughout the crib. The cost of these boxes is given under grouting. After the grout boxes had been placed and the crib filled with rubble 9-in. triple-lap sheet piling was driven with a steam hammer along the outside of the crib from a point opposite the downstream edge of the apron to the up-stream end of the crib, and thence around the end and along the up-stream face of the stem. The other faces of the crib were sheeted with double-lap 1-in. plank driven by hand mauls. The sheet piling was also for the purpose of preventing leakage under the abutments, otherwise the double sheeting of 1-in. plank would have answered throughout. The sheet piling and plank sheeting were well spiked to the top timbers of the crib. Gravel and earth were then deposited around the crib up to the water level for a double purpose: First, to prevent the grout from forcing its way through the sheeting, and second to serve as a cofferdam when the time came to pump out the crib.

The cost of this foundation crib was as follows:

FOUNDATION CRIB.

Material.	Total.	Per M. ft. of crib.
Lumber, pine, 65.3 M. ft. B. M. at \$11.36....	\$ 742	\$11.36
Lumber, hauled, 50.3 M. ft. B. M. at \$1.25....	63	.96
Iron, 5,123 lbs., at \$0.023.....	119	1.82
Miscellaneous materials.....	100	1.53
Total cost of materials.....	\$1,024	\$15.67
Labor.		
Framing and placing, 65.3 ft., 981 2/8 days..	\$1,859	\$28.47
Grand total.....	\$2,834	\$44.14

The average work done per man per day was 66.6 ft. B. M. of timber framed and placed.

SHEET PILES AND SHEETING.

Materials.	Total.	Per M. ft. in place.
Lumber, oak, 18.8 M. ft. B. M., at \$15.79....	\$ 299	\$10.40
Lumber, pine, 9.9 M. ft. B. M. at \$13.99....	139	4.82
Lumber, hauled, 9.9 M. ft. B. M., at \$1.25....	12	.86
Spikes, 800 lbs., at \$0.031.....	25	.42
Total cost of materials.....	\$ 475	\$16.50
Labor.		
Driving, 28.7 M. ft., 334 days	\$ 730	\$25.43
Grand total.....	\$1,205	\$41.92

FILLING WITH RIPRAP.

Material.	Total.	Per cu. yd.
Riprap, 876 cu. yds., at \$0.74.....	\$ 648	\$ 0.74
Labor.		
Filling and placing, 118 days.....	\$ 235	\$.27
Inspection of riprap, 10 days.....	18	.02
Grand total, 876 cu. yds. riprap.....	\$ 901	\$ 1.03

The average work done per man per day was 6.84 cu. yds. of rip-rap placed.

Cost of a Cofferdam and Aqueduct.—In 1840, on the Erie Canal, when skilled laborers were paid \$1 per day of 11 hrs. worked (and stonecutters received \$2.25 a day—carpenters' wages not stated), a cofferdam (built by contract) containing 157,500 ft. B. M. of timber and plank was built with 830 days of skilled labor and a few carpenters. This is equivalent to 190 ft. B. M. per man per day. If wages had been \$2 per day, this would have meant a cost of \$10.50 per M.

In building (by contract) an aqueduct trunk or flume, supported by masonry arches, the timber gang consisted of 2 carpenters to every 1 skilled laborer. There were put in 892,400 ft. B. M. of timber, of which 260,300 ft. B. M. were framed. This required 3,153 days of carpenters and laborers. The average day's work for each man was:

	Ft. B. M.
Framing	648
Putting in the work.....	324

If wages had averaged \$2.50 per day (2 carpenters to 1 laborer) this would have meant a cost of \$4 per M for framing and \$3 per M for putting in the work, or a total of \$12.

Cost of Four Caissons.—Mr. B. L. Crosby gives the following on the construction of four piers for a double-track bridge across the Missouri River, for the St. Louis extension of the St. L., K. & N. W. R. R. The foundation work was done by company labor. The masonry piers were founded on pneumatic caissons, each 30 x 70 ft. outside measure, excepting one which was 24 x 60 ft. The caissons were 16 ft. high, including the iron cutting edge, and surmounted with a timber cribwork. This cribwork was 24 ft., 45 ft., 53 ft. and 64 ft. high, respectively, on the four piers. All the caissons, except one, were built on launching ways on the north side of the river, just above the bridge line. These launching ways were constructed by driving piles, which were capped by 12 x 12-in. timbers running up and down stream, and then the 12 x 12-in. way timbers were drift-bolted to the caps. The ways had a slope of 3 ins. to the foot toward the river, and extended far enough out to allow the caisson to float before being clear of the timbers. Piles were cut off under water with a circular saw, and the drift-bolts, which had been started into the caps before they were sunk, were driven by a ramrod working through a gas-pipe over the drift-bolt. To remove a sand-bar at the site of one of the piers, a steamboat was anchored to piles over the pier site, and by the revolution of its paddle wheels washed out a hole 7 to 10 ft. deep. Barges were placed each side of the caisson, and heavy timbers bolted across the caisson, and extending out over the barges. The caisson was towed to its site, and when it struck a sand-bar, air was pumped into the caisson to raise it so as to clear the bar. In sinking the caisson a Morrison sand-pump and a Morrison clay-hoist were used. The greatest depth reached below low water was 101 ft., and laborers in the caisson received \$2.50 a day of 2 or 3 hrs. (working 1-hr. shifts) at this

great depth. The pneumatic plant used in sinking consisted of two No. 4 Clayton duplex compressors, having steam and air cylinders, each 14-in., with a 15-in. stroke; a Worthington duplex pump, $18\frac{1}{2} \times 10\frac{1}{2} \times 10$ ins., and a small dynamo and engine. This plant was set up on the steamboat whose boilers furnished the power. There was also a duplicate plant, which was used part of the time, supported on a pile platform. There were several hoisting engines, a pile driver boat provided with a derrick for handling timbers in building up the cribwork on the caissons. The concrete used to fill the cribwork was 1:2:4 Louisville cement, and 1:3:6 Portland cement.

In these four caissons and cribs there were 1,609 M of yellow pine. The cost of framing and building the caissons was \$21.93 per M. This includes cost of launching ways, and of material and labor of all kinds; except the cost of the timber itself. It also includes all handling and towing. Carpenters were paid \$2.50 and laborers \$1.75 per day.

There were placed in these caissons 13,335 cu. yds. of concrete requiring 16,035 bbls. of Louisville cement and 4,759 bbls. of Port-

Fig. 4. —A Small Scow.

land cement. The cost of this concrete (broken stone was used) was \$5.36 per cu. yd.

The average cost of caisson and concrete filling, including cutting edges, shafting, etc., was 34.2 cts. per cu. ft.; the average cost of sinking 9 17 cts. per cu. ft., this average being materially increased due to some rock excavation on one pier where the average cost of caisson sinking was 12.33 cts. per cu. ft. The average cost of caissons was \$178 per ft. sunk, ranging from \$116 per ft. on one to \$259 per ft. on the one where rock was encountered. Work on the first caisson was begun July 30, 1892, and it was launched Aug. 20. It reached bed rock Jan. 2, 1893, at a depth of 89 ft. below low water. The first engine passed over the completed bridge Dec. 27, 1893.

For much more detailed costs of caisson work see data in the section on Bridges.

Cost of Two Small Scows.—For use in river work, two small scows were built as shown in Fig. 4. Each scow was 2 ft. deep, 6 ft. wide, and 32 ft. long. It consisted of four parallel frames made by spiking 2 x 6-in. hemlock to form rough trusses. These frames were 2 ft. apart, and to them rough hemlock sheathing plank was spiked,

making deck bottom, sides and ends of a closed box. All the joints, except the deck, were calked with oakum and tarred. Thus very cheap and watertight scows were made. They were strong enough to be used for a floating pile driver, by bolting the two scows side by side; but they were not quite large enough for this purpose and the leaders of the pile driver had to held with guy ropes, which was a great nuisance. Nevertheless, this rough and light construction proved good enough in every other respect for river work where no logs or other heavy objects could batter the scows. The cost of these two scows was as follows:

3 M. rough hemlock, at \$11.....	\$33.00
15 lbs. oakum, and necessary pitch.....	1.50
1 keg nails.....	2.00
12 days' labor, at \$2.....	24.00
Total for two scows.....	\$60.50

This is equivalent to \$30 each for the scows. One carpenter, at \$2.50, assisted by one laborer, at \$1.50, did the work, which cost \$8 per M. During the winter the scows were hauled out of the water, and next spring re-calked with 8 lbs. of oakum, requiring the labor of one man for 14 hrs. Each scow was readily loaded on a wagon for transportation.

Cost of a Semi-Circular Flume.—Mr. William H. Hall is authority for the following relating to the work on the Santa Ana Canal of the Bear Valley Irrigation Co., in San Bernardino County, California, in 1894. Wooden stave pipe and a semi-circular stave flume, invented by Mr. Hall, were largely used, and cost data are given. The flume is 5½ ft. in diameter, semi-circular, made of dressed red-wood staves 1½ ins. thick held by binding rods or hoops (2 ft. 8 ins. apart) passing through 4 x 4-in. wooden cross-yokes. The flume rests on sills or bolsters (10 ft. apart) cut to fit its curved bottom, and these sills are supported on concrete blocks or on wooden trestles according to the locality. A gang of 10 laborers and 5 carpenters and a foreman built the flume. Not a nail was used in its construction. Wages were high, being \$2 a day for laborers, \$3 a day for carpenters, and \$4 a day for team and driver. The cost of erecting the flume, exclusive of trestle work, was \$5.75 per M, but this does not include shop work, delivery and calking. The cost of delivering the lumber in wagons was \$2.50 per M and subdelivering it on dollies was \$2.50 per M more, as the work was in a rough country; hauling costing 37½ cts. per ton mile by contract. The cost of making the sills, and yokes, and dipping all the lumber in coal tar, and calking after erection, came to \$3.25 per M, including all timber in the flume, exclusive of trestles. Hence the total labor cost, including delivery and subdelivery, was \$14 per M. The lumber was bought for \$28 per M.

The cost of framing and erecting timber trestles to support this flume was \$13 per M, the rough pine itself costing \$19 per M; the cost of delivering was presumably \$5 per M. The work was half over before the men became trained to their work, and at no time were they very active or efficient.

The total amount of dressed redwood for the flume staves was 312 M, which required 214,000 lbs. of wrought and cast iron for bands, bolts, etc., or about 700 lbs. per 1,000 ft. B. M. This iron cost 5½ cts. per lb. At these high prices the cost of the finished flume was about \$5 per lin. ft., of which \$2.50 was for the flume alone and \$2.50 for the trestle supporting it.

Cost of a Wood Flume, Klamath Irrigation Project.*—The flume is 4,303 ft. long, and has an inside width of 11 ft. and inside height of 5½ ft.; it rests on concrete piers with rubble-stone foundations, and is built of red fir lumber. Of Class 1 lumber, for the framework of the flume, 442,000 ft. B. M. were purchased at \$15.50 per thousand, delivered. Measurement after construction, however, showed only 438,000 ft. B. M. in place, and thus indicated a waste of 4,000 ft. B. M., or a little less than 1%. Of Class 2 lumber, for lining the flume, 50,000 ft. B. M. were purchased at \$30.50 per thousand, delivered, and 227,000 ft. B. M. at \$19 per thousand, making a total purchase of 287,000 ft. B. M. Measurement after construction showed 284,200 ft. B. M. in place, thus indicating a waste of 2,800 ft. B. M., or about 1%.

The concrete piers and stone foundations were built by force account. The piers, 1,091 in number, are 18 ins. high, 24 ins. square at the base, and 12 ins. square at the top, and rest on rubble foundations 3 ft. square.

The total costs on which the tabulated unit costs are based are \$21,000 for the flume proper and \$6,995.88 for the foundations; in addition, however, there were costs, not distributed in the unit costs, of \$174.96 for a spillway and \$347.54 for miscellaneous expenditures, making a total cost for the whole structure of \$28,518.38, or \$6.64 per lin. ft. of flume.

Cost of Lock Gates.†—Maj. Graham D. Fitch gives the following: The gates for the lock described on page 570 are of the standard form, namely, mitring gates of the girder type with straight back and front. They are horizontally framed and without quoin or miter posts, the main timbers extending from edge to edge of the

**Engineering-Contracting*, May 26, 1909.

†*Engineering-Contracting*, May 6, 1908, p. 281.

gate and the ends, which are built up solid with filling blocks, being shaped to fit the hollow quoin and miter, respectively, thus avoiding the weakness of beams jointed into vertical heel and toe posts. The rise was taken as $1/8$ of the span, which is equivalent to a miter angle of 18 degrees 28 minutes.

The gates are of white oak, 20 ins. thick throughout, each arm consisting of a built-up beam composed of two 16 by 10-in. timbers bolted together with 1-in. bolts and extending in one length from toe to heel. The tops of the gates are flush with the tops of the lock walls, so that the lock can be used until the walls are submerged. The lower gates, which are 20 ft. 5 ins. in height, are built solid for 16 ft. from the bottom. For the upper gates these figures become 16 ft. 5 ins. and 20 ins., respectively. By making the lower portion of a gate solid, the gate may be made thinner, thus reducing under pressure. The upper portions of the gates are paneled; the arms are all made of the same scantling as below, but are spaced inversely as the maximum loads; the arms are separated by five blocks (including the two at the heel and toe), and the intervals are closed with a sheathing of 2-in. oak plank made watertight by calking. The beams are held together by seven pairs of long $1\frac{1}{4}$ -in. bolts running vertically through the center lines of the main timbers as well as through the filling blocks in the upper part of the gate. The weight of the gate is taken up by two diagonal tie straps of $3\frac{1}{2}$ by $\frac{3}{4}$ -in. wrought-iron eyebars provided with turnbuckles; one end of each eyobar passes over a pin in the journal strap and the other over a similar pin held in place near the lower end of the toe by a stirrup strap and a nose strap. The bottom beam is fitted at the quoin with a cast-iron heel piece which rests on a forged steel pivot shrunk into a cast-iron pivot plate having sufficient bearing. This bedplate is bolted to the concrete. The top gudgeon is a 3-in. steel pin supported at both ends by journal castings, between which the collar works. In order that the leaf may, in opening and closing, swing clear of the quoin without friction, the rotation axis of the pivot and gudgeon is on the up-stream side of the center of figure of the hollow quoin when the leaf is closed, the eccentricity being $1\frac{1}{4}$ ins. The up-stream half of the toe is rounded off so that the surface of contact when the gates are mitered shall fall upon the down-stream timbers of the built-up beams. Thus the compression due to the end reactions is thrown on the down-stream timbers where it will relieve the tension from the direct loading, and is removed entirely from the up-stream timbers to avoid increasing the compression from the direct loading.

The anchorage for the gates consists of four wrought-iron bars with cast-iron washers or anchor plates embedded in the concrete and connected in pairs at their exposed ends to two heavy castings. The anchorage connections fit in a recess below the coping and are covered with a cast-iron plate.

The method of building and placing the lock gates was as follows:

A small hand-power derrick was erected on a level spot so as to command the ways, which were built of heavy timbers laid perfectly level about $2\frac{1}{2}$ ft. from the ground and close enough together to support without deflection the weight of an entire gate. On each side of the derrick were placed two sets of ways, between which ran a track for carrying the timbers. The gate timbers were delivered as needed to the derrick and placed on the ways, the built-up beams framed and bolted, and the heel and toe worked to pattern. The arms and blocks were then juxtaposed in position so as to get the alignment of the long bolts and then separated for the holes to be bored. This was a tedious procedure, as no matter how carefully the measurements for the holes were made it was found impossible to bore all of them in the different pieces so as to avoid slight errors of alignment; hence burning the holes out with long rods of hot iron had to be resorted to. The gate was then assembled, the bolts inserted and tightened, the irons fitted on, the heel and toe worked to pattern, and each arm and block numbered to avoid any displacement later. The gates were then taken apart and transported to the lock pit to be erected piece by piece, for which a land derrick was used. As each beam was put into position its top was given a heavy coat of white lead, and the position of its bolt holes tested by thrusting down an iron rod. After the gate had been thus built up to the required height, the long perpendicular bolts were raised by the derrick and put into place, the various irons fitted, the anchor bars and tie straps tightened, and the gate swung. The gates were then given two coats of red lead.

The gates are operated by hand power. The maneuvering gear consists of a spar, to each end of which is fastened one end of a chain; the bight of this chain is led through a chain guide consisting of two sheaves to a chain capstan worked by a crank. The gate is opened or closed according as the chain is pulled in one direction or the other.

As wooden lock gates subject to varying lifts, unless made too heavy at low water, are too buoyant at high water, it is necessary at the approach of floods to ballast them, which was done by filling the panels with large stones.

The miter sills, which provide an elastic cushion for the bottom of the gates, consist of 12 by 12-in. timbers well bolted to the miter wall, as they may sometimes be subjected to a lifting pressure from the gates, and when once started the upward water pressure is of course added. The miter sills are 2 ins. higher than the miter walls so as to act as a guard for the masonry. The miter sills are 1 ft. below normal 4 ft. depth, so as to permit the pool level to be reduced without affecting navigation. The sills, like the gates, are of white oak and were set when the concrete was placed in the miter walls. The gates do not, when shut, extend over the sill, as is sometimes the case, for a difficult joint then becomes necessary. In this instance the gates lap the sill by 5 ins., the under pressure being counterbalanced by the weight of the gates.

The cost of the gates and sills was as follows:

Material:	Unit cost.	Total.
Lumber, oak, 35.7 M ft. B. M.....	\$41.87	\$1,477
Iron, wrought, 342 lbs.....	.05	17

The total labor time in days for framing was 684 $\frac{4}{8}$ and the work done per man per day was 53.1 ft.; the total labor time for setting the four gates was 149 $\frac{1}{2}$ days.

Cost of a Railway Box Car.—Mr. E. C. Spaulding is authority for the following data on small box cars built in 1882. The car was probably designed to carry about 30,000 lbs., for its own weight must have been about 23,000 lbs.

Material in Body:	
4,000 ft. B. M., at \$20.....	\$ 80.00
700 lbs. wrought iron, at \$0.05.....	35.00

$\frac{1}{4}$ day painter, at \$2.00.....	0.50

Total
Grand total

\$ 6.13
\$506.61

It will be noted that the cost of the labor on the box of the car was \$45 for 4,000 ft. B. M., or \$11.25 per M. The labor cost on the 490 ft. B. M. in the trucks was practically the same rate.

By reference to data in the section on Buildings, it will be found that the labor costs of frame buildings is about the same as above given for this box car.

Cost of Making Bodies for Dump Cars.—Some bodies for bottom-dumping cars were made to be mounted on ordinary hand-car trucks, and were used in filling a trestle. The car bodies were made hopper shape, the sides being 4 ft. apart; the ends were $6\frac{1}{2}$ ft. apart at the top and sloping toward the center until they were 4 ft. apart at the bottom. The height of the body was 20 ins., thus giving a struck-measure capacity of 38 cu. ft. Two doors, forming the bottom of the car, were hinged to the two ends of the car body with three 14-in. strap hinges to each door. These doors were each 18 ins. wide and 4 ft. long, and were closed by means of hoisting chains ($\frac{1}{2}$ -in. iron) passing around a $2\frac{1}{2}$ -in. gas pipe winch which spanned the car from side to side. This $2\frac{1}{2}$ -in. gas pipe was stiffened by a $2\frac{1}{4}$ -in. pipe slipped inside. It required 150 ft. B. M. of plank to make each car, and a carpenter (35 cts. per hr.) with a helper (15 cts. per hr.) averaged one car in 7 hrs., which is at the rate of \$10 per M.

Cost of Making Tool Boxes.—A carpenter made two tool boxes of 1-in. matched pine boards in 16 hrs. Each box contained 130 ft. B. M., so that the labor cost was a little less than \$10 per M, wages being 25 cts. per hr.

Cost of Plank Roads.—Very often the contractor would be enabled to haul much larger loads in wagons if he were to build plank roads up certain short steep ascents, or up out of the pit. The planks need not be spiked to the stringers. Plank for such roads should be 8 ft. long and 8 ins. thick. Contrary to general opinion cedar makes an excellent plank road, for its surface soon becomes a thin mat of wood fibers and dirt that protect the body of the plank. Either three lines of 4 x 6-in. or two lines of 3 x 12-in. cedar stringers should be bedded in the ground and the plank laid upon them without spiking.

In the State of Washington I found the cost of building the very best of these plank roads to be as follows: Three skilled laborers bedding three lines of 4 x 6-in. stringers in clay, laying and spiking 8-in. plank, averaged 15,000 ft. B. M. per 16-hr. day. At \$2.50 per day per man, the cost would be 0.50 per M. In sand these men averaged 18,000 ft. B. M. per day. They were hustling, as they received 50 cts. per 1,000 ft. B. M. for laying this road, plank being delivered alongside.

Over such a road a team can pull as much as on the very best asphalt pavement. The "trick" about building a good plank road is to bed the stringers, not leaving them on top of the ground. The road then is firm and great loads can be hauled over it, so long as it is kept in good condition.

Since in temporary roads the spiking may be omitted, and as a

matter of fact it should be omitted even on permanent roads, we see that the plank may be used over and over again for different jobs; but if the road is worth laying at all it is worth laying well in the first place.

Plank road work lends itself admirably to payment by the piece rate or by the bonus system.

Piles.—Piles are sold by lumber dealers at 5 to 15 cents per lin. ft. of pile for all ordinary lengths, but very long piles bring high prices per lin. ft. Specifications usually provide a contract price per lin. ft. for "piles delivered" on the work ready to drive; and another price per lin. ft. for "piles driven." The length of the "pile driven" is the full length of the pile left in the work after cutting off the broomed head, although occasionally it is specified to be the length of the pile underground. Hence care should be taken to make clear what is meant by the expressed "per foot of pile driven."

The actual cost of driving a pile should be recorded in dollars and cents per pile, as well as in cents per lin. ft. of pile driven; for costs vary less per pile than per lin. ft. This is evident when we consider that where the driving is easy a very long pile is driven in no longer time than is required for a short pile where driving is hard.

I prefer to specify payment for "piles delivered" by the lineal foot, and for "piles driven," by the pile.

Pile Drivers.—There are three types of pile drivers: (1) Free fall; (2) friction-clutch; and (3) steam-hammer. In the free-fall driver, the hammer is detached from the hoisting rope and allowed to fall freely upon the pile. In the friction-clutch driver, the hammer remains always attached to the hoisting rope, and, by means of a friction clutch on the hoisting engine, the drum is thrown into gear or out of gear at will. When the clutch is thrown out of gear, the hammer falls, dragging the hoisting rope after it. The Nasmyth steam-hammer is raised by steam acting direct upon a piston attached to the hammer. The hammer is raised about $3\frac{1}{2}$ ft., and allowed to fall by gravity.

A steam-hammer strikes about 40 blows per minute. A friction-clutch hammer strikes about 18 blows per minute when the hammer falls 12 ft.; and 25 blows per minute when the hammer falls only 6 ft. A free-fall hammer strikes about 7 blows per minute when the fall is 20 ft. and a hoisting engine is used.

The free-fall hammer is much used where horses do the hoisting instead of an engine. In either case a lug on top of the hammer is gripped by a pair of "tongs," which are tripped at the desired height, allowing the hammer to fall. The "tongs" descend slowly by gravity helped perhaps by the man who has tripped them, and they automatically grip the hammer again. The "tongs" are also called "scissors" or "nippera."

The two upright timbers that guide the hammer are called "leads," or "leaders," or "gins," or "ways." A common weight of hammer for a free-fall or a friction-clutch machine is 2,000 to 3,000 lbs.

An "overhang driver" is a driver provided with leads that project

8 to 20 ft. beyond the base of support of the driver. The horizontal beams that support the leads of an overhang driver are trussed; and the weight of the engine on the rear of the trussed beams counterbalances the weight of the leads and the hammer on the front. A cheap driver of this type can readily be made for driving the bents of a pile trestle across a river, or other body of water, where a scow is not available for mounting the driver upon. The author has built such a driver with a 20-ft. overhang for driving falsework pile bents across a river.

A "railway pile driver" is a heavy driver of the "overhang" type, mounted on a railway flat car. Sometimes these drivers are made self-propelling; but frequently a locomotive is used in handling the driver. The leads are so made that they can be lowered when passing under overhead bridges, etc. In working with an overhang driver, there is always considerable delay, for as soon as the 3 or 4 piles for a bent have been driven, they must be sawed off and capped with a 12 x 12-in. stick drift-bolted to the piles, before the beams or stringers can be laid to support the driver when it moves forward.

A "scow driver" will drive more piles per day than a "railway driver," because this delay in sawing off and capping each bent does not occur. Moreover, the piles are floated alongside the driver ready for instant use. The scow itself is quickly shifted by means of ropes from suitable anchorages to the winch-heads of the engine.

Excepting on railway work, land drivers (as distinguished from scow drivers) are seldom mounted on wheels running on a track; but are usually supported on rollers running on plank or timber runways laid down in advance of the driver. If the ground is very irregular, it must be either graded, or the timber runways for the driver must be supported by cribbing or blocking so as to give a level runway for the driver. The building of such a runway often retards the work of land-driving.

Excepting where the driving is exceedingly hard, the hammer is actually at work but a small fraction of the day at best. The contractor should, therefore, exercise his wits to reduce the lost time.

There are no very reliable data as to the relative effectiveness of the blows of steam-hammer drivers and friction-clutch drivers, but the following data by Mr. N. E. Weydert may prove of value:

In driving piles in Chicago, piles 54 ft. long were driven 52 ft., of which 27 ft. were in soft clay, and 25 ft. in tough clay. Each pile averaged 12 ins. in diameter. Using a Nasmyth steam hammer, striking 54 blows per minute, with a weight of 4,500 lbs. falling 3½ ft., it required 48 to 64 blows to drive the last foot when a follower 20 ft. long was used on top of the pile; but, without a follower, it is estimated it would have taken only 24 to 32 blows to drive the last foot. After a pile had stood 24 hrs. it required 300 to 600 blows of the hammer on the follower to drive it 1 ft.

In the same soil, using a 3,000-lb. drop hammer falling 30 ft., and striking a follower 20 ft. long, it required 16 blows to drive the

last foot; but with the same hammer falling 15 ft., it required 33 to 36 blows on the follower to drive the pile the last foot.

The piles were tested with a load of 50 tons each for two weeks and showed no settlement.

The Steam Hammer vs. the Drop Hammer.—Some 50 years ago, when the Nasmyth steam hammer came into prominence as a pile driver, it was predicted by engineers who had seen it that the days of the rope hoisted hammer were numbered. Nor is it uncommon to read similar predictions even to this day. That the steam hammer weighing two tons and striking 60 blows a minute is a very effective machine no one can deny, but what appears to have been overlooked by many engineers is the fact that in nearly all driving of piles on land, a very small fraction of the working day of a pile-driving gang is spent in actual driving. This is particularly the case in building pile trestles with a railroad pile driver.

Records that I have kept show very clearly how little time is ordinarily spent in pile driving on trestle work, using the ordinary railroad pile driver with a friction-clutch engine. Each trestle bent consisted of four piles driven about 10 ft. into firm, dry earth, and bents were 15 ft. c. to c. It took about 20 blows of a 2,300-lb. hammer falling about 15 ft. to drive each pile, and, once the pile was in the leaders, these 20 blows were delivered in from 1 to 3 minutes, depending upon minor delays in keeping the pile plumb. The piles were not ringed. Hence we may say that in so far as the actual time of driving four piles was concerned, only 8 minutes were thus consumed per bent at the most. About 4 or 5 minutes were required to get each pile into the leaders, thus consuming some 20 minutes per bent.

Tabulating the time consumed in performing each detail we have:

	Minutes.
(1) Getting 4 piles into leaders.....	20
(2) Driving 4 piles.....	8
(3) Straightening and bracing the piles.....	27
(4) Levelling and nailing guide strips for sawing off..	10
(5) Sawing off 4 piles.....	12
(6) Putting on cap and drift bolting it.....	12
(7) Pulling 3 stringers forward from last bent.....	11
(8) Putting in 2 more stringers that overhang.....	20
(9) Putting in 1 tie and spiking rail.....	4
Total time on one bent.....	126

Item (4) was unnecessarily long, due to the hair-splitting methods of the Y-level man, who was giving the cut-off. Even after the cleats to guide the saws were nailed on, he had them lowered $\frac{1}{8}$ -in.

Items (3) and (5) may frequently be reduced very materially, and always would be on contract work, but on work done for a railroad company, as this was, the end of the 10-hr. day will find only 4 to 6 bents built under the conditions here given. If, however, we assume a bent of four piles built in 100 minutes, we see that only 8 minutes of that time will be consumed in actual driving. In other words, only three-quarters of an hour out of the 10 hrs. is spent in hammering the pile. This will doubtless be surprising to many engineers, and particularly to those who have been impressed

by the speed of the Nasmyth steam hammers. Under a hustling, wide-awake contractor, the writer has seen 10 bents driven and completed in a day with a friction-clutch driver; but even under such conditions the hammer was actually at work driving less than two hours.

It seems quite clear from the foregoing discussion, that maintenance-of-way engineers should look not to improvements in the form of hammer mechanism, but rather to improvements in the mechanism and methods of handling the piles, caps, stringers, etc. Very much can be accomplished in this respect by having a well-organized force with a clear-headed foreman at its head. In the example just cited the item of straightening piles was exceedingly expensive in time, in that it consumed nearly half an hour. This was largely due to the fact that the foreman did not appreciate the importance of sawing the pile heads square. He simply put the piles into the leaders with the heads rough sawed as they came from the forest. In one case the pile had a large prong of splintered wood projecting above the partly sawed head. Haste never makes more waste than in neglecting to square the pile heads, and guide the pile properly while driving it.

In this particular instance, since the driving was across dry land, the foreman should have secured a team with which to "snake" piles and timbers up alongside of or directly in front of the driver. Then the pile rope or "runner" could have been quickly hooked on to a chain already fastened around the pile or timber to be moved, with a saving of 50% in the time spent in getting material to place. It does not pay to make a team out of a pile driver and a gang of men.

Instead of spending 13 minutes getting a cap to place and drift-bolting it, not more than 4 or 7 minutes need have been so consumed. Two men can cross-cut a pile in 4 or 5 minutes, hence with eight men on four saws, item (5) can be reduced at least one-half. Running around looking for saws, mauls, drift bolts, etc., is one of the greatest causes of delay. For this reason there should be a man whose duty it is to bring tools and put them away immediately after they have served their purpose. The two leader men on the driver might well attend to the tools.

We see, by this method of timing, why the Nasmyth steam hammer has failed to displace the friction-clutch hammer on trestle work, and we see that if any improvement is desirable in driver design it is not in the hammer mechanism, but rather in the means of mechanically handling the timbers. Finally we see that organization of the force is quite as essential as improvement in mechanism, while it possesses the decided advantage of costing nothing except what may be paid for a better quality of brain work.

From this discussion it should not be inferred that the steam hammer has no field of usefulness, for it has. Its field, however, is in scow or land driving, where a great number of foundation piles are to be driven close together, and especially where a great number of blows must be struck to secure the desired pile penetration.

Cost of Making Piles.—Two men can cut down and trim 17 oak piles per day, each pile being 20 ft. long. Where the men are paid \$1.75 per 10 hrs., the labor cost of making the piles is practically 1 ct. per lin. ft. To this must be added the cost of hauling and freight to the place where the piles are to be driven.

For weight of piles, see the fore part of this section.

Life of Pile Driver Rope.—Mr. George J. Bishop kept some records of pile driving on the C., R. I. & P. Ry. in 1897, to determine the life of manilla rope. The drum of the friction pile driver engine was 14 ins. diam., also the sheave at the top of the leads, and the sheave at the front of the pile driver was 20 ins. The hammer weighed 3,000 lbs. The rope was of three different makes, all 1½ ins. diam. Common manilla 8-ply rope made the best showing. The length of rope was 125 ft. and its weight ranged from 74 to 95 lbs., averaging 85 lbs., or nearly 0.7 lb. per ft. The price of the rope was 6½ cts. per lb. or \$5.53 per average rope. Ten ropes were used up in driving 1,335 piles to an average penetration of 30 ft. Hence each rope averaged 133 piles, or a cost of 4 cts. per pile for rope. However, 5 of the ropes averaged only 101 piles each, and 5 averaged 186 piles each.

Cost of Driving Piles With a Horse Driver.—This work consisted in driving 219 piles, 3 ft. centers, to form the protecting toe of a slope-wall. The hammer weighed 2,000 lbs., and was raised with block and tackle by horses. Two teams were used alternately. As soon as the hammer was tripped, two men pulled back the hammer rope hand over hand, and hooked it on to the second team while the other team was returning. In this way the blows were delivered almost twice as rapidly as when one team only is used. The driver was supported on wooden rollers sheathed with iron and provided with sockets into which bars could be inserted for turning the rollers. The rollers rested on planks laid on the ground which was comparatively level and required no staying or grading to secure a level runway for the driver. Pine piles, 15 ft. long, were driven in a stiff clay to a depth of 13 ft.

The average number of piles driven per 10-hr. day was 21, but the best day's record was 30. The cost was as follows per day:

5 laborers, at \$1.50.....	\$ 7.50
1 foreman, who worked.....	2.50
2 teams and drivers, at \$3.00.....	6.00
Rent of driver.....	2.00

Total, for 21 piles, at 35 cts.....\$12.00

The piles cost 10 cts. per ft. delivered; and the contract price was 24 cts. per ft. delivered and driven.

On another contract under my direction, where piles were spaced 10 ft. centers and driven 12 ft. into gravel along the sloping bank of a river, it was necessary to do more or less grading and blocking up to secure a level runway for the pile driver. Four men and a pair of horses averaged only 6 piles per 10-hr. day, making the cost about \$1.60 per pile for the labor of driving. This gang was too small, and worked deliberately.

Cost of Driving Foundation Piles for a Building.—On this work, which consisted in driving long piles for the foundation of a building in Jersey City, a pile driver mounted on rollers was used. The leaders were 60 ft. long, and provided with two head sheaves, one for the hammer rope and one for the rope used in hauling and raising the piles. The hammer weighed 2,100 lbs.; and the engine was a double-drum friction-clutch. The piles were of spruce 50 ft. long, and were driven their full length in soft clay. For the first 10 ft. the piles were driven without ringing. When the pile head reached the bottom of the leaders, a short wooden follower was used for the last 10 to 25 blows. The pile ring was then pulled off the pile by a short iron peavy lifted by the pile rope. The piles were stacked up in the street about 100 ft. away from the driver, and were "snaked over," when wanted; the pile rope being used for the purpose. For the first few blows the hammer had a fall of only 5 ft., and about 25 blows per min. were delivered. But after that the fall of the hammer was 12 ft., and about 18 blows per min. were delivered. It required about 110 blows to drive a pile its full 50 ft. The time required to drive one pile was as follows:

	Minutes.
Hooking on dragging pile to driver.....	5
Hoisting pile and getting it in place.....	2
Hammering pile	8
Putting ring on pile	1
Placing follower on pile.....	$\frac{1}{2}$
Removing follower from pile.....	1
Removing ring from pile.....	$\frac{1}{2}$
Shifting pile driver 2 ft.....	1
Total time per pile.....	17

It will be observed that the hammer was actually engaged in hammering not much more than one-third of the total time. When everything was working smoothly 35 piles were driven in 10 hrs., but the output frequently fell below 30 piles in a day, due to sundry slight delays and accidents.

The cost of operating the driver was as follows:

1 engineman	\$ 3.00
1 man up the ladder.....	1.50
4 men handling and guiding pile.....	6.00
1 man sharpening piles.	1.50
1 foreman handling pile rope, etc.....	4.00
$\frac{1}{2}$ ton coal, at \$6.....	2.00
Total per day for labor and fuel.....	\$18.00
Rent of pile driver.....	3.00
Total, at 60 to 70 cts. per pile.....	\$21.00

This does not include cost of delivering and removing the pile driver.

The Construction and Cost of a Small Pile Driver.*—Frequently a pile trestle must be built, and the number of piles to be driven may not warrant buying, or even hiring, a pile driver of ordinary size.

**Engineering-Contracting*, January, 1906.

In such cases a small driver may be built at a nominal cost, and it will do very effective work where the piles are to be driven to a moderate depth. Such a driver (Fig. 5) was built by the managing editor of this journal some years ago, and a description of it will be given.

The "leads," or "gins," that guided the hammer were made of 4-in. x 6-in. sticks, 30 ft. long. The hammer was of cast iron and weighed only 1,200 lbs. The rope that raised the hammer was 1-in. manilla. One end of this hammer rope was fastened to the "nippers" that clutched the lugs on the hammer. The other end of the

Fig. 5.—Small Pile Driver.

rope passed through a pulley and around a wooden drum 12 ins. in diameter. At one end of this wooden drum was fastened a wooden "bull wheel," 60 ins. in diameter. Another rope was wound around this "bull wheel," and a horse was hitched to the rope. The horse easily raised the hammer to the top of the "leads," where the "nippers" were automatically tripped, allowing the hammer to fall. The reader will note that only one pulley block was used. The use of a drum and "bull wheel" made it unnecessary to get any more blocks, and thus reduced the first cost; but, what is even more important, a "bull wheel" and drum does not consume the power of the horse in friction to any such degree as is the case where pulley blocks are used.

The bill of lumber for the driver is as follows:

Piece.	in.	in.	ft.	Ft. B. M.
2—	4 x	6 x	30 (leads)	120
1—	8 x	6 x	4 (cross-piece)	12
2—	6 x	6 x	16 (base)	96
2—	2 x	4 x	32 (ladder)	43
2—	2 x	4 x	2 (ladder rungs)	24
2—	4 x	4 x	26 (sway braces)	64
1—	2 x	4 x	20 (long front sill)	18
1—	2 x	4 x	14 (short rear sill)	8
1—	12 x	12 x	4 (drum)	48
30—	1 x	12 x	6 (bull wheel)	180
Total				603

About 24 bolts, $\frac{1}{2}$ x 8 ins., were used, and a few pounds of nails. The wooden drum and "bull wheel" required more time to make than all the rest of the driver. The drum was shaped out of a 12-in. x 12-in. stick, but was left square where the "bull wheel" was to be fastened on. At each end of the wooden drum, a wooden axle, 4 ins. in diameter and 6 ins. long, was cut out; and these axles were fitted to wooden bearing blocks, and were well daubed with axle grease. The wooden "bull wheel" was made of five layers of 1 in. by 12 in. planks spiked together; one layer running one way, the next layer in the opposite direction. First, three of these layers were spiked together, and a 5-ft. circle was marked on them. Then with a key-hole saw the 5-ft. wheel was cut out. On each side of this wheel was spiked another layer of plank and sawed to a circle 5 ft. 8 ins. diameter. These two layers formed the rims of the "bull wheel" and kept the "bull rope" from slipping off.

Two carpenters and two laborers built this driver in two days, at a cost of \$18 for labor. The total cost was:

700 ft. B. M., at \$20.....	\$ 14.00
Bolts and nails.....	2.00
Labor	18.00
1,200-lb. pile hammer.....	50.00
1 pair nippers	5.00
1 snatch block	3.00
240 ft. of 1-in. rope.....	10.00
Total	\$102.00

The driver weighed $1\frac{1}{4}$ tons, exclusive of the hammer, and was easily loaded on a wagon.

The cost of driving piles with it is given in the following paragraph.

Cost of Driving Piles for Wagon Road Trestles.—It was necessary to drive piles for a number of wagon road trestles across ravines, which were often separated by several miles. A light pile driver that could readily be moved from place to place was built, as described on page 1000.

Piles were driven in bents of three piles each, bents 20 ft. apart. In fairly hard ground the piles were driven only 5 or 6 ft. deep. Due to the irregularity of the ground, in nearly all cases it was necessary to build a light scaffolding on which to run the driver across each creek. This scaffolding was made of sticks cut from

the forest alongside, and cost nothing except for labor, which is included in the cost of \$1 given below. The young contractor would be apt to overlook this item of scaffolding, but it should always be remembered that a driver of this kind must have a level runway on which to work, and, if the ground is irregular, it must either be graded or scaffolding put up. Usually scaffolding is cheaper than grading.

The crew consisted of 4 men and 1 horse. It would take them about 2 days to move the driver 4 miles over poor roads, and erect a staging upon which to drive a seven-bent trestle. Then they would average 10 piles driven per 10-hr. day. The cost of actual driving was about \$1 per pile, wages being \$10 a day for the crew; to which must be added another \$1 per pile for lost time moving driver from one trestle to the next and building staging. This was the average cost on six trestles, 34 piles being driven.

Cedar piles were largely used for this work, as the driving was light, and as the durability of cedar is greater than other woods. After driving the piles, 2 men would saw off the heads of 18 piles in 3 hrs., at 6 cts. per pile. These piles averaged 20 ft. in length, and with axmen at \$2 a day each, they were cut down and trimmed for 25 cts. a pile, and hauled 3 miles over rough roads for 50 cts. more per pile.

I found it economic to sublet the pile driving to a reliable carpenter who would work with his gang of three men, and earn good wages for himself and crew if paid \$2 for driving each pile, including all moving and building of staging. The work just described was done in this way. Work handled thus generally insures activity on the part of small gangs of men and reduces the charges for superintendence to a very small percentage.

Cost of Driving Piles for Trestle Renewals.*—Mr. G. H. Herrold is author of the following work done on the Chicago Great Western Ry. in Minnesota.

I have compiled the following statement [the complete tabulation of each day's work is given in *Engineering-Contracting*, but not reprinted here] from daily reports of the performance of pile driver working on pile bridge renewals during the 1905 season, to show the number of piles driven each day and the labor cost per pile, the total labor cost per day, the delays and the average labor cost per pile for the season's work.

I have done this to show the great variation in the cost per pile, comparing one day's work with another, and yet the relative low average cost of the total work done, and, to determine a basis for estimating more closely the cost of pile renewals.

A 3,000 lb. drop hammer was used; 25 bridges were opened, the work on each bridge varying from complete renewal to one bent renewal. Driver was supplied with piling by making shipments, by bridges, as far as possible, and one car load of assorted lengths, as extras, was kept in work train.

**Engineering-Contracting*, Mar. 23, 1906.

Three hundred and ninety-one piles were driven in 32 10-hr. working days, or an average of 12.2 piles per day, the maximum cost per pile for any day was \$10.57, and the minimum cost was \$1.28. The cost per pile for the season was \$2.88. The piles varied in lengths from 20 ft. to 40 ft., and were driven 9 to 21 ft. in the ground.

The average daily expense was as follows:

	Per day.
Pile driver crew, wages.....	\$21.00
Work train, wages.....	14.50
Total, 12.2 piles, at \$2.88.....	\$35.50

In the 32 days' work, 80 hrs. were lost by delays due to traffic, etc., or about 25% of the working time.

The character of the driving varied from shell rock (requiring cast shoes) quick sand, and indurated clay to perfect material.

The train crew consisted of engineer, fireman, conductor, and brakemen.

The pile driver crew consisted of a foreman, engineer, fireman and eight men.

The men were cared for in boarding cars which were self-supporting.

The following is a type of the daily performance report:

David, Sept. 26, 1905.

Division Engineer.

Drove 16 piles Br. A188 and transferred piling in KC&MB 690 to a local flat. Worked 10 men, expense \$21.48. Delayed 2 hrs., 40 mins., as follows: 40 min. by No. 274; 50 min. running for water; 20 min. by No. 203; 40 min. by No. 204. Will finish A188 to-morrow, want orders.

Pile Driver Foreman.

Cost of Driving Piles for a Trestle, N. P. Ry.—Mr. E. H. Beckler gives the following data on driving piles for a railway trestle and three truss bridges on the N. P. Ry., at Duluth, Minn., by contract in 1884. The work was all done in the winter, and about 2,340 piles were driven, of which 460 were in foundations. The trestle was 5,000 ft. long. A pile driver, having leaders 65 ft. long, and a 2,600-lb. hammer, was used. The piles were of Norway and white pine, the average length being 51 ft. From 50 to 150 blows were struck on each pile. With a 20-ft. fall the hammer struck 7 blows per min. The penetration was 10 to 42 ft. The average cut-off was 5 ft. for the trestle piles. The pile driven engine was mounted on the driver platform to give stability and for ease of moving. A 900-lb. follower was used in driving some of the piles, but it was found to reduce the penetration of each blow about 20%, and it did not save the heads of the piles from more or less shattering.

Some piles were driven butt down, but it added 35% to the cost of driving; and it was believed that the small end, being exposed would decay faster than the butt end. Moreover, the area of the

small end was so small that the pile would not stand heavy driving without shattering.

The cost of operating one pile driver was about \$28 a day and from Dec. 11 to Mar. 5 the record of its work was as follows:

	Per pile.
202 piles (32 ft. long), 19.2 piles per day.....	\$2.25
134 piles (44 ft. long), 23.2 piles per day.....	1.65
864 piles (60 ft. long), 25.1 piles per day.....	1.50
879 piles (66 ft. long), 19.2 piles per day.....	1.95
72 piles (65 ft. long), 22.5 piles per day.....	1.85

These costs represent the cost to the contractor.

As many as 30 piles a day for 4 consecutive days were driven. The average cost of driving these 1,152 piles, it will be seen, was nearly \$1.75 per pile.

The driving was done after the ice had formed in the bay, and the pile driver was supported by the ice during driving.

The soil was 7 ft. of clay under which was sand. Before the work was begun, test piles were driven from a scow along the line of the trestle 300 ft. apart. This enabled the engineers to make out an accurate bill of pile timber for the work.

It was found that Norway pine piles stood the driving in cold weather (as low as -15° F.) much better than white pine; for, when wood freezes, it is brittle.

The test piles were nearly all broken off several feet below the ground level, by the side thrust of the ice that formed to a thickness of 4 ft. after the piles were driven. Three test piles were pulled up by the ice, although they had been driven 40 ft. into mud. The combined strength of four piles in a bent was required to resist the lateral thrust of ice pushed by the wind. The ice was unable to lift the piles once the trestle was finished.

Cost of Pile Driving, O. & St. L. Ry.—Mr. A. E. Buchanan gives the following data of work done, Oct. 22 to Dec. 17, 1889, on the Omaha & St. Louis Ry., by company labor. There were 46 days worked, the actual working time being 6 hrs. 52 mins. per day. The railway driver drove 1,267 piles in these 316 hrs. of which time 14 hrs. were lost in lowering the leads 344 times, or $2\frac{1}{2}$ mins. each time. The average time to drive a pile, it will be seen, was 15 mins. The average depth driven was 14 ft. The work was on 41 different trestles, each averaging 101 ft. long. Wages were \$2.40 for engineers, \$2.00 for fireman, and \$1.50 to \$1.75 for laborers. The cost of the 46 days' work was:

Wages	\$1,634
Fuel, etc.	262
Total, 1,267 piles, at \$1.54.....	\$1,946

The poorest day's work was 11 piles; the best, 44 piles; the average, 28 piles.

Cost of Pile Driving, C. & E. I. Ry.—Mr. A. B. Markley gives the following data relative to the cost of driving 426 piles on 16 jobs,

averaging 27 piles on each job. The work was done in 1902 for the C. & E. I. Ry., using a self-propelling railway pile driver made by the Industrial Works, Bay City, Mich. No locomotive was required as the driver could run at a speed of 10 miles an hour and pull 5 cars on a level road. The leads were 47 ft. long; the hammer, 2,900 lbs.; the hoisting rope, 2-in.; and the engine 30-hp., double cylinder. The leads could be raised in 2 mins. The engine-man received \$2.50 a day; the fireman, \$1.50; the rest of the men were laborers, except the foreman. The average cost of driving each pile was 75 cts.; and each pile averaged 24 ft. long, although the range was from 14 to 42 ft.

The Record for Rapid Driving on the O. & N. R. R.—As illustrating what can be done under favorable conditions where men are rushing their work, a record given by Mr. L. C. Fitch, Engineer of Maintenance-of-Way, Ohio & Miss. R. R., is interesting. A pile driver crew drove 28 piles (7 bents of 4 piles each) in 3 hrs., at a cost of 30 cts. per pile. The piles averaged 21 ft. long and were driven 15 ft. into the ground.

Cost of a Pile Trestle, Sheet Piles, Etc.—Mr. Henry H. Carter gives the following costs of building a trestle across a pond in Massachusetts. The work was done by contract, occupying five months, beginning November, 1882, and ending April 9, 1884. The piles were driven in bents of 8 piles to the bent, bents 4 ft. apart, and capped with 10 x 10's 25 ft. long, notched down (dapped) 2 ins. on each pile. On the caps were laid four lines of 8 x 10-in. stringers, and on these were laid the ties for a double track road for contractor's dump cars. This trestle was filled with gravel, and afterward all but the two outer piles in each bent were cut off 7 ft. below water and used as a foundation for a masonry conduit. The average length of the 3,750 piles driven was 37 ft., about 25% of the piles being over 45 ft. long. With the hammer falling about 12 ft., 318 of the piles penetrated less than 1 in. under the last blow (very hard driving); 950 piles penetrated 1.3 to 2.7 ins. under the last blow (hard driving); 2,016 piles penetrated 3 to 4 ins. under the last blow (medium driving); and 141 piles penetrated over 4 ins. under the last blow (easy driving). In general the piles were driven through several feet of very soft mud and 12 ft. into the hard bottom. The piles were driven by two floating pile drivers supported on a raft made of timbers and empty oil barrels. The cost of the work was as follows:

Making Pile Driver:

Foreman, 7 days, at \$3.25.....	\$ 22.75
Engineman, 7 days, at \$3.25.....	22.75
Laborers, 15 days, at \$1.75.....	26.25
Carpenter, 14 days, at \$2.25.....	31.50
Carpenter, 18 days, at \$2.00.....	36.00
Gins	124.00
Floats	314.95

Total making driver.....\$578.20

The cost of building this driver if distributed over the 2,638 piles

Driven, amounts to nearly 16 cts. per pile. The other costs were as follows:

Loading and Transporting Piles:

Foreman, 96½ days, at \$2.00.....	\$ 192.50
Laborers, 449 days, at \$1.75.....	785.75
Horse, 104½ days, at \$1.50.....	157.12
Sleds	3.50

Total loading, etc. \$1,128.87

Pile Driving:

Foreman, 82 days, at \$3.25.....	266.50
Foreman, 118½ days, at \$2.00.....	237.50
Foreman, 95 days, at \$2.50.....	237.50
Engineman, 87 days, at \$3.25.....	282.75
Engineman, 103½ days, at \$2.50.....	258.75
Topman, 166 days, at \$2.00.....	332.00
Topman, 17 days, at \$1.75.....	29.75
Deckhand, 116½ days, at \$2.25.....	262.12
Deckhand, 255½ days, at \$2.00.....	511.50
Deckhand, 280 days, at \$1.75.....	490.00
Laborer, 20 days, at \$1.00.....	20.00
Carpenter, 177 days, at \$2.25.....	398.25
Carpenter, 172 days, at \$2.00.....	344.00
Freight on pile drivers	75.00
Coal, 35 tons, at \$6.40.....	224.00
Use of plant, 120 days, at \$1.50.....	170.00
11 M spruce braces, at \$14.....	154.00
87½ lbs. spikes in braces, at 3 cts.....	26.16
Tools	120.00

Total driving \$4,861.98

Piles:

3,638 spruce piles (av. 27 ft. each), at \$2.26.. \$8,221.88

Grand total (excl. driver)..... \$14,022.53

The loading and transporting of the 3,638 piles cost \$0.22 per pile. The driving cost \$1.30 per pile, the average number of piles driven being 20 per day. The cost of each pile averaged \$2.26. The total cost of each pile driven was \$4.04, including cost of making scow, interest on driver, labor, fuel and cost of pile. The use of plant at \$1.50 a day is too low an estimate under ordinary conditions.

The cost of the materials and labor for caps, stringers and ties (there were no sway braces) was as follows:

Transporting Timber:

Foreman, 19 days, at \$2.00.....	\$ 38.00
Laborer, 89 days, at \$1.75.....	155.75
Laborer, 4 days, at \$1.50.....	6.00
Horse, 20 days, at \$1.50.....	30.00
Sled	1.50

Total transporting timber..... \$ 231.25

Labor on Caps and Stringers:

Foreman, 16 days, at \$3.25.....	\$ 52.00
Foreman, 20 days, at \$2.50.....	50.00
Carpenter, 60 days, at \$2.25.....	135.00
Carpenter, 58 days, at \$2.00.....	116.00

Total labor on caps, etc..... \$ 353.00

<i>Caps and Stringers:</i>	
159 M spruce, at \$16.10.....	\$2,559.90
12 M spruce bolsters, at \$18.50.....	182.00
2.6 M spruce plank, at \$14.00.....	50.40
10,490 lbs. bolts, at 2½ cts.....	282.23
3,330 lbs. bolts, at 3 cts.....	114.90
88 lbs. spikes, at 3 cts.....	2.64
Building derricks	5.00
Tools	28.50

Total labor and mtl. for caps and stringers \$3,559.57

The cost of transporting timbers to the trestle (\$231.25) applies not only to the 175 M of caps and stringers, but also to 24 M of ties and 27 M of sheet piling and wales, making the cost of transporting practically \$1 per M. The other labor involved in placing the caps and stringers (\$353) after delivery, is equivalent to \$2 per M, making a total of \$3 per M for the labor on the caps and stringers. The cost of placing the ties was as follows :

<i>Placing Ties:</i>	
Laborer, 4½ days, at \$1.00.....	\$ 4.50
Laborer, 6 days, at \$1.50.....	9.00
Laborer, 51½ days, at \$2.00.....	103.50
Total placing ties	\$117.00

<i>Ties:</i>	
24.18 M spruce ties, at \$14.....	\$338.52
540 lbs. spikes, at 3 cts.....	16.20

Total labor and mtl. \$471.72

From this it appears that the cost of placing ties was nearly \$5 per M (or 21.3 cts. per tie) to which must be added \$1 per M for loading and transporting.

The cost of sheet piling was as follows:

<i>Sheet Piling:</i>	
25.5 M sheet piling, at \$18.60.....	\$474.30
1.2 M spruce wales, at \$16.00.....	19.20
205 lbs. spikes, at 3 cts.....	6.15
Interest on pile driver, 16 days, at \$1.40.....	22.40
3 tons coal, at \$6.40.....	19.20
Foreman, 16 days, at \$3.25.....	52.00
Engineman, 16 days, at \$3.25.....	52.00
Topman, 16 days, at \$2.00.....	32.00
Deckhand, 16 days, at \$2.00.....	32.00
Deckhand, 40½ days, at \$1.75.....	71.81
Carpenter, 32 days, at \$2.00.....	64.00

Total sheet piling

The cost of driving the 25.5 M and placing the 1.2 M was nearly \$13 per M. This sheet piling was 4-in. tongued and grooved, driven for two culverts.

The cost of sawing, dapping (notched 2 ins.) and fitting 280 caps for 280 pile bents of 6 piles to the bent was as follows: Cost to saw off piles, and fit caps, \$2.95 per cap, or \$2 per M (for each cap was 10 x 10 ins. x 18 ft.). The piles were sawed off at the bottom of a wet trench, and it cost 90 cts. per bent to saw away the earth. Carpenters received \$2.50, laborers \$1.25, and foreman \$3.50 a day. The gang consisted of 1 foreman, 3 laborers and 4 carpenters.

These caps were covered with a platform of 4-in. spruce plank run lengthwise of the trench, laid to break joint, and spiked to the caps with 3-in. cut spikes. This platform was laid with a force of 1 foreman, at \$3.50; 8 laborers, at \$1.50, and 1 carpenter, at \$3.50. The cost of laying 900 M was \$7.40 per M. The contractor doing this work failed.

Cost of a Pile Docking.—This work consisted in driving a row of oak piles, 25 ft. long and 5 ft. centers, to an average depth of 10 ft. into gravel. The piles were sheeted on the rear with 3-in. oak plank laid horizontally and breaking joints. A waling piece, of 10 x 12-in. oak, was bolted along the front face of this docking, and anchored back to stone deadmen. The anchor rods were 1½-in., spaced 10 ft. apart. Back of this docking an earth fill was placed, but the following costs relate only to the timber work. A pile driver, mounted on rollers, and operated by a friction-clutch engine, was used. The daily cost of operation was as follows:

7 men, at \$1.50	\$10.50
1 foreman	3.00
1 pair of horses	1.50
Rent of driver and engine.....	3.00
¼ ton coal, at \$4.....	1.00

Total, 10 piles driven, at \$1.20.....\$12.00

The piles were of oak and two of the men peeled and pointed them and square-sawed the heads. The horses were used to drag the piles up to the driver. There was some grading and scaffolding work necessary to provide a level runway for the driver. The foreman was not a good manager, and the cost was much higher than it should have been. On one day when the work was pushed and when conditions were favorable, 25 piles were driven.

The labor cost of placing the sheet planking and wale piece was \$4.50 per M, about 80% of the timber being the 3-in. planking. This work was done by common laborers working in pairs, at \$1.50 each per 10-hr. day. The piles were not always plumb and seldom spaced exactly, so that a measuring pole had to be used to fit each plank, and every plank had to be sawed separately by the men. Had the engineer so designed the work that the planks could have been set on end, like sheet piling, all this fitting and sawing of individual planks could have been avoided, with consequent reduction in the cost. Moreover there would have been less waste of plank. Such a design would have necessitated two more small-sized wale pieces, but it would have made easy the removal of any single plank at any time for repairs due to rotting. In boring the oak wale pieces and piles with a 1½-in. ship auger, a man would bore 12 ins. in 5 mins. It took 5 mins. for two men to cut off a 10 x 12-in. oak stick using a crosscut saw.

It may be well to note that the plans called for the driving of 3 x 8-in. oak sheet piling to a depth of 5 ft. by hand, using wooden mauls. It was found impossible to drive these planks more than 2 ft. into the gravel without battering the heads to pieces.

Data on Driving Plumb and Batter Piles, New York Docks.—Mr. Charles W. Raymond gives the following data on the driving of piles for docks, Hudson River, New York City, prior to 1880: Piles were driven with a scow pile driver, the scow being 3 x 20 x 42 ft., provided with leaders 50 ft. long. The engine was a 10-hp. friction-clutch hoisting engine, with double cylinders, 6 x 12 in. The boiler was 15 hp. upright. A crew of 8 men worked 8 hrs. per day for the city, and drove 10 to 15 piles per day. The piles averaged about 65 ft. long, and were driven 55 to 60 ft. below mean low water, penetrating about 10 ft. of gravel and cobbles (6-in. and less) that were filled in over the dredged area before driving. Then the piles penetrated about 25 ft. of river muck, making a total penetration of 35 ft. There was no difficulty in driving through the cobbles and gravel without brooming the piles. All piles were sharpened, and their heads were squared. To indicate the kind of driving, two records of 50 piles show that 230 blows of the hammer were required to secure a penetration of 22 ft., or 180 blows to secure a penetration of 22 ft. The last foot of penetration required 13 to 14 blows of a 3,000-lb. hammer falling 8 ft. (not freely, but with the hammer rope).

A special driver, with leaders inclined 1 to 6, was used to drive batter piles, and the average number of piles driven per day was about half as many as in driving plumb piles, or 5 to 7 piles per 8-hr. day. The number of blows per batter pile was somewhat greater than per plumb pile, but by no means enough greater to account for the slower driving, which was probably due to difficulty in getting the batter pile properly started.

Data on Driving Piles for Docks, New York.—Mr. Eugene Lentilhon states that in 1896 the following comparative records were made with a drop hammer and a Vulcan steam hammer: The driving was for a dock on the Hudson River, New York City, and was very hard driving, the material being 10 ft. of cobbles underlain by sand and gravel. The piles were spaced 3 ft. apart, and driven from scows. The drop-hammer, friction-clutch machine had a crew of 10 men. It required 175 blows of a 3,200-lb. hammer falling 10 ft. to drive a pile; and 15 blows were struck per minute, hence the actual time of hammering a pile was about 13 mins. The piles were 55 to 60 ft. long and penetrated 21 to 23 ft. The crew averaged 12 piles per 10-hr. day.

As compared with this crew of 8 men, using a Vulcan steam hammer, averaged 18 piles per 10 hrs. The machine weighed 8,400 lbs., and the striking piston weighed 4,000 lbs. and had a drop of 3½ ft. It struck 60 blows per minute, and some piles required as many as 1,200 blows. Mr. Lentilhon does not make it clear why the steam hammer was more effective than the drop hammer. It is probable, however, that there were fewer delays in straightening up the pile during driving when a steam hammer was used. He states that there were two objections to the steam hammer, one of which was the frequent loss of the "cap" or "saucepan," or "hood," by dropping into the water, and the rapidity with which the "cap"

was worn out. Only 38 piles were driven with each cap before it was worn out. The second objection was the impracticability of driving crooked piles.

Cost of Pulling Piles, Driving Piles and Timberwork.*—In 1899 the city of New York let a contract for making alterations to the temporary bridge over the Bronx River near Westchester avenue, Bronx Borough. The contract price was \$950. The work consisted of the tearing out of the old pivot pier, cutting off one span of the west trestle approach and adding one span to the east side. Fig. 6 shows the extent of the work.

The old pivot pier was constructed of piles driven to rock through four or five feet of hard material, probably disintegrated rock. The piles were sway braced, were capped by 12 in. x 12 in. timber

Fig. 6.

and had a 6 in. deck on top of the caps. A fender rack about 94 ft. long was also removed. This rack consisted of piles, 8 ft. center and timber, 3 in. x 12 in., bolted to the piles.

The contractor's plant consisted of a pile driver and scow and a land driver operated from the scow. According to the terms of the contract all timber in good condition could be used over again. Work was begun June 14, and the weather was favorable for good work.

The first work done was the tearing out of the old pile pivot pier and the fender rack. In this work the scow pile driver was used in pulling the piles, about 45 piles being removed in this manner. Such of these piles as were in good condition were used in the new work. In addition one span of pile trestle was cut off in the west trestle approach, the timber being sawed off close to the ground. A total of about 10 M ft. B. M. was removed, the labor cost being as follows:

**Engineering-Contracting*, June 13, 1906.

	Hours.	Rate, cts.	Total.
Foreman	48	45	\$21.60
Engineman	24	35	8.40
Dock builders	96	27½	26.40
Watchman	30	15	4.50

Total 10 M ft. at \$6.09.....\$60.90

It was necessary to excavate a small amount of mud in order to allow the pile driver to float in sufficiently near the pivot pier, and also to allow the placing of the sway bracing as low as possible. The depth of the cutting was 3 ft. and about 30 cu. yds. of material was removed. The labor cost was as follows:

	Hours.	Rate, cts.	Total.
Foreman	4	45	\$1.80
Engineman	2	35	.70
Dock builders	8	27½	2.20
Watchman	2	15	.30

Total, 30 cu. yds. at 16.6 cts.....\$5.00

In driving the piles the scow pile driver and the land driver were used, the latter, however, was used only in driving the piles in the bank bents, 8 piles being so driven. In all 83 piles were driven. The piles were of spruce, about 25 ft. long, and were rather slender. They were driven through about 5 ft. of disintegrated rock, above which was soft mud, to solid rock. It took from 20 to 35 blows of the hammer to drive each pile. The hammer was raised by a friction hoist, and fell with hoist cable attached.

The labor cost of driving the piles is shown in the accompanying table.

LABOR COST OF DRIVING THE PILES.

	Hours.	Rate, cts.	Total.	per pile.
Foreman	82	45	\$ 36.90	\$0.44
Engineman	41	35	14.35	.17
Dock builders	171	27½	47.03	.57
Watchman	40	15	6.00	.07
Total			\$104.28	\$1.25

LABOR COST OF FRAMING AND PLACING TIMBER.

	Hours.	Rate, cts.	Total.	Cost per M. ft. B. M.
Foreman	166	45	\$ 74.70	\$5.06
Engineman	88	35	34.80	2.36
Dock builders	365	27½	100.38	6.78
Watchman	128	15	19.20	1.30
Total			\$229.08	\$15.50

In framing and placing timber about 14,800 ft. B. M. of yellow pine lumber was used. Some of this was new and some was taken from the old work. The piles were cut off and capped, and the stringers and floor in the approaches and the deck of the pivot pier were placed. A railing was built on the approaches and the sway braces and fender rack were bolted into position. Little framing was done. The labor cost of this work is shown in the accompanying table.

The total cost of the work is shown below:

<i>Labor:</i>	
Tearing out old work.....	\$ 60.00
Excavation	5.00
Driving piles	104.28
Framing and placing timber.....	229.08
Total labor	<u>\$398.36</u>
<i>Materials:</i>	
53 piles at \$2	\$106.00
Timber, 3.6 M ft. B. M. at \$30.....	108.00
Bolts, spikes, etc., 900 lbs. at 5 cts.....	45.00
Total	<u>\$259.00</u>
<i>Operating Expenses:</i>	
Towing	\$ 20.00
Coal for pile driver, 2½ tons at \$4.....	10.00
Repairs to plant.....	10.00
Total operating expenses.....	<u>\$ 50.00</u>
Total cost	<u>\$679.00</u>

As stated previously the contract price was \$950.

Work of this character is generally expensive because of the small gang of dock builders employed. The engineman's wages and plant expense, therefore, form a large percentage of the total cost.

Cost of Driving and Sawing Off Piles.—Mr. Eugene Lentilhon gives the following relative to a pile foundation for a concrete sewer, built by the New York City Dock Dept. The piles were driven by a scow driver with a 3,400-lb. hammer, which worked 85 days. Wages were \$2.30 for laborers, \$3.50 for engineman, and \$3.00 for dock-builders, per 10 hrs. The average was 8 piles driven per day, at a cost of \$3.90 for labor of driving. The piles were sawed off 1 ft. below mean low water. The dock builders fastened small battens on opposite sides of a pile to guide the saw, and frequently two men during a good low tide sawed off 2 piles. The cost of sawing off was \$1.28 per pile.

Data on Driving With a Steam Hammer and Sawing Off Piles.—Mr. Sanford E. Thomson gives the following data on driving and sawing off piles for the Cambridge Bridge, at Boston, in 1901. A Warrington steam hammer, made by the Vulcan Iron Works, of Chicago, was used by the contractors. It weighed 9,800 lbs., and the striking part weighed 5,000 lbs. With 90 to 100 lbs. of steam, the hammer would strike 60 to 70 blows per minute, falling by gravity. The top of the leaders of the scow driver was 75 ft. above the water surface. After a pile was well down, an oak follower, 14 ins. square and 30 ft. long, was placed on the pile to complete the driving, so that the pile head was left 18 ft. below the water surface. The average 10-hr. work of a driver was 100 piles, but on one day as many as 212 piles were driven in 9 hrs. The piles were 40 ft. long and driven in hard clay.

The piles were cut off 15 to 34 ft. below low water by a rotary

saw mounted on another scow. A 40-hp. engine running at 150 revolutions per minute was geared up to the saw shaft so as to drive the saw at about 450 revolutions per minute. A 42-in. saw was mounted at the lower end of a hollow vertical shaft 4 ins. in diameter and 60 ft. long. This shaft was supported by three pillow-block bearings which were bolted to a spud 14 ins. square and 60 ft. long; so that when the spud was raised or lowered the saw shaft moved with it. The pulley on the saw shaft was arranged to slide on a spline or key, so that the shaft could be raised without raising the pulley. The belt from the pulley ran to another pulley mounted on a short vertical jack-shaft, provided with a bevel gear wheel meshing with another bevel gear wheel on a horizontal shaft driven by the engine. This horizontal shaft was geared to the engine with a link belt. This machine sawed off 600 to 800 piles per 10-hr. day. The spruce piles were 10 ins. diameter.

Cost of Driving Piles for a Swing Bridge.—A steel highway swing bridge, 240 ft. long, and 18-ft. roadway, was to be supported on a pier in the center of the river. The piles were Washington fir, driven to an average depth of 20 ft. in gravel. The penetration under the last blow of a 2,400-lb. hammer, falling freely 27 ft., was 3 to 4 ins. A scow pile driver was used, and the force to operate it was as follows:

	Per day.
1 engineman	\$ 3.00
1 man tripping hammer	1.75
2 men guiding pile	3.50
2 men making ready the next pile.....	3.50
$\frac{1}{2}$ foreman	2.50
$\frac{1}{2}$ ton coal, at \$9.....	3.00
Total per 10 hrs.....	\$15.25
Rent of driver	6.00
Total	\$21.25

This force averaged 26 piles per 10-hr. day. The foreman supervised another gang of men, so that half his wages were charged to this work. The piles were neither peeled nor sharpened, for I found no economy in so doing. There were 42 piles in the pier, and twice as many more in the pier protection bents upstream and downstream, which also served as falsework upon which to build the bridge. The piles in these bents were sawed off, capped and sheathed with plank. Two men with a cross-cut saw would saw off 30 of the piles in the bents in 10 hrs., at about 12 cts. per pile. The cost of sawing off the piles below water for the pier is given in the next paragraph.

Cost of Sawing Off 42 Piles Under Water.—It was necessary to cut off 42 piles, 4 ft. below extreme low water for the pier work just described. A gravel bar occupied the site of the pier, and, although the water was about 4 ft. deep over the bar at the time of pile driving, it was necessary to dredge this bar at least 4 ft. deeper. A hole 4 ft. deep, and 27 ft. square on a side, was dredged with an ordinary drag scraper equipped with long handles and hauled by the pile-driver engine. The men operating the scraper walked on

a raft. It took $3\frac{1}{2}$ days of the pile driver crew above given, to do this dredging, at \$31 per day, or \$74. The 42 piles were driven in this hole, after driving 4 piles above the hole and sheeting them with plank to act as a temporary sheer dam to prevent the river current (3 miles per hr.) from filling in the hole with gravel during pile driving. The 42 piles were cut off about 8 ft. under water with a circular saw mounted on a shaft driven by the pile-driver engine. A saw, shaft, pulleys and belt were bought for this purpose and rigged up by the pile-driver crew. It took them 3 days to rig the saw and cut off the 42 piles. The hole had not been dredged deep enough and the gravel that had washed in dulled the teeth of the saw requiring frequent raising to resharpen it. Moreover, the engine did not have sufficient power to drive the saw at high speed, and the piles were as much chewed off as sawed off. All these, however, are conditions apt to be met in similar work on small jobs. The 3 days' sawing cost \$64, or \$1.50 per pile.

Data on Sawing Off Burlington Bridge Pier Piles.—Mr. C. Hudson gives the following description of the method used in sawing off several hundred piles for the Burlington Bridge pier, in 1868:

The piles when driven, were sawed off by machinery. On each side of the pier, and a few feet away from it, a row of piles, perhaps 6 or 8 ft. apart, was driven. These were capped, and upon the cap was placed a traveler 12 ft. wide, arranged to be moved from end to end of the pier on these caps. Upon this traveler was another and smaller one, arranged to run upon it and across the pier. This last traveler carried a vertical shaft in a properly braced frame. This shaft carried at its lower end a circular saw about 36 ins. in diameter. The shaft could be raised or lowered as required, and was driven by means of a beveled gear from a horizontal shaft on the little traveler. A long belt extended the whole length of the large traveler, around a pulley on this horizontal shaft, and another guide pulley, so arranged that the shaft was turned regardless of the position of the little traveler. An engine on a boat alongside the pier was the motive power.

The little traveler was fed across the pier by means of a set of small blocks on each side, and a line which ran around a wheel shaft like a ship's steering wheel. By this means the traveler could be moved either way, and could thus cut off a row of piles running one way, and then, by feeding back cut the next row, the large traveler having been moved back to reach it. In this way 12 or 15 piles were cut off per hour. The efficiency of the saw under water is, of course, very much less than in the air.

Cost of Pulling and Driving Piles for a Guard Pier.—The pile protection, or guard pier, of an old draw bridge, across a tributary of the Hudson River, was removed and new piles were driven. I sublet the work, and the following are the actual costs to the subcontractor:

The number of piles pulled was 200, and the time required was 10 days. A scow pile driver was used, the engine being a friction-clutch machine, and the hammer weighing 2,300 lbs. To pull the

piles, a pair of heavy triple-sheave blocks were used. The pulling was easy, the piles being only 10 to 15 ft. in rather soft ground. The daily (10-hr.) cost of operating the scow was as follows:

	Per day.
1 captain of driver.....	\$ 3.50
1 engineman	2.00
3 men, at \$1.80.....	5.40
$\frac{1}{2}$ ton coal, at \$3.....	1.00
Rent of driver	5.00
Total, 20 piles pulled, at 80 cts.....	\$16.90

This same crew then drove 200 new piles in 20 days, or 10 piles per day, at a cost of \$1.60 per pile. The piles were driven 15 to 20 ft., and were 20 to 25 ft. long after cutting off. The slowness of the driving was largely due to delays caused by navigation at high tide, the channel being so narrow that the driver had to drop down with the tide to make way for boats to pass, and then pull back against the tide. On some days the driver was interrupted in this way as many as 8 times.

After the piles were driven and cut off, a 6 x 12-in. wale piece was bolted on each side of the piles, entirely around the guard pier, the wale piece being 1 ft. below the top of the piles. Another (but single) wale piece was bolted to the piles, on the outside, at low water. To these wale pieces, 3 x 12-in. sheeting planks were spiked upright; and two more lines of 6 x 12-in. walings were bolted through the sheeting and inside wale pieces, to hold the sheeting in place. The 1-in. bolts were countersunk. The timber for the wale pieces was yellow pine in 16-ft. lengths, and had to be scarfed with a 12-in. ship lap on each end, and drift bolted twice. This scarfing was expensive work, beside causing a 4% loss of timber at the scarfs. If longer lengths than 16 ft. had been used, the cost of labor and the waste of timber would have been less. Beside the wale pieces and sheeting, there were 6 x 12-in. timbers bolted on each side of every fifth bent of piles; and the center piles of the bent were capped, lengthwise of the guard pier, with a 12 x 12-in. cap. There were nearly 30,000 ft. B. M. of yellow pine timber all told, which cost \$22 per M delivered.

For this timberwork the same crew was used as for pile pulling and driving, except that one more timberman, at \$1.80, was employed, making the daily cost \$17.70. The crew averaged only 1,300 ft. B. M. per day, at a cost of nearly \$14 per M for framing and placing all the timber. They were slow workers, and there were delays due to navigation.

Cost of Drawing Foundation Piles and Sheet Piles.—The following is a very brief abstract of a long illustrated article in *Engineering-Contracting*, May 3, 1907, by Mr. Charles M. Ripley, on the anchorage of the Manhattan Bridge.

Sheet Piling and Excavation.—The first work done was the excavation of the foundation pit and the driving of the foundation piles. This work was done by the J. & F. Kelley Co., as subcontractors. Sheet piling 12 ins. thick and from 20 to 30 ins. wide was driven all around the anchorage and so as to give about

4 ft. clearance on the sides and at the front and to be close against the footing masonry at the rear. It was driven by a Vulcan steam hammer. There were about 360 ft. of sheeting around the pit; the depth of the sheeting being about 25 ft. we have then some 258 M ft. B. M. of lumber in the sheeting proper not counting in waling or bracing.

Exact figures of this work are not available for publication, but the sheet piling gang working with one driver usually consisted of one foreman at \$4 per day, one engineer at \$4 per day and five or six dock builders receiving \$2.50 per day on land and \$3.50 per day on water. An 8-hr. day was worked and about twelve sheet piles were driven per machine per day. Assuming an average depth of sheeting of 25 ft. we have 300 lin. ft. of piling driven per day, or about 3,600 ft. B. M., at a labor cost of:

	Total	Per ft.	Per M. B. M.
1 foreman at \$4.....	\$4.00	1 1/4c	\$1.60
1 engineer at \$4.....	4.00	1 1/4c	1.60
6 dock builders at \$2.50.....	15.00	5c	6.00
Total	\$23.00	7 3/4c	\$9.20

The amount of excavation inside the cofferdam was approximately 45,000 cu. yds. Taking the amount of sheeting given above as 258,000 ft. B. M., we have 174 cu. yds. of excavation for every 1,000 ft. B. M. of sheet piling, or 5.75 ft. B. M. of piling per cubic yard of excavation.

Foundation Piling.—The foundation piles were driven by a plant of four 3,500-lb. drop hammer drivers with 45-ft. leads. These machines were mounted on skids and rollers in two horizontal directions and traveled across the work, driving a strip of piling as they progressed. In addition to the drop hammer drivers there were two steam hammer drivers similarly mounted, one a 5-ton and one a 4-ton Vulcan hammer. Every sixth row of piles across the foundation pit was driven by light drop machines and was then capped with a 12 x 20-in. timber. Two of these parallel timbers formed the track for the drivers. Five rows of piles were driven from each track.

In a few cases a water jet was used to assist in the driving. Altogether 4,430 piles were driven. The piles were an average of 25 to 30 ft. long, 14 ins. in diameter at the banded end and 9 ins. in diameter at the point. The piles were driven to a refusal of a quarter of an inch and the work was so arranged that 16 piles were driven by each machine per 8-hr. day.

The gang on each machine worked an 8-hr. day and was organized as follows:

1 foreman at \$4.....	\$ 4.00
1 engineer at \$4.....	4.00
6 laborers at \$2.50.....	15.00
Total labor	\$23.00

With each machine driving 16 piles the labor cost of driving per 25 to 30-ft. pile was \$1.43 per pile. It was found in this work

that the steam hammer drivers were about $2\frac{1}{2}$ times as rapid as the drop hammer drivers.

Cost of Pulling Piles.—In 1898 I had a contract for pulling piles from the bed of a river. Several hundred piles were pulled with a tripod machine, with gear wheels and triple blocks that multiplied the power 270 times, as shown on page 1047. A rope passed from the drum of the machine to a 4-hp. hoisting engine, which was thus able to pull piles driven 27 ft. into the ground. It cost \$100 to make two of these machines and about \$300 more for blocks and tackle and repairs.

The crew for each puller was 3 laborers, 1 boss and 1 engineman, so that the cost of wages and $\frac{1}{4}$ ton of coal was \$10 per day. About 700 piles were pulled with two machines, the average depth of pile being 12 ft., although many were 25 ft. The average day's work per machine was 15 piles making the cost of labor and fuel about 70 cts. per pile. The men worked in water up to their knees and were provided with rubber boots costing \$100, which, with the \$400 paid for machines and repairs, made \$500, or about 70 cts. more per pile, or a total of \$1.40 per pile.

Chains that were wrapped around the piles in pulling were made of $1\frac{1}{4}$ -in. iron, with a breaking strength of about 100,000 lbs. The strain was so great in pulling the longest piles that the chains were frequently broken.

Cost of Blasting Piles.—Several hundred piles were removed by blasting, in addition to the 700 that were pulled as above described. The piles had been cut off at the water's surface many years before, and our contract required the removal of the piles at least 4 ft. below the surface of the low water, which was equivalent to about 2 ft. below the bed of the river. Long ship augers were used to bore holes $1\frac{1}{4}$ ins. in diameter and $4\frac{1}{2}$ ft. deep, down the core each pile. Each laborer averaged 7 such holes bored per 10 hrs. in white oak piles, or 20 ft. per day. The cost per pile for boring and blasting was:

Labor boring, 15 cts. per hr.....	\$0.21
1 lb. of 70% dynamite.....	0.20
$\frac{1}{4}$ lb. of 40% dynamite.....	0.03
5 ft. of fuse	0.03
1 cap	0.01

Total per pile.....\$0.58

Each pile was loaded with two sticks of 70% dynamite and one stick of 40%. This charge would cut off the largest pile and hurl the butt 75 ft. in the air. Occasionally a very tough pile would be splintered, and had to be pulled. This added cost of pulling averaged 10 cts. more per pile, which might have been avoided by making all three sticks 70% dynamite.

Cost of Driving and Pulling Test Piles.*—A pile was driven every 50 ft. across the Hackensack River, N. J., to test the nature of the bottom. Three 90-ft. piles were used, and were pulled after driving.

**Engineering-Contracting*, July 18, 1906.

The cost of the work includes the cost of pulling as well as driving.

A scow driver was used, and the work was done at cost plus 10% for superintendence. The total number of feet penetrated by the piles was 624, or about 57½ ft. as an average of the 11 piles, 8 of which were driven to rock. The material penetrated was mud, sand and clay.

The work occupied 4½ days, of which 1½ days were spent in transporting the driver to the site of the work and removing it from the work after completion. The cost was as follows:

Foreman, 4½ days at \$4.....	\$ 18.00
Machine men, 45 days at \$3.....	135.00
Watchman, 4 nights at \$3.....	12.00
Total	\$165.00
Add 10 per cent for profit.....	16.50
Total	\$181.50

This is at the rate of 20 cts. per lin. ft. of penetration for driving and pulling, but it does not include the cost of coal. Coal was probably less than ½ ton per day, or say \$10 for the whole job, or less than 2 cts. per foot.

The cost of materials was as follows:

3 piles, 90 ft. long, at \$25.....	\$75.00
2 spruce piles, 52 ft. long, for use as followers, at \$4.....	8.00
4 pile bands, at \$2.50.....	10.00
Total	\$93.00
Add 10 per cent for profit.....	9.30
Total	\$102.30

This is equivalent to about 16 cts. per lin. foot of pile penetration. The total cost was therefore:

	Per ft. Penetration.	Per Pile.
Labor	\$0.30	\$16.50
Coal02	0.90
Materials16	9.30
Total	\$0.48	\$26.70

It will be noticed that there were 10 men and 1 foreman on the driver, which is an unusually large number; and it will also be noted that the wages paid the "machine men" were very liberal.

Since only 3¼ days were actually spent in driving, the average day's work was 3 piles driven and pulled. If an ordinary scow driver crew of 6 men at \$2, and 1 man at \$4, had been employed, the daily wages would have been \$16. To which add \$2 for coal and \$6 for rental of plant, making a total of \$24 per day for driving and pulling 3 test piles, or \$8 per pile. Even \$8 per pile would be a high cost for such work, when done by contract, if the cost of moving the driver to and from the site of the work is not included.

In view of the valuable information gained at small expense by driving test piles, it is surprising that engineers do not oftener test

the bottom of rivers in this way before drawing plans and specifications for bridge foundations, trestles, etc. When a contract has been awarded for foundations, the first thing that the contractor wants to do is to order his piles. The engineer usually refuses to furnish a bill of materials until enough piles have been driven to determine the character of the bottom. This delays the whole work, and adds materially to the contractor's expense. Moreover, it usually results in a change of specified lengths of piles, and a corresponding change in the ultimate cost of the job. The time to drive test piles is *before* the award of a contract, not *afterward*.

Cost of Driving Piles for a Shore Protection.*—Mr. Daniel J. Hauer gives the following:

The work was done by contract. The piles were for the foundation of a reinforced concrete shore protection, consisting of a pilaster spaced on 12-ft. centers and a curtain wall 6 ins. thick cast between the pilasters. Two piles were driven for each pilaster, thus making a space of 12 ft. between each set of piles. The two piles were 18 ins. center to center. This spacing is somewhat unusual, as foundation piles are seldom driven on more than 6-ft. centers, which means more piles to drive with less moving. There was nothing difficult in the driving, and no great obstacles to overcome. The work was along the shore of a tidewater bay, and except in a few places out of reach of the water. Only once for an hour or so was the work stopped by high tide. Nearly half of the work was through marshes, the rest of the driving being in stiff clay. But little cribbing had to be done, the runways being placed on blocks on the ground. Where any grading had to be done to allow the machine to be rolled ahead, it was done by other forces, and has not been included in the costs given.

The piles were not sawed off, but were driven by a follow head to the proper depth, which was 0.6 ft. below mean low water, the foundation pit having just been excavated. This was made possible by the fact that the piles were not capped, but the heads of the piles were imbedded in the concrete. The piles were delivered within easy reach of the machine by teams, this being done by another contractor.

The lengths driven varied from 10 to 30 ft., less than 5% being the last named length, while many were only 15 to 20 ft. long, more than half being but 10 ft. The average length was 12½ ft. The pile driver had leads 33 ft. high, which were bolted to a bed frame of 12 x 12-in. timbers, 5 ft. wide and 24 ft. long, upon the other end of which sat the 10-hp. hoisting engine, it being a single cylinder double drum engine with two winch heads. One drum operated the hammer fall and the other the pile hoisting line. The top of the machine was guyed by two lines run to anchors a hundred feet or more away on either side, and run through a block on the head, the other end of the line being fastened to a davit on the bed frame; this allowed of the guys being easily slackened

**Engineering-Contracting*, July 27, 1906.

or tightened. The bed frame rested on two steel rollers with holes in the end to take bars in order to roll the machine. The hammer weighed 2,000 lbs.

The machine was old and in a dilapidated condition. The fittings around the boiler and engine leaked both steam and water; the leads were badly racked; towards the end of the job the hammer frequently jumped out of them. The rollers, too, were old ones, and, besides being cracked, one had a flat side on it, so as to prevent it rolling easily. All these things materially delayed the work at times and added much to the expense of operating the driver. The condition of the boiler and the indifferent engineers who ran it, coupled with the fact that most of the work was done in the winter season, made the consumption of coal and water large.

The cost of such a plant new at the present time, including machine ropes, small tools, blocks and anchors, would not be over \$1,200. Thus, if a plant rental of \$5 per day was charged against the job, with work for the outfit for 100 to 120 days in the year, the entire cost of the plant would be cleared in two seasons. This charge seems to the writer to be ample, but it is customary to hire such a plant for \$10 per day for short jobs.

The work will be divided into two parts, as this division will allow of a comparison of costs, driving the piles under two different foremen, also under different weather conditions; the first being done in excellent weather in the autumn, the second during the winter months. The rates of wages were also different for the men. The foreman and engineer were paid weekly and were not allowed overtime, as they lost no time. The work was seldom stopped even during stormy weather, their daily wage, prorated from the weekly rate, is used. In example No. 1 the wages paid were as follows:

Foreman	\$2.50
Engine runner	2.00
Pile driver men	2.25
Laborer	1.50

In example No. 2 the daily wages were:

Foreman	\$2.50
Engine runner	2.00
Pile driver men	2.00
Laborers	1.50
Cart and driver	2.00

Example 1.—These piles were driven during good autumn weather. The foreman was competent and attended to his work. The machine was brought to the site of the wall on a scow, which was beached, and the engine, leads and so forth skidded off and the parts of the machine assembled. This, with the building of a camp, consumed three days, and the labor items are included in the cost of the pile driving. This foreman drove 472 piles, their average length being 15 ft. The engine used 325 lbs. of coal each day of 10 hrs., the coal costing on board of the scows \$2.50 per ton. Both water and coal were brought to the work on scows, a tow costing

\$15 per trip, the tug bringing a load and returning with the empties. A laborer carried the coal and water ashore from the scow in a row boat and delivered it at the engine. One man was kept at this continually, and he is listed in the cost under coal and water laborer. The monthly rental of two small scows at \$50 per month is given under "scows and tugs." In listing the cost each item was kept separate and is as follows, per pile driven:

	Per pile.
Foreman	\$0.151
Engineer	0.121
Pile driver men.....	0.830
Labor preparing piles.....	0.106
Coal and water laborer.....	0.090
Scows and tugs	0.278
Watchman	0.052
Total labor	\$1.622
Coal, 325 lbs. daily	0.056
Plant (int. and deprec.).....	0.320
Total	\$1.997

The piles were squared on the end and prepared to be put in the leads by one man, who had no trouble in keeping this work ahead of the driving. One man attended to the water and coal, while seven men placed the piles in the leads, guided it down, placed the runways and assisted in moving the driver ahead. To accomplish this an anchor was placed in the ground ahead to act as a dead man, and with a line run from it to the winch head on the engine, the machine was pulled ahead on the rollers, the crew assisting with bars.

For the entire job an average of 17 piles were driven each day, but as three days were consumed in starting, and three additional days were used in moving the machine as explained later, the average number of piles driven for each day of driving was 21. The average length of the pile was 15 ft. They were delivered in longer lengths and sawed into two pieces of the desired length.

After working a number of days the pile driving work was stopped on account of the necessary excavation not having been made, and it was decided to move the machine back to the starting point and drive piles in the opposite direction in order to build more of the shore protection. The machine was turned around and moved in the manner as described above for a distance of 1,300 ft. Although the contractor was paid full account for this, yet the cost has been included in the figures given above. The time consumed in moving was three days, and the cost for labor, plant, coal, etc., was as follows:

Labor	\$65.25
Plant rental	15.00
Coal	1.70
	\$81.95

This makes a cost per pile of 17.3 cts. for moving.

During the course of the job it was necessary to move the water

and coal scows along the shore, so the water and coal tender could reach them quickly to get his supplies. The cost of this work is given under pile driver men, and was not separated from the other work.

The foreman, as stated, was a competent and intelligent one, and handled his men with some thought. He endeavored to keep up his runways and make the work light for his men, realizing that more work was accomplished in this manner.

In addition to the cost per pile, a record was kept of the cost per lineal foot of pile driven, which was:

	Per lin. ft.
Foreman	\$0.019
Engineer	0.009
Pile driver men.....	0.057
Preparing piles	0.007
Coal and water laborer.....	0.006
Scows and tugs.....	0.020
Watchman	0.002
Total labor	\$0.112
Coal, 325 lbs. daily.....	0.004
Plant (int. and deprec.).....	0.022
Total	\$0.138

Example II.—After the winter weather had set in, the necessary excavation having been made, the work was resumed. A new foreman was put in charge of the job. After moving the machine from where it was last used to the new site, the driving commenced. This move was also paid for by the railroad company. The distance was 2,500 ft. The driver was rolled 100 ft. onto an embankment, where an ox team could be brought to it, was knocked down and hauled by the yoke of oxen hitched to a timber cart. The bed frame and engine making one load, the leads another, and the hammer, ropes and small tools making a third load. The machine was then set up for work. The time consumed was five days, a day and a half of which time the ox team worked. Fifty dollars were paid for their services. The total cost of moving was:

Labor	\$ 74.75
Plant rental	25.00
Coal	4.37
Ox team	50.00
	\$154.12

This cost is also included in the cost of driving as given below. The average length of the piles driven was 11 ft. For the actual number of days of driving the average number driven per day was 15, while for the whole time the average number was 13. Scows were not used for coal and water, but the water was hauled from a well about half a mile distant, and the coal from another job a mile and a half away. A one-horse cart was used for this purpose, a laborer serving the engine from the supplies so hauled. The cost per pile was:

	Per pile.
Foreman	\$0.194
Engineer	0.150
Pile driver men.....	0.864
Labor preparing piles.....	0.182
Coal and water laborer.....	0.110
Carts	0.110
Watchman	0.018
Total labor	\$1.813
Coal, 500 lbs. daily.....	\$0.070
Plant (int. and deprec.).....	0.880
Total	\$2.263

The cost per lineal foot of pile driven was as follows:

	Per lin. ft.
Foreman	\$0.014
Engineer	0.018
Pile driver men.....	0.078
Labor preparing piles.....	0.016
Coal and water laborer.....	0.010
Carts	0.027
Watchman	0.005
Total labor	\$0.163
Coal, 500 lbs. daily.....	0.005
Plant (int. and deprec.).....	0.035
Total	\$0.203

A comparison of the costs of these two examples of similar work is extremely interesting. The weather was favorable in the first case, but the rate of wages for pile driver men were higher and the average length of pile was longer, yet every item of cost was larger in the second example. The size of the crew was the same, but instead of one man preparing the piles two men did this work, which about doubled the cost; but this extra man made one less man working with the machine; yet that cost is increased. This and the other labor costs being enlarged is due to less work being done each day. The larger consumption of coal was due to the weather being colder and to bad firing, as will be noted later. Taking into consideration the wages the increased cost of Example II over I should have been little, if any.

The foreman in the last work was incompetent, yet a shrewd fellow. A representative of the contracting firm only visited him a few times a week, and then rarely stayed with him more than an hour. The foreman took advantage of this, and by "grand stand plays" stood well with the firm, yet shamefully neglected his work; in fact, he and his crew "soldiered."

A record was kept of the time used in doing the various kinds of work each day, and in order to illustrate how it is possible for a foreman to rob his employer this record is reproduced for several days:

December 27.—Moving runways ahead and placing them, 2 hrs.; rolling machine, 3 hrs. and 25 mins.; boiler foaming, so it would not steam, 30 mins.; driving piles, 4 hrs. and 10 mins. Total time worked, 10 hrs. and 5 mins. Crew: Foreman, engineer, 10 men,

cart and driver, 2 men preparing piles, 1 man coal and water. Foreman and 2 men went away at 8:10 to see that some timber was not afloat; came back at 9:45. (This was not necessary.)

January 8.—Moving runways and placing them, 50 mins.; rolling machine, 1 hr. and 35 mins.; driving piles, 1 hr. and 45 mins.; boiler foaming, so it would not steam, 30 mins.; out of steam through negligence of engineer, 20 mins.; 5 hrs. consumed in fixing machine, such as tightening bolts and rods, adjusting lines, most of which was unnecessary; 1 hr. should have adjusted everything that needed it. Total time worked, 10 hrs. Crew: Foreman, engineer, 11 men, cart and driver, 1 man coal and water, 2 men preparing piles.

January 15.—Waiting for steam from 7 o'clock until 10:25, 3 hrs. and 35 mins., during which time runways were placed; rolling machine, 1 hr. and 15 mins.; waiting for steam in afternoon, 30 mins.; making a follower, 1 hr. (the writer has frequently made one in 10 mins.). Total time worked, 8 hrs. and 30 mins. (30 mins. stolen by whole crew). Foreman away from work, 1 hr. Crew: Foreman, engineer, 8 men, cart and driver, 1 man on water, 2 men preparing piles for 2 hrs.

These are records picked at random, and no comment is needed regarding them, save that if accurate cost data are kept on work such rascality and incompetency could not occur. Another feature that added to the cost of Example II was that the foreman, instead of heading his machine in the direction in which he was moving, had the back end first, which prevented him from using an anchor and the winch head of his engine in moving the driver, as the other foreman did. Because he was used to moving a machine backward, owing to the fact that with such a driver the piles are frequently left standing above the surface of the ground, he could not see that when the piles were driven below the surface it was an advantage in moving ahead to have his machine with the leads in that direction. Even when he was advised to prod his machine properly he ignored the advice, and before finishing the job he had to turn the machine, as the last piles were driven so close to a high bank there was not room enough to take the driver between the piles and the bank. This turning cost \$14.70 for the labor, as it consumed 6 hrs. of time.

The following shows how the time of the crew was spent for a week, the cost of each item of work being given. The week was picked at random and is in many ways representative. The total cost of labor was \$148.97, divided as follows:

Fixing runways	\$ 12.04
Rolling machine	18.96
Preparing piles	22.00
Serving coal and water.....	6.25
Hauling coal and water.....	16.50
Waiting for steam.....	6.81
Fixing machine, etc.....	32.96
Driving piles	26.75
Time loading	2.70
	<hr/>
	\$148.97

Although this work was mismanaged many lessons can be learned from it.

Cost of Driving Wakefield Sheet Piling, Chicago, Ill.*—The matter of constructing intercepting sewers for the purpose of diverting sewage into the Chicago Drainage Canal was taken up by the City of Chicago in the latter part of 1897. In August, 1899, bids were received for the construction of the south arm of that sewer system. All these bids were rejected, and in 1901 the city undertook the construction of this section of the system, employing day labor, and having all work done under the supervision of its own engineers.

We shall give a brief description of the manner and methods of driving the piling for Section G, which extended from 39th to 51st streets, and for Section H, between 51st and 63d streets. As this was the city's first experience in construction work on a large scale, it was necessary to secure an entirely new plant. Accordingly, the city built, with its own labor, a turntable drop hammer pile driver, for use on Section G. The driver had a hammer weighing 3,000 pounds, and was equipped with a 7 x 10-in. double-drum hoisting engine and a duplex steam pump for jetting. The machine cost \$1,300.

As the sewer for a distance of about 2,500 ft. would be under the shoal water of the lake, and for the rest of the distance very close to the water's edge, it was necessary to use sheeting during construction, which would be practically water tight. Accordingly, Wakefield sheet piling was used, the lumber employed in its construction being 2 in. x 12 in. x 20 ft. Norway and Georgia pine, surfaced one side and one edge. For most of the work Southern pine was used. In practice, however, it was found that Norway pine would stand 50% more blows under a drop hammer, and, in consequence, Norway sheet piling was used where there was difficult driving.

About 12 ft. below city datum the clay line was found; immediately above this was a layer of fine blue sand mixed with short clay. This stratum when loose and wet acts very much like quicksand. Above this stratum was ordinary lake sand. The sand was very solid and compact, owing to the action of the waves of the lake, but with the exception of gravel spots the seepage was small, considering the nearness to the lake. The first sheeting was driven nearly to the bottom of the proposed excavation; but later it was found that sheeting driven 4 to 5 ft. into the clay would do sufficiently well. In order to have the sheeting left to a sufficient height above the line of the lake for protection against high water, tides, etc., 16 ft. of material was used with some exceptions.

In the bracing, 10-in. x 12-in. x 22-ft. stringers and 10-in. x 10-in. x 20-ft. braces were used. Three sets of stringers and braces were found sufficient for most of the distance. In some places, however, it was necessary on account of bad ground and swelling clay, to re-

**Engineering-Contracting*, March, 1904.

inforce both stringers and braces. Throughout the entire work, 2-in. Dunn screw-braces were used.

In construction, the top set of stringers and braces followed the scraping and leveling. The distance between the sheeting was 22 ft. for the 18-ft. conduit and 21½ ft. for the 15½-ft. conduit. A clearance of about 9 ins. between the sheeting and sewer brickwork was allowed.

As was stated previously the city had built a turntable driver for use on this section of the work. In the operation it was found practical to swing the driving apparatus about once every day. Ordinarily about 50 ft. of sheeting in each direction was driven on one side, and then 50 ft. in each direction on the other side. A water jet for jetting to the clay was used with marked success. Ordinarily, after jetting to the clay and getting the piling into position, four or five blows of the hammer were sufficient. In many cases isolated rocks, about 1½ ft. in their largest dimensions, were found from 2 ft. to 8 ft. below the surface; these were disposed of by jetting a large hole beside them. The piles were held in place during driving by a ½-in. buck line, attached to the front drum of the hoisting engine, and leading through the sheaves attached to the pile driver and sheeting in place, to and around the pile to be driven. In making each Wakefield pile, 50-penny wire spikes were used. Half-inch carriage bolts were tried as fastenings, but it was found that the carpenters could make at least twice the number of sheet piles when 50-penny wire spikes were used. Eight to ten spikes were used per pile. The pile-driving crew followed the gang setting the top braces; and, on straight work at least, it was planned to have a distance of about 400 ft. between the pile driver and the excavating derrick, because when the driving was too near there was trouble with seepage water from the jet.

In ordinary driving, the crew averaged about 90 pieces of sheeting for 8 hrs. This is equivalent to 45 ft. of trench sheet piled. The largest day's work was 120 pieces of sheeting placed. On some days, however, when such obstructions as piers were encountered, not more than 12 pieces of sheeting were driven; this occurred once perhaps in 300 to 400 ft.

The pile driving crew consisted of the following:

	Per day.
1 foreman, \$100 per month.....	\$ 4.16
1 engineman, \$4.80 per day.....	4.80
1 fireman, \$2.50 per day.....	2.50
2 carpenters, \$3.60 per day.....	7.20
4 laborers, \$2.50 per day.....	10.00
1 jet man, \$3.00 per day.....	3.00
1 ladder man, \$3.00 per day.....	3.00
2 winch men, \$3.00 per day.....	6.00
Total	\$40.66
1 ton coal	2.99
Total, 10.8 M, at \$4.03.....	\$43.56

As about 45 ft. of trench was sheet-piled per 8 hrs., the labor

cost per linear foot of sewer amounted to \$0.90. The labor cost per pile was 45 cts. The bill of materials required for the average amount placed in an 8-hr. day was as follows:

10.8 M ft. B. M. 2 ins. x 12 ins. x 20 ft. timber	
at \$22	\$237.60
900 spikes, at \$2.65 per 100	23.85
Total materials	\$261.45

Adding the total labor cost and the total cost for material we have \$305.01 as the total cost of 90 piles. From the above it will be seen that the cost per pile amounts to \$3.38, of which \$0.47 was for labor. The cost per 1,000 ft. B. M. of piling was about \$28.

Another pile driver was built by the city for the construction of the sheet piling in that section of the intercepting sewer between 51st and 73d streets, known as Section H. This machine was also constructed on a turntable and could be swung from one side of the trench to the other. In order to secure a good foundation bearing for the runways and rollers the span of the lower bed was made 34 ft. The driver was equipped with a 7 x 10-in. double-drum engine, had 40 ft. leads and a 2,500-lb hammer. A jet pump, with water tank, 20 ft. jet tube and other appliances were also among the equipment.

As in the first case, the sheeting was of the ordinary Wakefield pattern, made up of 2-in. x 12-in. plank, fastened together, however, by 60-penny spikes. The method of driving this sheeting was as follows: The top set of stringers and braces were put in place for 100 ft. to 200 ft. in advance, and about 18 ins. below the surface of the street; a second set of stringers, parallel with the street, made up of 4-in. x 12-in. plank, was put in about 5 ins. outside of the main stringers and on the same level as those inside, for the purpose of keeping the sheeting in line. All braces and timbers were then covered with sand to prevent their being washed out by the water jet. The sheeting used was 18 ft., 20 ft., 22 ft. and 24 ft. long, depending on the depth of the clay. The top of the sheeting was driven to about 1 ft. below the street grade, and the lower end was from 2 ft. to 4 ft. in the clay. For each pile a hole was jetted to the clay line, and as soon as the jet tube was pulled out, a pile was dropped into place and pulled over the tongue of the previous pile. Excellent alignment was obtained by using a "buck line" to hold the sheeting in place while being driven. In this case the "buck line" consisted of an old cable having a loop at one end to go over the head of the pile, the other end of the cable, after passing through a couple of snatch blocks, being attached to the hoisting engine.

From 75 to 110 piles were driven in eight hours, the number depending somewhat on the character of the ground; 85 piles, however, were considered a fair day's work.

The pile driving crew and their rate of wages were as follows:

	Per day.
1 foreman, \$100 per month.....	\$ 4.16
1 jet man, \$3.50 per day.....	3.50
2 ladder men, \$2.50 per day.....	5.00
2 winch men, \$3.00 per day.....	6.00
1 pile man, \$2.75 per day.....	2.75
1 engine man, \$4.80 per day.....	4.80
1 fireman, \$2.75 per day.....	2.75
4 laborers, \$2.50 per day.....	10.00
2 carpenters, \$4.20 per day.....	8.40
Total labor per day.....	\$47.36
1 ton coal	2.90
Total, 10.2 M, at \$5.....	\$50.26

An average of 85 piles per day were driven, which is equivalent to about 42.5 ft. of trench piled. This was at the rate of \$1.11 per foot of trench for the labor cost. The labor cost per pile was 55 cents. The bill of material required for 85 ft. of piling was as follows:

10.2 M ft., 2 in. x 12 in. x 20 ft. timber,	
at \$25	\$255.00
850 spikes, at \$2.65 per 100.....	22.52
Total	\$277.52

From the above it will be seen that the total cost for material and driving was \$3.85 for each pile, of which \$0.55 was for labor. The labor cost per 1,000 ft. B. M. of piling was about \$32.

Cost of Piling, Cross References.—Data on wooden piling will be found in the sections on Bridges, Railways, Sewers, etc. Data on concrete piles will be found in the section on Concrete, and on steel piles in the section on Steelwork. Consult the index under Piles.

Estimating Cost of Brush Revetment.—A very effective method of protecting the banks of a river from scour is a revetment consisting of a brush mattress on that part of the bank below extreme low water and a stone slope wall, or hand placed riprap, on the part of the bank above low water. Brush when always submerged never rots, but it is useless to carry it much above low water for it soon decays. Such brushwork is a sort of timberwork, and is therefore placed in this section of the book.

Engineers very commonly record costs of revetment in the terms of the lineal foot of bank as the unit, and, while such a unit is desirable, it is more important to reduce the costs of the mattress either to the square (100 sq. ft.) or to the square yard as the unit, for widths of mattresses vary greatly. So also should the cost of the slope wall or slope pavement be reduced to the square yard and the cubic yard measured in place in the slope wall. While data are given in the following pages as to the cost of slope wall paving, the reader should consult the section on Masonry for more complete discussion and data.

In making roughly approximate estimates it may be well to remember that rough slope wall paving seldom costs more than \$2.00

per cu. yd. in place (unless stone must be brought long distances), and that a thickness of 9 ins. ordinarily suffices, thus giving a cost of 50 cts. per sq. yd., but when stone is secured near the work may not cost 30 cts. per sq. yd.

Brush mattresses can ordinarily be made and ballasted with stone for about the same cost per square yard as a rough stone slope wall, that is for 50 to 50 cts. per sq. yd., as a rather high cost, to 30 cts. per sq. yd. as a low cost attained only when brush and stone for ballast are near at hand. However, rough estimates of this kind need not be made, since the following pages give all details.

Cost of Brush Mattress and Slope Wall, Missouri River.—Mr. W. R. De Witt gives the following relative to bank revetment built in 1901, on the Missouri River, by the company forces of the Chicago & Alton Ry. In general the work was similar to that done by the Government.

The river bluffs were first graded to a slope of 1:2, using a water jet. A barge carrying a force pump, delivered water through a 4-in. hose at 100 lbs. per sq. in., to a 1½ or 1¾ in. nozzle. The nozzle is fitted with a lever and swivel, the pin of which is dropped into a piece of iron pipe previously driven in the ground at the top of the bank. This gives the nozzleman full control. Two laborers shift the hose. When the upper bank is graded and most of the earth thrown out into the river current, the nozzle is moved down the slope near the water surface, and the grading continued under water. The gang thus engaged is as follows:

	Per day.
1 engineman	\$ 2.75
1 fireman	1.50
1 watchman	1.25
1 nozzleman	2.25
2 laborers, at \$1.25	2.50
Total	\$10.25
Fuel and supplies	2.25
Grand total, 800 cu. yds., at 1½ cts.	\$12.50

I have assumed the individual wages, but the totals are as given by Mr. De Witt.

This crew graded 100 lin. feet of bank about 50 ft. wide (about 800 cu. yds.) per 10 hr. day. Hence it costs \$1.25 per lin. ft. for grading, which is an amazingly low cost.

The grading was followed closely by the work of weaving a willow brush mattress 36 ft. wide, 32 ft. of which were under water when it was sunk. Two barges 20 x 50 ft. were lashed end to end, and a platform and set of ways built on them. Another barge loaded with brush furnished the supply of willows. The weaving is done on the inclined ways. When the top of the ways is reached the men lift the mattress and allow the boat to drop down stream until the edge of the mattress is at the foot of the ways, and so on.

The brush is 1 to 2 ins. diam. and 15 to 25 ft. long, and is woven in and out, bundles of willows being grouped together, as

in braiding hair. The stitch is like that on a cane seated chair. The mattress is 12 ins. thick, and has a selvedge on both edges. It is strengthened and held in place by wire cables. Five pairs of $\frac{3}{8}$ -in. galv. cables run longitudinally (up and down stream), one cable of each pair under the mattress and one on top, and a single cable is run along the inshore selvedge. Similar pairs of cables are transversely at intervals 16 ft. 8 ins. (one under and one on top), and are carried up the bank and anchored to deadmen at the top. Where the longitudinal and transverse cables cross, an iron clip is used to fasten them together. The clip consists of two $\frac{7}{16}$ in. bolts, each bent at right angles, and the threaded end of one bolt passing through a loop in the end of the other, a nut on each serving to bind them. Before fastening the clips, the slack is taken out of the cables with block and tackle.

The gang engaged in making the mattress was as follows:

- 1 foreman.
- 10 laborers skilled in weaving.
- 10 brush passers.
- 3 hand brush to brush passers.
- 6 laborers handling cables.
- 3 laborers digging and filling holes for deadmen.
- 1 water boy.

—
\$3 total.

These men averaged \$1.50 each per day, or \$49.50, and they built 90 lin. ft. of mattress, 86 ft. wide, or 7,740 sq. ft. per day. Hence each man averaged 235 sq. ft. per day, at a cost of \$0.64 per 100 sq. ft.

A barge load of stone is swung across the mattress, and stones weighing 100 to 200 lbs. are distributed over it and it is sunk. A gang of 30 men empty a barge of 150 cu. yds. of stone in 2 hrs., which sinks 200 lin. ft. of mattress. This is at the rate of $16\frac{1}{2}$ cu. yds. of stone per man per 10 hr. day.

The inshore edge of the mattress is then filled with spalls for the distance that is 3 ft. above low water and 3 ft. below low water.

The slope wall paving is begun at a point 2 ft. above high water, and shingled down the slope, reversing the usual practice of beginning at bottom and moving up. The reason for this is that the stones thus lean away from the river, and they catch and hold all sediment as the river rises and falls. The stone is delivered in barges and wheeled in barrows up runways. The stones are so tilted that the wall is about 3 ins. thick at the top of the bank and 12 ins. at the water's edge. The paved slope is 54 ft. long, and the following gang will pave 100 lin. ft., or 5,400 sq. ft., or 600 sq. yds. per day.

	Per day.
4 pavers, at \$2.50.....	\$10.00
28 men loading and wheeling, at \$1.50.....	42.00
Total	\$52.00

The average thickness is 9 ins., hence 150 cu. yds. of stone are

laid by this gang per day, at a labor cost of 9 cts. per sq. yd., or 24 cts. per cu. yd., or \$1 per 100 sq. ft. The work is very rough, no stone dressing being required, as is evident from the fact that each of the 4 pavers lays 28 cu. yds. per day.

Over the pavement is spread a 2-in. layer of spalls or crushed stone, filling all cracks to prevent washouts from surface drainage.

The following was the average cost of 3,250 lin. ft. of bank revetment.

Grading Bank:	
Labor	\$0.10
Fuel, etc.	0.03
Total grading bank	\$0.13
Weaving Mattress (88 ft. wide):	
0.6 cords brush at \$1.75 deliv.	\$1.05
8 lbs. $\frac{3}{8}$ -in. galv. cable at \$0.04	0.32
$\frac{1}{4}$ iron clip at \$0.05	0.02
0.06 deadmen (12 x 12 ins. x 4. ft.) at \$1.	0.06
Labor	0.55
Total weaving mattress	\$2.01
Ballasting Mattress:	
0.75 cu. yds. stone at \$1 deliv.	\$0.75
Labor	0.07
Total ballasting mattress	\$0.82
Paving Bank (54 ft. wide):	
1.5 cu. yds. stone at \$1 deliv.	\$1.50
Labor	0.52
Total paving bank	\$2.02
Spawls on Pavement:	
0.47 cu. yds. spawls at \$0.50	\$0.24
Labor	0.15
Total spawls	\$0.39
General Expense:	
Administration	\$0.13
Care of plant	0.07
Current repairs to plant	0.02
Hire of plant	1.00
Surveys	0.05
Ice	0.03
Towage, other than brush and stone	0.08
Total general expense	\$1.43
Grand total	\$6.80
Add 10% for contingencies	\$0.68
Total for estimate	\$7.48

The plant consisted of a grading boat, a small steam boat, a mattress boat, and six barges (25 x 100 ft.) if all material is transported by steam, as was the case here.

Cost of Brush Mattress and River Bank Revetment.—Mr. Charles Le Vasseur is authority for the following: On the Mississippi River brush mattresses are now used only to protect that part of a bank that is under water, usually for a width of 250 ft. Then the

bank above water level is graded to a 1:1 slope by a water jet, and paved roughly with stone. The brush mattress is woven by men working on scows, the scows extending out into the river 250 ft. The scows are provided with "ways" on which the mattress rests, and, by pulling the scows along as the mattress is woven, a continuous mattress is launched into the river along the shore. The brush is made into small bundles (10 or 12 ins. diam.), or fascines bound with No. 12 wire (no brush being over 3 ins. diam.), and these are laid side by side and bound with $\frac{1}{4}$ in. steel wire, woven in and out, being drawn taut by a block and tackle. On top of the mattress are placed rows of poles, 16 ft. apart, extending up and down stream. They are lashed to the fascines with No. 7 silicon bronze wire every 5 ft., and at intermediate points with steel wire. These poles prevent the stone ballast from slipping off the mat when it is sunk on a steep slope. Rock is wheeled onto the floating mat in barrows on run planks from stone barges. The materials and labor per 100 sq. ft. of mattress are:

- 1.5 cords brush.
- 0.08 cords poles.
- 0.75 cu. yd. stone.
- 3 lbs. No. 12 galv. wire.
- 6 lbs. $\frac{1}{4}$ in. galv. wire strand.
- 4 lbs. 5/16 in. galv. wire strand.
- 1 lb. $\frac{1}{2}$ in. galv. wire strand.
- 1.35 clamps, 5/16 in.
- 0.16 clamps, $\frac{1}{2}$ in.
- 0.8 day labor building and sinking.

It costs about \$6.80 per 100 sq. ft. of this mattress, or about \$17 per lin. ft. of river bank, the mattress being 250 ft. wide. In addition it costs \$1.25 per lin. ft. of bank to grade, with a hydraulic jet, the bank above the water edge. The hydraulic grader is a barge carrying a pumping plant discharging 2,000 gals. per min. under pressure of 170 lbs. (125 lbs. at the nozzle) through a 4 in. hose to ($1\frac{1}{4}$ or $1\frac{1}{2}$ in.) nozzles. This grading of the upper bank is not done till the mattress is sunk. Then the upper bank is paved with 0.3 cu. yd. of stone per sq. yd., at a cost of \$10 per lin. ft. of bank. This makes the total cost \$28.25 per lin. ft. of bank.

In grading the bank the nozzle is handled by men on top of the bank, directing the jet downward, and it cuts the slope as true as if it had been planed.

Cost of Brush Revetment Ballasted With Concrete.*—The Department of Engineering of the State of California is now using a type of flexible revetment as a protection to river banks that is quite a departure from the kind previously employed by the department. The method that was formerly used was to make a mattress of

**Engineering-Contracting*, Mar. 24, 1909.

brush fascines usually woven with wire or cable, and weighted down with loose rock laid on top of the mattress. If the slope of the bank below the water line, where it could not be graded, was steep, no rocks would lie in the mattress. Should erosion take place at the lower edge of the mattress, the latter would drop down, the rocks roll off and then the rush would rise with the water, be torn loose and carried away.

The type of revetment now constructed by the Department of Engineering developed from a plan originated by Nathaniel Ellery, state engineer, and was successfully used by him in bank protection work along the Eel river in Humboldt county, California.

The plan consists of a mattress composed of brush fascines 8 to 12 ins. in diameter and about 20 ft. long, bound with wire. These fascines are laid double, breaking joints, and woven over and under with three galvanized wire "strands" or cables, $\frac{1}{4}$ in. in diameter. Galvanized anchor cables, $\frac{3}{4}$ to 1 in. in diameter, are laid on the slope extending from the barge floating in the stream to upon or over the levee to a safe point where a line of concrete blocks is sunk in the soil and connected by a $\frac{1}{2}$ to $\frac{3}{4}$ -in. diameter galvanized cable. These anchor cables are fastened to the line attaching together the line of "deadmen," or as called by the department, anchor blocks. The anchor cables are spaced about 8 ft. centers and are attached on the water end to a line of cable passing through heavy concrete blocks made on the barge. These concrete blocks are called by the department sinker weights. After this skeleton of cable and concrete work is set and ready, the mattress is woven on top of these cables and the mattress is tied or lashed to the anchor cables beneath the mattress every 4 ft. After the mattress is woven to its desired width another cable $\frac{1}{4}$ in. in diameter and galvanized, is drawn down over the mattress directly over the anchor cable. It is fastened to the anchor cable at 6 or 8-ft. intervals through the brush. The ends of this top cable are fastened to the anchor cable on the land end by a cable clip just above the brush mat and the water end is made long enough to reach the sinker block where it is fastened. Also, just at the water edge of the mat the anchor cable and the top cable are fastened together.

Above the water the mattress is woven in place on the ground which has been prepared by grading to a uniform slope. When the water's edge is reached the weaving takes place on the cables suspended over the water by placing planks on the cables. The barge is held off shore by spars or struts which are held taut by shore lines to the barge. After the mattress is completely woven, blocks of concrete 2 or 3 ft. square and from 6 to 12 ins. thick are placed on the mattress, the size and distribution of which depends upon the figured buoyancy of the brush and the force of the current to be resisted. These blocks are molded in place on the mattress and thoroughly fastened on the top cable usually with a turn or knot of the cable firmly embedded in the concrete. When the mat is thus made ready the barge is shoved away, permitting the structure to sink and conform to the bank slope. The mattress so

made will, because of its flexibility, conform to the variations in the slope of the bank below the water where it could not be graded. Should the current cut under the edge of the mattress the weights will drop down, carrying the mattress down as the earth is washed away, and all—mattress and weighting—being secured by cables to the anchorage on shore, will continue to hang over the bank like a curtain. No weights can roll off and release the brush.

This type of revetment was used on Sherman Island in two places where the shore had been eroded by waves, and successfully protected the bank. The revetment on Sherman Island consisted of a mattress of willow brush in two sections, 176 ft. and 352 ft. in length, making a total length of 528 ft. The average width was 75 ft., and the average thickness 16 in. The superficial area was 4,400 sq. yds. and the cubic contents 1,984 cu. yds. A total of 182 cu. yds. of concrete was used. The mattress was built from a barge, the upstream sections overlapping the previously laid section down stream. The work was done in 1908 by contract on the basis of cost plus 8 per cent. The cost of the work was as follows:

COST OF REVETMENT.

	Total.	Per cu. yd.	Per sq. yd.	Per lin. ft.
Labor	\$ 324.70	\$0.113	\$0.051	\$0.432
Brush	1,489.70	.750	.338	3.865
Cable and clips.....	903.94	.455	.205	1.746
Equipment	96.10	.048	.022	.182
Concrete	1,313.35	.663	.301	2.535
Inspection	74.20	.037	.017	.142
Contractor's com.	215.40	.109	.049	.421
Grand total	\$4,316.39	\$2.175	\$0.983	\$8.217

In addition, grading costing \$75, or \$0.017 per sq. yd. of mattress, was done. This makes the total cost of the revetment \$4,391.39, or \$1.00 per sq. yd.

The item labor is for the mattress work and covers 715 hrs. of work, or 36 hrs. per cu. yd. of revetment, 0.16 hr. per sq. yd. and 1.35 hrs. per lin. ft. Labor was paid \$2.50 per day of 8 hrs. The item brush is for 1,983.99 cu. yds. of brush at 75 cts. per cu. yd. The item cable and clips is for 37,375 ft. of cable. The item equipment covers the following items:

Barge hire and watchman.....	\$170.00
Launch hire, 16 days	65.00
Watchman, 17 days.....	27.50
Moving barge, checking gravel, etc.....	13.85
Material, telephone calls, etc.....	10.97
Total	\$297.22

This total was distributed over the revetment work proper and the concrete work. The barge hire and watchman for barge cost \$10 per day and it cost \$10 for tonnage to the barge. The item inspection covers surveys and inspection and was spread over the revetment work proper and the concrete.

The itemized cost of the concrete was as follows:

	Total.	Per cu. yd.
Labor, 995 hrs.....	\$ 311.26	\$1.729
Cement, \$1.27 per bbl.....	305.64	1.695
Gravel, \$1.25 per cu. yd.....	218.00	1.211
Lumber and nails	84.07	.466
Equipment	201.22	1.118
Inspection	103.56	.576
Contractor's commission	89.60	.498
Total	\$1,313.35	\$7.292

Another flexible brush mattress was placed on Brannans Island, the work being done by contract on the basis of cost plus 8%.

The revetment consisted of a mattress of willow brush in three sections, 2,620 ft., 187 ft., and 175 ft., respectively; total length, 2,982 ft.; average width, 66½ ft.; average thickness, 14 ins.; superficial area, 21,892 sq. yds.; cubic contents, 8,586 cu. yds. This mattress was built from a barge, in sections 225 ft. in length, the up-stream sections overlapping on the previously laid section downstream. The concrete used was 700 cu. yds. The unit cost of the work was as follows:

CONCRETE.

	Total cost.	Cost per cu. yd.
Labor	\$1,287.01	\$1.830
Cement	1,161.29	1.659
Gravel	864.35	1.235
Lumber and nails.....	374.91	0.535
Equipment	1,198.25	1.711
Inspection	262.42	0.375
Commission	382.86	0.547
Total	\$5,553.09	\$7.901

REVETMENT.

	Total cost.	Cost per cu. yd.
Grading	\$ 229.59	\$0.010
Labor	1,411.33	0.064
Brush	6,440.51	0.293
Cable and clips.....	5,727.24	0.262
Equipment	1,281.32	0.056
Concrete	5,531.09	0.252
Inspection	262.41	0.012
Commission	1,197.89	0.055
Total	\$22,081.38	\$1.004

At Merkeleys, a revetment was constructed to protect a river bank which had begun to cave badly. The work was done in 1908 by contract on the basis of cost plus 8%. The revetment consisted of a mattress of willow brush in four sections, aggregating 774 ft. The average width was 40 ft. and the average thickness was 8 ins. The superficial area was 3,440 sq. yds. and the cubic contents 1,912 cu. yds. The concrete amounted to 145 cu. yds. The method of construction was the same as at Brannans Island, previously mentioned.

The unit costs of the work were as follows:

CONCRETE.		Per cu. yd.
	Total.	
Labor	\$ 332.17	\$2.296
Cement	289.58	1.997
Rock	243.61	1.681
Lumber, etc.	213.75	1.474
Equipment	196.75	1.357
Inspection	46.75	.322
Contractor's commission	101.00	.698
Total	\$1,423.61	\$9.826

REVETMENT.		Per sq. yd.
	Total.	
Labor	\$ 346.01	\$0.0716
Brush	1,434.39	.416
Cable and clips	1,025.41	.3926
Equipment	196.50	.0572
Concrete	1,423.61	.4145
Inspection	50.08	.0146
Contractor's commission	299.00	.0872
Total	\$5,177.10	\$1.561

A similar revetment was also constructed in connection with the work of closing a break in a levee on the Kripp Farm in the city of Sacramento. The work of closing the break in the levee was done by day labor, the state engineer's department hiring a dredge and crew at \$160 per day of 22 hrs. The levee required to close the break was 1,600 ft. long, 24 ft. maximum height and 16 ft. wide on top, containing 102,489 cu. yds. of earth. The actual cost of building the levee, including superintendence and inspection was \$5,667.64, or 5½ cts. per cu. yd.

The revetment was built by contract on the basis of cost plus 10%. It consisted of a mattress of willow brush, 710 ft. long, 40 ft. wide and 12 ins. thick. The superficial area was 3,400 sq. yds. and the cubic content was 1,172 cu. yds. The concrete used amounted to 100 cu. yds. The mattress was made on the bank and in place. The unit costs of the work were as follows:

CONCRETE.		Cost per cu. yd.
	Total cost.	
Labor	\$247.06	\$2.47
Cement	163.79	\$1.64
Gravel	135.00	1.35
Lumber	41.53	0.41
Equipment	129.28	1.29
Inspection	25.00	0.25
Commission	78.66	0.73
Total	\$824.32	\$8.24

REVETMENT.		Cost per sq. yd.
	Total cost.	
Labor	\$ 174.18	\$0.042
Brush	921.05	0.272
Cable and clips	548.92	0.163
Concrete	824.32	0.269
Inspection	148.00	0.044
Commission	184.48	0.054
Total	\$2,773.95	\$0.843

Cost of Brush Mattresses.*—Maj. D. Fitch gives the following:

Brush mattresses, riprapped with stone, were used to protect the bank of the Upper White River, Arkansas, in connection with building a timber crib dam. The cost of riprapping is given in detail in the section on Masonry, and the cost of the timber crib is given elsewhere in this section. Work was done by Government forces, laborers receiving \$1.50 per 8-hr. day.

The following was the cost of the protection mattress work:

PROTECTION MATTRESS (293 Sq. Yds.).

	Unit cost.	Total.	Per sq. yd.
Riprap, 320 cu. yds.....	\$0.74	\$237	\$0.808
Inspection of riprap, 320 cu. yds.....	.008	3	.010
Cutting and hauling brush, 169 cords....	1.669	282	.962
Weaving and sinking, 293 sq. yds.....	1.344	394	1.344
Total		\$916	\$3.124

The total labor time for cutting and hauling 160 cords of brush was 150 days, the work done per man per day being 1.09 cords; the total labor time for weaving and sinking 293 sq. yds. of mattress was 223 days, the work done per man per day being 1.31 sq. yds.

450 Ft. Bank Revetment.—This work included the construction of 200 brush mats, the grading of the bank and paving it with riprap, the cost of the various items being as follows:

Brush Mattress:	Unit cost.	Total.	Per square.
Wire, etc.		\$108	\$0.54
Riprap, 336 cu. yds.....	\$.74	248	1.48
Cutting and loading brush, 289½ days..	531	2.60
Weaving and sinking, 213½ days.....	387	1.93
Inspecting 336 cu. yds. riprap, 4 days..	7
Total, 200 squares.....		\$1,281	\$6.40

Work done per man per day was 0.93 squares wove and sunk.

Summary for 450 ft. bank revetment:

	Total.	Unit cost.
Brush mattress, 200 squares.....	\$1,281	\$6.40
Grading bank, 450 lin. ft.....	229	.51
Riprapping bank, 1,044 cu. yds.....	1,000	.96

A total of 450 lin. ft. of bank was graded, the total labor time being 123 days at a cost of \$229 or \$0.51 per lin. ft. Each man graded 3.6 lin. ft. of bank per day.

Summarising we get the following as the cost of the 450 ft. revetment:

Brush mattress	\$1,281
Grading bank	229
Paving bank	1,000

Grand total, 450 lin. ft., at \$5.58.....\$2,510

Cost of Mattress and Slope Wall, M., K. & T. Ry.†—Mr. R. M. Garrett is authority for the following:

The revetment put in by the Missouri, Kansas & Texas along the

**Engineering-Contracting*, May 6, 1908. p. 284.

†*Engineering-Contracting*, March 31, 1909.

Missouri River, for shore protection, is built like that along the Missouri River, which have been put in by the Missouri River Commission, and averages about 60 ft. in width. The first work put in by this company was during 1897, and extends from the east city limits of St. Charles down the river for 2,000 ft. A rock dike was first built out into the river, and a boom made of heavy timbers was anchored to the lower side of the dike, and laid parallel with it. From this boom the mat was started, having its full width at the beginning. The mat was first woven and sunk, and then the bank was graded by hydraulic power to a slope of 3 to 1, and then paved from the top down.

In 1903, work was extended 3,000 ft. down the river, and was done in the same way as the first section, with the exception that the mat was anchored at the starting point with piles instead of the boom.

In 1906, revetment was again extended 7,200 ft. On this last section the bank was graded to a slope of $2\frac{1}{2}$ to 1 in advance of weaving the mat, as considerable trouble had been experienced on former work, on account of material from the bank covering the mat, so that a connection between paving and mat could not be properly made.

Grading on this section was done with a small hoisting engine on a barge, as follows: A derrick was erected on a barge, having a boom long enough to reach the top of the bank to be graded, a No. 3 wheeler scraper pan was pulled along this boom from the barge to the top of bank, by a mule on the bank, and was held in place by two men and filled, and then dragged down the bank by the hoisting engine. The beginning of the mat was anchored to deadmen on top of the bank about 200 ft. up-stream, and weaving was begun about 100 ft. back on the old mat, so that the full width of the new mat was gotten where the unprotected bank commenced.

In 1908, 4,000 ft. of revetment was put on the north side of the river just above Boonville bridge. At Kingsbury, there is a siding on the west side of main line, and out of the south end of this track the spur was built to the river; this required a main track 6,500 ft. in length, and a spur track 900 ft. in length. Track was laid about 6 to 20 ft. from top of bank all along where revetment was to go in, so that rock could be unloaded and used with as little handling as possible. The bank was first graded to a slope of $2\frac{1}{2}$ to 1 by teams; the mat was then woven and sunk, and the slope paved from bottom up. It is the description of this last section that will be given, as the only differences between this and other works are those mentioned.

The bank was about 18 ft. higher than what was taken as the average low water; the soil is mostly a very fine sand and very little gumbo; the bank was clear of timber and brush, but there were several large snags where the mat was to lie that were taken out by sawing, blowing-out and using teams and line.

Shovelers first dug along the top of the bank and shoveled down all the perpendicular and overhanging points, so as to make it safe for a mule to walk along close to the edge; then a two-mule team plowed two or three furrows as close to the edge of the bank as team could be gotten. The mules were then hitched to a "go-devil," constructed of two 3 x 10-in. plank 3 ft. long, fastened together at the front end and flared to about 4 ft. at the back end; it required one man to drive the mules and one man to weight the drag. This was then run along the back side of furrows, and the loose earth shoved toward the river. After the bank began to slope, two or three "slips" (drag scrapers) were put on, and the bank brought to the desired slope.

It will be seen that only about half of the material in slope is moved, as the excavation makes the fill and does not wash away, as it does when grading by hydraulica. It was found that with this material the filled portion was as solid as the natural surface. Grading was never carried further than 200 ft. in advance of weaving, as the barges from which the mat was being woven would protect the bank from the current for this distance.

The mat was woven 60 ft. wide with a selvage edge on the out-stream side, and sunk parallel with the shore with the inner edge about 3 ft. above the average low water. The mat was strengthened with five double rows of $\frac{3}{8}$ -in. galvanized steel cable—7 strands of No. 11 wire—laid longitudinally one above and one below, and anchored with a double row of similar cable laid transversely every 15 ft. and fastened to deadmen, buried 3 ft. deep and located 15 ft. back from the upper edge of slope. At every intersection of the longitudinal with the transverse rows, the four cables are fastened together with a $\frac{3}{8}$ -in. U clip. The transverse rows are fastened to deadmen by wrapping one cable around the deadman twice and then fastening it to the other cable with two $\frac{3}{8}$ -in. U. clip. The deadmen are pile butts about 3 ft. long, and the object in fastening the cable to them, as mentioned, is to allow the cables to slip when loaded, so that the same strain will be on both the under and upper cables. The willows were cut from bank of river about one mile above the mat, and were hauled by wagons, hauling about 1.6 cords to the load. The road was bad at times, and it required a snap team to pull out of the mudholes, but most of the time the road was in good shape. It required 0.6 cord of brush to 100 sq. ft. of mat; average thickness of mat, about 18 ins.

Weaving was started at a point at the upper end and gradually widened out to full width, anchors being placed for longitudinal cables in the top of the bank about 100 ft. above the upper end. The mat was woven with four small bays fastened together, so as to make the desired width. Fingers of skids were built on barges out of 3 x 12-in. plank, 24 ft. long, and spaced 5 ft. apart, extending from the water level on up-stream side to an elevation of 3 ft. above floor of barge at a point about 3 ft. back from down-stream side. Spools of cable were set under the down-stream ends of the fingers at the proper position for the under longitudinal cables, so

that cable would unwind as the barge was let down stream. The barge was anchored at the shore end to the track, and at the upper end to the mat that had been woven. The mat was woven on the barge as high as the fingers would permit, and cable and clip men would pull the under cables through the mat by means of an iron hook about 2 ft. long, and the top longitudinal cables were run under these, and all were fastened together with a $\frac{5}{8}$ -in. clamp. The barge was then pulled from under the mat with a team, and anchor ropes slacked just enough so that about 2 ft. of mat would be left on fingers. Top longitudinal cables were cut off of reel on shore in lengths of about 100 ft. and spliced together with a square knot on mat as the work proceeded.

The mat was sunk and held down with stone weighing from 20 to 50 lbs., an average of 1.5 cu. yds. of stone being used per 100 sq. ft. of mat. Rock for sinking was unloaded from cars onto shoulder of slope and wheeled in wheelbarrows out onto the barge, anchored lengthwise across the mat, and dumped along the edge of barge. The mat was sunk from the shore side out, so that it would settle away from shore and the transverse cables would tighten up. Sinking was kept at least 100 ft. back from weaving barge to prevent pulling the mat off of barge. When the water was higher than the proper elevation for the shore side of mat, it was sparred out, so that in sinking it would settle to its proper position.

The rock for paving the slope was unloaded from cars onto slope and rolled down to the bottom, where paving was begun. Paving is 10 ins. thick, and was paved from the bottom up, care being taken to fill all the cracks with small stone. At the upper edge of paving, spawls were piled so as to keep the surface water from washing under the paving and starting it to roll. As long as the water was low, a good connection was gotten between paving and mat, but there were parts of this work that were paved during high water, and the rock slid in afterward, making repairs necessary. The work done on the first section in 1897 is in very good shape to-day. The mat has rotted where it has been exposed to the air, but the paving is in good condition.

There have been some slides on the work done in 1906. At these places it was found that the rock was settling under the edge of the mat. These were places where the bank had washed after mat had been put in, and the mat does not lie up on the bank as it should.

Considerable trouble has been experienced on account of the eddy caused by the end of revetment. At Boonville bridge, the revetment ends at an old rock dike, and no difficulty is expected at that point, but at all of the other places it has given trouble. At the end of the work done in 1906 it is probably more noticeable. The revetment at this place was ended at a place where the bank extended out into the river 400 or 500 ft., and now the bank is 100 ft. further in than the revetment, and the revetment has been repaired

twice on account of the river washing behind the end, and allowing the rock to fall in.

The cost of the Boonville revetment (4,000 lin. ft.) is as follows: Cost per linear foot for 60-ft. mat; banks 18 ft. above low water; laborers paid \$1.50 per day; foreman, \$4, and teams, \$3.50. This does not include interest on investment or make allowances for rainy days and moving, but is the actual cost. The contractor's profit is included in the track work only:

	Per lin. ft.
Grading bank, per lin. ft.....	\$0.130
Weaving mat	0.410
Sinking mat	0.110
Paving slope	0.230
Willows, including cutting, hauling and unloading, and price paid landowner.....	0.340
Rock, at \$0.75, delivered on site (2.3 cu. yds. to the lin. ft.).....	1.730
Unloading rock	0.120
Spotting cars with teams.....	0.004
Hauling deadmen and cable.....	0.018
Taking out snags.....	0.020
Cable and clips:	
1,260— $\frac{3}{4}$ -in. clips, at .04.....	\$ 75.60
746— $\frac{1}{2}$ -in. clips, at .035.....	26.16

	<hr/>
Total per lin. ft.....	\$4.671

Excluding the cost of grading the bank and the cost of the rock used in paving the bank (but including the rock used in ballasting the mattress), the cost of the mattress was as follows per square of 100 sq. ft.:

	Per square.
Willows, 0.6 cord.....	\$0.57
Weaving mat	0.68
Sinking mat	0.18
Rock for ballast, $1\frac{1}{2}$ cu. yd., at \$0.75.....	1.12
Unloading rock, $1\frac{1}{2}$ cu. yd., at \$0.05.....	0.08
Spotting cars with team.....	0.03
Hauling deadmen and cable....	0.03
Taking out snags.....	0.05
Cable and clips.....	0.50
Deadmen	0.06
	<hr/>
Total	\$3.31
Tracks, bridge and spur, per $1\frac{1}{2}$ cu. yd. rock.....	0.80
	<hr/>
Total	\$4.11

The last item (tracks, bridge and spur) has been prorated to stone used on the mattress.

The slope wall on the bank required 1.4 cu. yds. per lin. ft., being 10 ins. thick and measuring 45 wide along the slope. The rock cost \$0.75 per cu. yd. delivered on cars, \$0.05 for unloading, and \$0.16 for delivering and laying it on the slope, or a total of \$0.96 per cu. yd., not including the cost of the item of tracks, bridge and spur, which amounted to \$0.53 per cu. yd. of rock, there being 2,200 cu. yds. of rock in the slope wall and on the mattress. Adding this \$0.53 we have a total of \$1.49 per cu. yd. of slope wall, or 41½ cts. per sq. yd. 10 ins. thick.

It will be noted that the labor on the 7,500 lin. ft. of track cost as follows per lin. ft.:

	Per lin. ft.
Grading	\$0.21
Laying track	0.20
Taking up track.....	0.14
Total	\$0.55

Cost of Brush Mattresses and Dikes.*—The following data relate to levee protection work at the West Pass Levee, in Mississippi. The work was done in 1904 by Government forces, and consisted of the construction at the up-stream end of the levee of a paving covering the sloping end of the embankment and the side slopes for a distance of 100 ft. back from the end of the levee crown, together with a paving 80 ft. wide on the natural ground surface laid continuous with the paving on the slopes. The work also included the construction of paving on the down-stream end of the levee slope, beginning 100 ft. back from end of crown on lake side, extending around the sloping end, and continuing along the river slope for a distance of 555 ft., the ground surface adjacent to the paved slopes being covered with a mattress 85 ft. wide, built continuous with the paving. On the up-stream end the paving consisted of riprap laid close by hand with the larger voids clinched with spalls, except for the sloping end and the adjacent pavement, where the riprap was laid on a 3-in. layer of spalls. Around the outer edge of the paving was a trench 2½ ft. deep filled with selected heavy riprap. The paving on the downstream end was similar to that described above, but was somewhat lighter. The riprap was laid on spalls around the sloping edges, but on the earth slopes for the remaining portions. Rock for the paving on the up-stream end had been unloaded on the river bank, 1,200 ft. from the end up the levee. A portion of the rock, however, were obtained from some temporary work done the year previous. The rock for paving and ballast at the down-stream end of the levee had been unloaded at a point about 700 ft. from the work, during the preceding high water.

The mattress consisted of an upper and lower pole grillage with two layers of brush between, the grillage systems being connected

*Engineering-Contracting, March 29, 1907.

by wires passing through the brush, and carried about 35 lbs. of riprap ballast to the square foot. In addition, to prevent a concentrated flow through a borrow pit in the river side, the pit was crossed by a series of pile and brush dikes having their crests on a level with the natural ground surface adjacent. The dikes were anchored to planks buried to a depth of 2½ ft. and resting on crossheads nailed to piles, which were set 6 ft. in the ground with post-hole diggers. Scour underneath the brush filling of the dikes was prevented by ballasted foot mats around the poles.

Brush for the mattress was cut at a point about four miles from the work, and was hauled by teams to the canal bank, whence it was towed by a snagboat to the levee. This barge was also used for quarters for the cutting party. Piles for the dike were obtained in a willow flat about 7,000 ft. from the work. Brush filling for the dikes was obtained from the same willow flat, 80 cords being cut from the ground adjacent to the work and 100 cords from a point about 4,000 ft. north.

The work was greatly handicapped by scarcity of labor, and, in addition, being low water while the towing was in progress, the flat fore shore of the willow flat held the barge some distance from the water's edge, necessitating a long carry and making this feature of the work slow and expensive. The lack of a proper number of barges, and of labor to load and unload them promptly, rendered it impracticable to keep the snagboat steadily employed in towing, though it was necessary to keep her constantly in commission. This still further increased the cost of brush and poles delivered at the mat.

Part of the men employed in the work were paid \$1.25 per 8-hr. day, and part were subsisted laborers, receiving \$30 per month and rations; this latter amounted to 32½ cts. per day, including the cook's and waiter's wages. Subsisted labor was principally used in cutting the brush for the mattress, and in loading and unloading it from wagons. About half of the loading and unloading of the barges was also done by subsisted labor. Teams including driver and wagons were secured at \$3.90 per 8-hr. day for hauling at the place where the mattress brush was cut. For hauling at the down-stream end of the levee, \$3.50 per day was paid for teams. Rock cost \$2.18 per ton (.862 cu. yd.) delivered on river bank. The hauling for the paving at the up-stream end of the levee was done by contract at 50 cts. per ton (58 cts. per cu. yd.) and 33½ cts. per ton (39 cts. per cu. yd.), for the long and short hauls.

The cost of stone paving at the up-stream end of the levee was as follows per square of 100 sq. ft.:

	Total.	Per square.
Superintendence	\$ 40	\$ 0.096
Labor, 163 days, at \$1.25.....	204	0.492
Hauling, 219 cu. yds. rock, 3,700 ft., at \$0.58..	127	0.307
Hauling, 1,566 cu. yds. rock, 1,200 ft., at \$0.39..	605	1.461
Rock, 1,785 cu. yds., at \$3.53.....	4,519	10.916
Total, 414 squares.....	\$5,495	\$13.271

The following is the cost of stone paving at the down-stream end of the levee for 694 squares:

	Total.	Per square.
Superintendence	\$ 146	\$0.21
Labor, 320 days, at \$1.25.....	400	0.576
Hauling, 2,157 cu. yds., at \$0.23.....	487	0.720
Rock, 2,157 cu. yds., at \$2.53.....	5,461	7.868
Total, 694 squares.....	\$6,494	\$9.356

The cost of constructing the brush mattress at the down-stream end of the levee was as given below for 1,162 squares:

	Total.	Per square.
Superintendence	\$ 182	\$0.156
707 days, at \$1.25.....	877	0.754
108 days, at \$1.00.....	108	0.092

Poles, at mattress, 2,560, at \$0.20.....	502	0.423
Wire, 1,100 lbs., at \$0.023.....	26	0.022
Nails, 600 lbs., at \$0.021.....	12	0.011
Staples, 260 lbs., at \$0.022.....	8	0.007
Total, 1,162 squares.....	\$9,535	\$8.203

In addition a small scraper force was employed for five days in smoothing the portion of the borrow pit to be matted and in sloping off the bank between the pit and levee berm. Stumps left in the pit were grubbed out. The total cost of this grading and grubbing was \$198 or \$0.17 per mattress square.

The cost of the 1,414 lin. ft. of brush dikes is shown in the following tabulation:

	Total.	Per lin. ft.
Superintendence	\$ 36.00	\$0.025
Labor building dikes:		
73.1 days, at \$1.25.....	91.40	0.065
46 1/6 days, at \$1.00.....	46.60	0.033
Subsistence, 46 1/6 days.....	15.00	0.010
Piles, 480, at \$0.07.....	33.00	0.023
Brush, 30 cords, 600 ft. haul, at \$0.76.....	61.00	0.043
Brush, 10 cords, 4,000 ft. haul, at \$0.98.....	98.00	0.069
Lumber, 6% M ft. B. M., at \$2.86.....	82.00	0.058
Nails, 175 lbs., at \$0.021.....	4.00	0.003
Total, 1,414 lin. ft.....	\$467.00	\$0.336

The approximate distribution of cost of the brush and poles used in mattress construction was as follows:

	Brush, per cord.	Poles, per pole.
Cutting privilege	\$0.92
Cutting	0.25	\$0.02
Labor, loading and unloading, haul to bank.....	0.11	0.01
Team hire	0.28	0.02
Loading and unloading barges.....	0.68	0.06
Towing	0.44	0.03
Labor, loading and unloading, haul bank to mattress.....	0.12	0.01
Team hire	0.19	0.01
Superintendence	0.18	0.01
Subsistence	0.34	0.02
Total	\$2.61	\$0.20

The distribution of cost of hauling the rock used in mattress construction was as shown below:

	Per cu. yd.
Labor, loading and unloading wagons.....	\$0.07
Team hire	0.14
Superintendence	0.02
Total	\$0.23

Cost of Clearing Land.—The cost of clearing the margins of Indian Lake, N. Y., for 35 miles, was about \$12 per acre for 1,160 acres. Men were paid \$1 a day and board; and the board cost about 50 cts. a day. Foremen (1 foreman to 20 men) were paid \$35 a month and board. Each acre, it was estimated, ran from 50 to 75 cords of wood. Each laborer averaged one-fifth acre cut per day, including some piling, but no burning of the timber; so that the cutting cost \$7.50 per acre. There was no large merchantable timber, all having been cut down years before. The growth was mostly small pines, balsams and various hardwoods.

In the work for the filter beds at Brockton, Mass., 1894, there were 18.8 acres cleared and grubbed, of which 14.4 acres were standing pine. The trees varied from 6 to 24 ins. in diameter; and there were about 3 trees per sq. rod, or 480 per acre. When cut up, about 35 cords of wood per acre were obtained. The total cost of pulling and disposing of stumps was \$112 per acre, or 23 cts. per tree. Wages of laborers were \$1.50 a day.

A very common price for clearing and grubbing forest land in the eastern part of America is \$50 an acre, when wages are \$1.50 a day.

For contract prices see the section on Railways. Consult the index under "Clearing."

Design of Stump Pullers.—The following is a very brief abstract of two articles on grubbing stumps in *Engineering-Contracting*, March 25 and April 8, 1908. Several different types of stump pullers are illustrated in detail and their use described, but I give here only two, which are not so well known, but which I have made and used with success.

A style of stump puller, known as the sweep stump puller, is shown in Fig. 7. Its operation is simple yet very effective. One end of the sweep *S* rests on the ground, and the other end is mounted on a wagon wheel. The sweep is an 8x10-in. timber 24 ft. long, and at the free end, *B*, there is attached a single or double whiffletree, as described. The arrangement at the fixed end, *A*, is somewhat more complex and may well be described in detail. About 3 ft. from the end is an eyebolt, *I*, to which is fastened an anchoring chain attached to a convenient stump or "dead man," *P*. On each side of the eyebolt, and almost 4 ins. from it are attached hookbolts, *A*₁ and *A*₂, and still further away two similar bolts, *A*₃, *A*₄. The stump pulling wire cable is fastened to a short chain, *K*, and then carried over on *A* from *F* and attached to a pile or stump as shown. The chain *K* is hooked to the bolt *A*₁.

In operating it the lever is drawn in the direction of the arrow,

causing a strain on the pulling cable. The horse is driven ahead until the sweep has the position shown by the dotted lines, and when this position has been reached a short length of chain indicated by the dotted line *K* is hooked at one end to the pulling chain and at the other end to the hook bolt *K*₂. The horse is then turned and driven in the opposite direction, putting a further strain on the pulling chain and slackening the chain *K* so that it can be shortened and hooked up again when the horse has moved the sweep to

Fig. 7.—Stump Puller.

the position shown by the left hand set of dotted lines. The horse is then started on its forward trip, then back again, and so on, pulling alternately on chains *K* and *K*₁ and putting, ultimately, an enormous strain on the stump or pile.

An idea of the power exerted is gained from the following brief calculation. If the distance between the king bolt of the whiffle-tree and the bolt *I* is 20 ft., and if *K*₁ and *K*₂ are 4 ins. ($\frac{1}{3}$ ft.) from *I*, the pull of the horse is multiplied $3 \times 20 = 60$ times. A horse capable of pulling 500 lbs. would then put a strain of $500 \times 60 = 30,000$ lbs. on the chain *K* and *K*₁. Then in the triangle *abc*, *ab* represents 30,000 lbs. and *ac* represents the pull on the stump, which must always be greater than 30,000 lbs. to an amount depending upon the inclination of the *A* frame; if the batter of the *A* frame is 1 in 2 the pull on the stump will be 40,000 lbs. As a matter of fact, one horse cannot maintain a 500-lb. pull, and a team must be used where such a pull is necessary.

Very large stumps can be pulled with this simple device and a team of horses.

From the figures given it is evident that heavy chains and cables must be used or else there will be frequent breaks.

One set up of the machine can be used to pull a large number of stumps or piles, since it is necessary to move only the comparatively light A frame. With a long cable, to give a good reach to the machine, there should be used take ups, else considerable time is consumed in taking up the slack of the cable. The crew to operate this style of machine consists of a foreman, three laborers and one team, the cost varying from \$10 to \$15 per day. This machine and the one shown in Fig. 8 were both used by one of the editors of this journal for pulling piles, the machines being adapted for either pile or stump pulling.

Fig. 8.—Stump Puller.

The legs of the tripod shown in Fig. 8 were 8 x 8-in. timbers, 10 ft. long. The rope is reeved through a set of triple blocks and carried to the 4-in. chain. The speed wheel and pinion are respectively 20 ins. and 4 ins. in diameter. This arrangement gives a powerful strain on the chain or cable fastened to the stump. The stumps can be pulled by hand power or horses, or a line can be run from the 12-in. drum to a small hoisting engine and the machine operated by it. This whole outfit, though, must be moved for each stump that is to be pulled.

For the cost of this tripod machine and the cost of pulling piles with it, see page 1017.

Cost of Removing Stumps in Clearing Land.*—Removing stumps by hand is a slow and costly method when the stumps are of small size and is out of the question for the large stumps of fir and other

**Engineering-Contracting*, Dec. 22, 1909.

trees up to 5 and 6 ft. in diameter. In the last condition the principal up-to-date methods are burning, blasting and pulling or some combination of these. Burning is considered the best way to remove pine stumps which have a large amount of turpentine, as this greatly assists in the process, and the long, deep roots of these trees are a great hindrance in pulling. In regard to burning these stumps Mr. Ferris, of the Mississippi Station, says:

"The common method * * * is to dig a hole about 12 ins. deep with spade or post-hole digger on one side of the stump, as

Fig. 9.—Machine for Boring Stumps.

close to it as possible, and to use this as a furnace for firing the stump. In digging these holes it is necessary that the dirt be removed from as much of the surface of the stump as possible, so as to allow the fire to come in direct contact with the side of the stump for at least 6 ins. An ordinary turpentine dipper on a suitable handle makes one of the best implements for removing this dirt."

This is a rather slow process, but may be greatly hastened by boring a slanting hole through the stump from the opposite side to the fire hole. For boring, the Mississippi Station has used the

simple machine shown in Fig. 9, invented by J. W. Day. It is thus described:

"A 2-in. ship auger is welded onto one end of a $\frac{3}{4}$ -in. iron rod 6 ft. long. Four inches from the other end of this rod a collar is welded and the end of the rod passed through an iron box fastened to a movable frame about 18 ins. square. A bevel gear is then fastened to the extreme end of this rod either by a key or set screw and works into a second gear of the same kind fastened on a horizontal shaft. This horizontal crank shaft is made of 1-in. iron rod bent at one end to form a handle, with a fly wheel fastened on the opposite end. It works through two boxes fastened to the movable frame and slides down the main frame as the auger bores into the stump. The upper end of the machine is elevated about 5 ft. and stands on two cart wheels, on which it is easily rolled from stump to stump or from field to field by a single indi-

WOOD
MEN

Fig. 10.—Blast Holes in Stump.

vidual. This elevation of the frame helps to brace it against the stump in boring, raises the crank shaft to a height at which it can be most easily turned, causes a slight pressure to be constantly exerted against the auger, and makes it possible to bore the hole diagonally into the stump. At the extreme upper end of the frame is a small windlass with ropes attached which is used for pulling the auger out of the stump."

This machine was used to aid in clearing 2.8 acres of land which had been cut over about seven years before. The sapwood had decayed, but the balance of the stump above ground and all below was sound. On this plat there were 158 stumps that required boring. These averaged 13.6 ins. in diameter, and the length of hole bored averaged 19.7 ins., the total cost being less than \$8 an acre, figuring labor at \$1.50 per day.

For burning the large stumps of fir, etc., in the Pacific Northwest, a quicker method is used, which consists of boring two intersecting holes, as in Fig. 10, and burning by starting a fire at the inter-

section with the aid of redhot coals or a piece of iron heated to a white heat. After the part marked *A* is burned out the fire is maintained by filling the space with bark and litter. While the method first described generally results in burning the stump low enough to allow of cultivating over it in the case of pine stumps, the method used on the western trees leaves the larger stringers with their smaller roots to be pulled out by steam or puller, or "they may be entirely burned by digging away the earth and rolling a small log alongside of the root."

Other methods of burning are to split the stump with a small charge of powder and then kindle a fire in the hole thus made, and charcoaling or pitting. The latter, which consists essentially of keeping a smoldering fire around the base of the stump, is reported to be very economical for large stumps. Mr. Ferris says "removing stumps by this method [boring and burning] has been decidedly cheaper than by any other method tried, as it requires only a small expenditure for machinery, practically no repair bills, and can be operated by a single individual."

It is stated that in the section reported on by Mr. Thompson scarcely anyone undertakes to clear even a small tract without the use of powder. Powder is also used on the pine stumps of Mississippi, the common method being to bore a 1½-in. hole from the surface of the ground diagonally downward for 10 to 20 ins. and to insert in this from ¼ to 1 lb. of dynamite. This amount will shatter the general run of pine stumps, and makes the cost of this part of the work from 5 to 20 cts. per stump. With stumps of the fir type, which do not usually root deeply, blasting is best done by placing several sticks of dynamite beneath the center on the hardpan, if not too deep, so as to cause the force of the explosion to be exerted upward. Mr. Thompson gives the following data as to size of charge under ordinary ground conditions, for shattering large stumps which are to be removed by stump pullers, blocks or teams:

Diam. of stump, ins.....	18	24	30	36	48	60	72
Sticks of powder.....	5	7	10	20	35	50	65

The sticks are 1½ x 8 ins., weigh a little over ¾ lb. and cost from 10 cts. to 15 cts. a pound. The average cost of the removal of each stump from a tract of 120 acres containing fir stumps from 1 to 4 ft. in diameter was reported as follows:

	Cents.
Powder	49.76
Fuse	2.37
Caps	0.87
Labor	30.66
Total	83.66

If dynamite is handled with ordinary care there is but little danger attached to its use except in cold weather, when it should be kept warm, preferably at about 70° F.

After loosening and shattering stumps by blasting, it is necessary to gather them in a pile for burning. This is usually done by means of a capstan or a donkey engine. The latter is reported to have found quite general application in the Northwest. A gin pole

is set up, as shown in Fig. 11, and the stumps drawn to it. When handled to advantage this method is considered to be time-saving and cheaper than hand methods. Another type of puller is the vertical derrick, which has the advantage of applying the pull in the best direction for stumps having long tap roots, but it is objected to on account of having to be moved for each stump.

Cost of Clearing and Grubbing, Ohio.*—Mr. Julian Griggs gives the following: All trees and brush on a reservoir site, near Columbus, Ohio, were cleared and grubbed by contract in 1904-5. The work was begun June 14, 1904, and carried on continuously till Aug. 5, 1905, the season being unusually favorable. The area cleared was 255½ acres, lying in a narrow river bottom 5.8 miles long. It was thickly covered with shrubs and trees—elm, locust oak, hickory, sycamore, etc. There was a rank growth of weeds, horse-cane predominating. All was grubbed except about 5 acres.

A trimming gang first cleared and grubbed the brush, cut off

Fig. 11.—Method of Pulling and Handling Stumps.

all low limbs and all small trees, and piled the stuff ready to burn. They were followed by a pulling gang of 6 to 12 men, a team of horses and a stump puller. During the winter it was possible to burn everything as fast as cleared.

A "Hawkeye Stump Puller" was used. (This type of stump puller is illustrated and its use described in detail in *Engineering-Contracting*, March 25, 1908.) It consists of a capstan or vertical windlass (operated by a team of horses) that is mounted on a bed of two oak timbers (10 x 10-in. x 16-ft.) framed to form a cross. The drum is 2 ft. high and 13 ins. diam. The sweep (8 x 8-in.) to which the horses are fastened is 20 ft. long. Dragging from the sweep, directly back of the horses, is a stick, the end on the ground being shod with an iron point, the purpose being to take the strain off the horses when they are standing still. Two ¾-in. wire cables, each 100 ft. long, hooks, grips, blocks, snatch cables, etc., compose the rest of the outfit. In operation, the timber bed is buried in the ground, and iron pins driven alongside the timbers into the ground,

**Engineering-Contracting*, Oct. 17, 1906.

or the timbers are loaded with stone. In pulling a tree, the snatch cable is fastened around it about 15 or 20 ft. above the ground. The cable is usually passed through a snatch block fastened to a tree near the stump puller, so as to bring the cable to a horizontal position as it winds around the drum. If the tree does not yield at first, some of the roots are cut, or a dynamite charge is exploded among the roots while the strain is kept on the cable. Stumps, of which there were many, were much harder to pull than trees, and most of them were dynamited and taken out in pieces.

The following was the cost of clearing and grubbing 255½ acres:

	Per acre.	Per cent.
Superintendent, at \$4.17.....	\$ 4.16	2.6
Timekeeper, at \$1.75.....	1.76	1.1
Foreman, at \$2.50.....	14.72	9.2
Carpenter, at \$2.00.....	0.48	0.3
Dynamite men, at \$1.75.....	3.04	1.9
Laborers, at \$1.50.....	35.28	53.3
Single horse, at \$1.50.....	1.28	0.8
Two-horse team, at \$3.50.....	11.68	7.3
Total labor	\$122.40	76.5
Dynamite, at 11½ cts. per lb.....	30.56	19.1
Machinery and repairs.....	7.04	4.4
Grand total	\$160.00	100.0

The work required 255 days, or an acre per day, with an average force of:

- 1 superintendent.
- 1 timekeeper.
- 5 foremen.
- 1/5 carpenter.
- 1½ dynamite men.
- 65 laborers.
- 1 horse.
- 3½ two-horse teams.

There were 266 lbs. of dynamite used per acre.

Before the reservoir could be filled with water it had grown up with weeds, which it cost \$7 more per acre to cut and burn. This was one summer's growth.

Cost of Blasting 3,500 Stumps.*—The Long Island R. R. bought a tract of land, in 1905, in Suffolk county on Long Island, in order to carry on experimental agricultural work. The tract was situated in the waste lands of the island and the first work to be done was to clear it of timber. A force of men was put to work cutting down the trees and undergrowth, and this work was followed by the stump blasting.

The blasting crew consisted of two men only, except for the three last days of the work when a third man was employed to hasten the finishing of the job. The work was done during the latter part of the summer and the fall of the year, good weather prevailing most of the time.

**Engineering-Contracting*, May 12, 1908.

One man employed was accustomed to handling explosives and had experience in blasting stumps. He was paid \$2.50 for a 10-hr. day. The second man was a common laborer and was paid \$1.50 per day. The third man, used for three days, also had handled explosives. He was paid \$3 per day.

In all 10 acres of land were cleared. The blasting gang made the hole under the stump and charged it, setting off the charge, but the work of cleaning up after the blast was done by other men. The stumps were mainly white oak and chestnut, varying in size from 18 ins. to 7½ ft. in diameter. Many of the stumps ran from 4 to 4½ ft. in diameter. Each acre of ground was measured off and a careful record kept of the number of stumps blown on each acre.

The following table shows the number of stumps blasted and the amount of dynamite used:

Acre No.	Number Stumps.	Lbs. dynamite used per acre.	Lbs. dynamite per stump.
1	293	145½	0.50
2	310	152	0.49
3	301	159½	0.53
4	270	150½	0.56
5	280	211½	0.75
6	305	191½	0.62
7	285	178	0.62
8	337	188½	0.56
9	334	198½	0.59
10	797	446	0.56
Total	3,512	2,031	0.59

The soil was a light loam with sand or gravel underlying it. Naturally the amounts of dynamite used per stump varied with the size of the stump. Small stumps up to 4 ft. in diameter needed ½ lb. of dynamite. Stumps from 4 to 5 ft. in diameter needed from 1 to 3 lbs., while the largest stumps, measuring from 6 to 8 ft. in diameter needed from 3 to 4 lbs. of dynamite. The largest stump blown was a chestnut 7½ ft. in diameter which took 3½ lbs. dynamite. It will be noticed that the average per stump was not quite 0.6 lb. All the dynamite used was 40%.

In blasting the stumps the helper made a hole with an auger or bar under the stump, so the charge would be close up to the stump and near the center. The dynamiter prepared a large number of cartridges with fuse and caps in them in advance, so that when a number of holes had been made, all he had to do was to place the charge and tamp up the hole. Double tape fuse was used to put off the blast. The fuse was cut to lengths to explode the load within a given number of seconds, just enough time being allowed for a man to run to a safe distance. For most of the stumps, fuse a foot and a half in length was used, and when the end was split to allow of easy lighting, it took 30 seconds for this fuse to burn to the charge, hence this was known as a "30-second length." Care was taken to use enough dynamite to blow out the entire stump, but not to waste the explosives. Small stumps were blown out

whole, but the larger ones were split up by the blast so they could be easily handled.

The number of stumps blasted per day varied somewhat, according to the size of the stumps and the difficulties encountered. The best day's work for two men was 110 stumps, while on other days they did 97, 60, and 99, the average being 84 for two men, for the job. On one day that three men worked 160 stumps were blasted. In clearing an adjoining piece of land 1 man by himself blasted in 1 day 100 stumps, but he had prepared the charges the day previous. The cost of blasting the stumps for the 10 acres was:

	Total	Per acre.
1 man, 40 days, at \$3.50.....	\$140.00	\$14.00
1 man, 40 days, at \$1.50.....	60.00	6.00
1 man, 3 days, at \$3.00.....	9.00	0.90
2,031 lbs. 40% dynamite, at 15 cts.....	304.65	30.46
2,600 caps, at 75 cts. per 100.....	27.00	2.70
7,000 ft. D. T. fuse, at 45 cts. per 100..	31.50	3.15
Total	\$572.15	\$57.21
This gives a cost per stump of the following:		
Labor		\$0.059
Dynamite		0.086
Caps		0.008
Fuse		0.009
Total		\$0.162

This work was done under the direction of Mr. H. B. Fullerton, special agent of the Long Island R. R. Co., to whom we are indebted for the information.

Cost of Blasting 1,100 Stumps.*—In grubbing stumps from land, one of the most economic methods is by blasting, provided care and judgment are shown in the use of explosives. The tendency seems to be to use a larger amount of explosives than is necessary. Then, too, different kinds of explosives are sometimes used in the same charge, such as dynamite and Judson powder. This should not be done. But one kind of powder should be used in a hole. For small and medium sized stumps dynamite will give the best results, but Judson powder will do efficient work on large stumps, and, at times for very large stumps, black powder is the cheapest to use.

The charge should be placed well up under the stump and as near the center of the stump as possible. A bar is generally the best tool for making the hole. When only one charge is placed under the stump it is more economical to use fuse and a cap. It is possible in stump blasting to use single tape fuse, but, if the ground is very wet, it may misfire. Under such conditions it is better to use double tape fuse. When several charges are placed under one stump, it is always advisable to use electrical exploders, so that the charges will be exploded simultaneously. For a single charge, electrical fuses are too expensive.

In the job, the cost of which we give below, dynamite was used

**Engineering-Contracting*, June 3, 1908.

exclusively, and caps and fuse were used for most stumps, but electrical exploders were used on some, as several charges were placed under some of the largest stumps. There were 1,100 stumps blasted from 4 acres of land, the job being in eastern New Jersey. The trees had been cut about 2 years, and were mostly white oak and hickory. They varied in size from 4 ins. to 6 ft., the average size of the 1,100 stumps being about 15 ins. in diameter.

The dynamite used was 40 per cent. The ground was full of large boulders, and more fuse, single tape, was used than would have been required if the ground had not been full of stones. The long fuse was necessary in order to allow the men time to get away from the flying pieces of stone. Two men only were used. One man handled the dynamite and the other prepared the holes. These men did nothing towards cleaning up the stumps after they were blasted.

The cost of the labor was as follows:

Dynamiter, 19 days, at \$3.50.....	\$ 66.50
Helper, 19 days, at \$1.50.....	28.50
Total	\$ 95.00

The cost of the explosives was:

850 lbs. dynamite, at 15 cts.....	\$127.50
1,300 caps, at 75 cts for 100.....	9.75
1,300 ft. S. T. fuse, at 45 cts per 100.....	5.85
200 short electrical exploders, at 6 cts.....	12.00
Total	\$161.10

The total cost of the 4 acres was \$256.10, giving a cost per acre of \$64.02.

The cost per stump was:

Labor	\$0.086
Dynamite	0.114
Caps	0.009
Fuse	0.005
Exploders	0.016
Total	\$0.232

The average amount of dynamite used per stump was 0.77 lb.

This is a very economical job of blasting, both as to labor, costs and explosives.

We are indebted to Mr. Oscar Klossam, of Halesite, Long Island, N. Y., for these data. The work was done under his direction and according to his methods.

Cost of Clearing and Grubbing by Blasting.*—Mr. Daniel J. Hauer is author of the following:

The work was done in 1893 in the suburb of an Eastern city. Nine acres of closely spaced trees, averaging about 20 ins. diam., were cleared. Trees ranged from 6 to 36 ins. diam. All smaller than 6 ins. was classed as brush. The trees were first cut down, and the brush and leaf wood piled and burned. The trunks were made into saw logs and cord wood. The timber was mostly oak,

**Engineering-Contracting*, Feb. 27, 1907.

hickory and chestnut. Work was done in the spring of the year in good weather.

The tools were: 33 axes, 29 mattocks, 30 shovels, 1 hatchet, 1 hand saw, 3 cross-cut saws, 2 files, 3 water buckets, 2 grindstones, 1 churn drill and 1 auger. These tools cost about \$80, which could be charged at a rate of \$9 per acre to the job.

Foremen were paid \$2.50 per 10-hour day and laborers, mostly Italians, were paid \$1.25. One foreman looked after the chopping and grubbing, consequently his salary is divided between these items, while a second foreman gave his time exclusively to the blasting.

The chopping down of 1,212 trees and the brush took about 12 days, the cost being as follows:

Foremen	\$ 20.00
Laborers	149.61
Total	<u>\$169.61</u>

This makes a cost of \$18.84 per acre. For eight days, as the above work was going on, another crew of men were piling and burning brush and grubbing the small stumps and stumps. This work was done at the following cost:

Foreman	\$ 10.00
Laborers	129.74
Total	<u>\$139.74</u>

Or a cost of \$15.53 per acre, and a total cost per acre for both chopping and cleaning up, of \$34.37. This can be divided as follows:

Foreman	\$ 3.33
Laborers	31.04

When this much of the work was done a foreman and a crew of 4 men began the blasting of stumps.

The following was the cost, 50 stumps per day:

	Per day.	Per stump.
1 foreman at \$2.50.....	\$ 2.50	\$0.050
4 laborers at \$1.25.....	5.00	0.100
200 lin. ft. double tape fuse at 50 cts. per 100 ft.....	1.00	0.020
50 caps at 75 cts. per 100.....	0.40	0.008
52 lbs. 40% dynamite at \$0.15.....	7.80	0.156
108 1/2 lbs. Judson powder at \$0.10.....	10.85	0.217
Total	<u>\$27.55</u>	<u>\$0.551</u>

This work took 25 days, and, as there were 124 stumps per acre on the 9 acres, the cost of blasting stumps was \$73.70 per acre.

Both dynamite and Judson powder were placed in each hole.

The stumps were not so large, except in a few cases, that one charge placed under it, by churning a hole with the drill and auger beneath the stump and then loading it, did not either blow the stump out or shatter it so that the grubbers were able to handle it.

The cost of grubbing the roots after blasting was as follows:

Foreman	\$ 40 00
Laborers	277.36
Total	\$317.36

This makes a cost per acre of \$35.26, or \$0.262 per stump, which makes a total cost of \$0.813 per stump for blasting and grubbing.

The grinding of the axes for chopping cost \$5.87, or 65 cts. per acre, and an allowance of \$9 per acre must be made for tools.

At the same time the blasting began the chopping gang began to cut the tree trunks up into cord wood and saw logs, while the cleaning gang was set to grubbing the roots and the remains of the stumps after the blasters. The saw logs and cord wood were hauled away under another contract.

The making of cord wood took eight days and cost:

Foreman	\$10.00
Laborers	81.25
Total	\$91.25

This was a cost of \$10.14 per acre. Unfortunately the wood was not corded up before being hauled away, so no accurate record was made of the amount, but there were between 175 and 200 cords, indicating a cost of about 50 cts. per cord after the trees were cut down.

From the above we can obtain the total cost of the entire job (9 acres), which was as given below:

	Total.	Per acre.
Chopping	\$ 159.61	\$ 18.84
Grubbing and clearing.....	139.74	15.53
Making cord wood.....	91.25	10.14
Blasting	663.59	73.78
Grubbing after blasting.....	317.36	35.26
Grinding axes.....	5.87	0.65
Tools	81.00	9.00
Total	\$1,468.42	\$163.25

This is not much different from the cost of the work recorded by Mr. Julian Grigg in the following paragraphs.

Cost of Clearing and Grubbing for a Railway.*—One of the items of work to be done in grading a railroad is generally the clearing and grubbing of the land. Under some contracts and specifications this work is paid for as one item, under others as two items as clearing and as grubbing, while under other forms of contracts this work is included in that of excavation.

The method of paying for clearing by the acre as one item and grubbing as another item is to be commended. In order to do the excavation all the land must be cleared, but in addition to the area used for the cuts and embankments, the entire width of the right of way must be cleared, and overhanging trees and branches must be cut away. On the other hand there is no need of grubbing the area occupied by the embankments, nor that on the

**Engineering-Contracting*, Dec. 25, 1907.

right of way not included in the cuts, hence there should be no reason why this area should be included in the payment. Likewise the method of doing the excavation will very materially effect the cost of the grubbing, while it does not play any part in the cost of clearing.

When steam shovels are used the grubbing cost is small, as this machine will undermine the stumps, causing them to fall into the pit, where they can be loaded onto the cars by means of chains, attached to the dipper teeth. This work retards the progress made by the shovel, but the cost of grubbing is greatly reduced, and a contractor could afford to bid a low price on the grubbing when done with a steam shovel, if it is not lumped in with the clearing or other work.

When grubbing is done in connection with rock excavation, its cost is small as the stumps are shot out with the blasting of the rock, and the only additional expense is to dispose of the stump. This will have to be done by hand and will be work that the contractor will charge for under grubbing.

When grubbing is done for scraper work the stumps and largest roots must be blasted and dug out, and the work is much more expensive than with rock excavation and steam shovel work, although a large railroad plow in loosening the ground will cut and break up many of the roots, so that they do not have to be grubbed.

The grubbing for elevating grader excavation must be done much more thoroughly, than that for scraper work. The stumps and large roots must not only be grubbed, but all the small bush stubs and roots must also be cut out. This is necessary as the grader plow will not cut these roots, as the pull on the plow is a steady one, unlike that of a breaking plow, which can be run in jerks, while the plowman can shake up the plow, which is a considerable help. In grubbing for a grader it is not advisable to blast the stumps, as this makes large deep holes, which, after rains, become full of water and soft, thus causing the traction engine and grader to mire in these holes. For this reason where there are many stumps of 6 ins. or more in size a stump puller should be used. The stump puller does its work much better than blasting, as it will not only pull up the stump, but also all the large roots and many of the small ones. Nor does it leave as large a hole as a blast does. Its work is as economical as blasting, and at times is much cheaper. The small stubs and roots must all be grubbed by hand. To do efficient work of grubbing for a grader, after the large stumps have been pulled, men should be spaced a few feet apart and the entire area gone over, the men working in rows grubbing up everything that may effect the working of the grader. This makes grader grubbing more expensive than that of any other grubbing for ordinary excavation work.

The job to be described was the clearing and grubbing on nine miles of railroad construction. Most of the line was through cultivated fields, but in 11 places varying in length from 100 to

4,600 ft. there was clearing to be done. In all there were $14\frac{1}{4}$ acres, of which $1\frac{1}{4}$ acres were over areas upon which embankments were to be made, while 13 acres were in cuts, hence there was both clearing and grubbing to do. The excavation was to be done by an elevating grader, and, as stated above, the grubbing had to be done more thoroughly than it would have been, if other methods of excavating had been employed.

The first work done was to clear the ground. Most of the brush was burned, but some of it and the logs were rolled to the edge of the right of way and piled up. The trees, of the size of 6 ins. or more in diameter, numbered about 40 to the acre; but there was a very rank undergrowth of bushes and saplings, the stumps and roots of which all had to be grubbed. The work was done by contract, and the men working upon the job were not experienced woodsmen or axemen, but were such as could be obtained at the labor market centers. Many of them were foreigners. The wages paid to the foreman was \$2.50 and to the men \$1.50 per ten hour day. A waterboy was paid \$1.00 per day. In the clearing gang an average of 12 men were worked, some using axes and others brush hooks. The brush was piled by hand, no forks being used, and the logs, few being more than 3 ft. in diameter, were cut short and rolled by means of hand sticks. Some few were carried by the men with these sticks.

The cost per acre, there being as stated $14\frac{1}{4}$ acres, was:

	Per acre.
Foreman	\$ 4.59
Men	27.10
Water boy.....	1.36
Total cost clearing per acre.....	\$33.05

The grubbing was done by a gang of men averaging 15. The wages were the same. Some few of the larger stumps were blasted, and their roots afterwards grubbed. Dynamite, costing 15 cts. per lb., was used for this blasting. No separate record of the stumps that were blasted nor of the explosive used for each was kept, only the total cost of the explosives being kept, and the labor of blasting was included in with the other grubbing. About 6 stumps were blasted to the acre.

The cost per acre, there being but 13 acres to grub, was:

	Per acre.
Foreman	\$ 4.54
Men	38.84
Water boy.....	1.81
Explosives	2.54
Total cost grubbing per acre.....	\$47.73

The men used long cutter mattocks and short handled shovels in grubbing the stumps and roots. There is but little doubt that this cost of grubbing could have been reduced by the use of a stump

puller, but the contractor did not own one, and thought the job too small to justify purchasing such a machine.

The total cost for clearing and grubbing was as follows:

	Per acre.
Foreman	\$ 8.74
Men	62.54
Water boy.....	3.00
Explosives	33.00

Total clearing and grubbing per acre.....\$76.60

The tools used for this work cost about \$50, but with the exception of the brush hooks, they were all used on other work, hence to charge half their cost to this job would be sufficient. This means a charge for tools of \$2 per acre, making a total of \$78.60. This work was being done at the same time that grading and other construction was going on, hence the charge to be added for general expense, such as superintendence and office expenses would be small.

This clearing and grubbing was not paid for by the acre, but the work was included with the grading, and the price of excavation covered the clearing and grubbing. There was 90,000 cu. yds. of earth excavation on the 9 miles of road, hence the cost of clearing and grubbing amounted to about 1½ ct. per cu. yd. of earth. If elevating graders had not been used, the cost with the same forces doing the work, would have been less than 1 ct. per cu. yd.

Another example of clearing and grubbing is given below. Five acres of woodland were to be cleared and grubbed of all bushes and worthless saplings, vines and briars. The undergrowth was dense. None of the trees were to be cut. The clearing was done by a contractor, but he was paid "force account," that is by the day plus a percentage for his work. The wages paid were the same as in the example just given. The brush, old logs and other debris had to be burned, and care had to be exercised that none of the trees were injured, as the woods was to be made into a park. The cost of clearing was as follows:

	Per acre.
Foreman	\$ 7.25
Men	54.06
Water boy.....	3.00
Total	\$64.31

This work was done in the fall of the year, and the weather was exceptionally good. The following spring the ground had to be thoroughly grubbed in order to plant grass seed in the woodland. This work was done with mattocks, every inch of the ground being gone over, brier roots, old stumps and all roots of bushes being dug out. There were also a few old stumps that had to be taken out, but the work was mostly the small surface roots of bushes, saplings and briars. After the ground was gone over with mattocks, steel

rakes were used to rake out the roots, and put them in piles. Wheelbarrows were then used to haul them away to a waste pile, where they were afterwards burned, when they had dried sufficiently.

This work had to be well done, or else the grass seed would not make a good sod; that an excellent sod was obtained in one season, was evidence that the work was well done. Company forces did this grubbing, the rates of wages being: Foreman \$2.50 for 9 hours, and laborers \$1.50 for 9 hours. The cost of the grubbing was:

	Per acre.
Foreman	\$ 4.26
Men	51.30
Total	\$55.50

This gives us a total cost for clearing and grubbing of \$119.81 per acre. To this should be added \$2.00 per acre for tools.

If this work had been done by contract, it could not have been done better, but there is little doubt, that the cost would have been less.

Cost of Transporting Logs by Driving and by Trains.*—Practically one-third of the lumber used for pulp and paper in the state of Maine comes down the Kennebec waters. The annual drive in the main river usually amounts to about 150,000,000 ft. B. M. In Water Supply and Irrigation Paper No. 198, Mr. H. K. Barrows gives some data as to the cost of driving on the above waters, the data being compiled from the reports of the Kennebec Log Driving Co., which controls the drives in the main river, the Moose River Driving Co. and the Dead River Driving Co. These companies drive the logs and apportion the cost as a tax per M. ft., this tax varying with the distance; this tax is the cost per M. ft. for logs driven the distance for which the full tax applies. In the table below the cost of log driving on Kennebec River and tributaries, 1901-1905, is given, the cost per ton mile being approximate and calculated on the basis that 1,000 ft. B. M. weighs 3,500 lbs.:

Drive.	Distance. Miles.	Average tax per M. ft.	—Cost of driving— Per mile. Thousand.	Per ton. Mile.
Kennebec river.....	91	\$0.41	\$0.0045	\$0.0026
Kennebec river.....	24	.12	.0050	.0028
Dead river.....	43	.38	.0039	.0051
Moose river.....	17024	.014
Moosehead lake (Moose river to lake outlet, logs towed by boat)	9	†.12	.013	.0074

The figures cover, in addition to the cost of driving itself, the

**Engineering-Contracting*, Nov. 13, 1907.

†Contract price for 10 years.

other charges arising in carrying on this work, such as costs of dams, improvement of channel, booms, etc., as well as executive charges. Many important changes have been made during the period covered by the above costs and consequently the unit costs are higher than they would have been had a longer series of years been considered. From the above table it appears that the cost of log driving per ton mile varies from about one-fourth to $1\frac{1}{2}$ cts., depending on the distance driven and difficulties experienced. The average freight rate in the United States at present is about 0.8 ct. per ton mile and for the New England group of railroads 1.20 cts. per ton mile. Under exceptionally favorable circumstances rates as low as 0.2 ct. per ton mile have been granted for coal transportation from the coal fields to tide water. For the sake of comparison rates during 1906 for log transportation on the new Somerset Ry. extension are given below:

Logs shipped from Moscow to.	Average distance, miles.	Charge per ft. B. M.	Cost of transportation.	
			Per mile. Thousand.	Per ton. Mile.
Bingham	12	\$1.75	\$0.146	\$0.030
Solon	20	2.00	.100	.057
North Anson.....	29	*1.50	.052	.030

*This price involves reshipment as manufactured lumber on Somerset Railway.

Cost of Cordwood and Cost of a Wire Rope Tramway.—Mr. B. McIntire gives the following about a wire ropeway built by him in 1884 in Mexico. He states that when the inclination of an endless traveling ropeway is greater than about 1 in 7 it will run by gravity, the speed being controlled by a brake. A ropeway running 200 ft. per min. with buckets at intervals of 48 ft., each carrying 160 lbs., will deliver 20 tons per hr. By using two clips close together on the rope, loads of 700 lbs. per bucket may be carried. This particular ropeway was used for carrying cordwood to a mine. Its total length was 10,115 ft. between terminals, and the difference in elevation was 3,575 ft. The longest span between towers was 1,935 ft., the shortest, 104 ft.; there were 10 towers and two terminals. Hewed timbers were used for the towers, being much better than round timbers in maintenance. The rope was $1\frac{3}{16}$ -in. diam., plow steel, of 300,000 lbs. strength per sq. in., bought of the California Wire Works. It was transported on 7 mules in lengths of 2,250 ft., each mule carrying a coil 321 ft. long, with a piece 10 ft. long between mules. The coils were 24 in. diam. There were 3 men required to every 7 mules. Care must be taken to lead the mules on a steep ascent to prevent a sudden rush that may throw a mule over a precipice. The ropeway, after erection, was lubricated best by using black West Virginia oil (instead of tar), applied continuously at the rate of a drop a minute. This was vastly better than intermittent oiling.

The cost of this ropeway was as follows:

Upper terminal.....	\$ 192.45
Lower terminal.....	218.00
5 trees fitted for towers.....	103.00
5 towers	854.25
Counterweight tower.....	169.00
Remodeling towers.....	332.00
Stretching, splicing and mounting rope, attaching clips and baskets.....	255.00
Total labor cost of construction.....	\$ 2,123.70
Opening and maintaining roads.....	1,822.20
Ropeway, materials and transportation.....	15,454.00
Total cost in running order.....	\$19,400.00

This is equivalent to about \$10,000 a mile. During 9 mos. the ropeway was operated at a cost of \$400 a month, and handled 660 cords per month; the items of cost being as follows for 9 mos.:

1 brakeman, at \$52 per mo.....	\$ 468
3 men filling, at \$25 per mo. each.....	702
1 man dumping, at \$40 per mo.....	360
1 man looking after line and oiling, at \$24.....	234
Oil	117
Repairing (very heavy, \$2.25 per day).....	526
2 men wheeling wood away from terminal.....	468
2 men receiving wood from choppers and delivering it to packers.....	702
Total for 9 mos.....	\$2,577

It will be noted that the cost of labor was low, being \$1 a day for common labor. The cost of cutting and delivering wood to the tramway was \$2.20 per cord, and the cost of transporting by the tramway, as above given, was 60 cts. per cord (not including interest on the plant). During the previous year the cost of cutting and teaming wood had been \$12 per cord. The total saving to the company, after deducting cost of tramway, was \$23,500 the first year.

Cost of Planting Trees at Washington, D. C.—During the fiscal year ending June 30, 1909, the Office of Trees and Parkings, of the Engineer Department of the District of Columbia, set out 2,988 young trees in the various streets of Washington and the District. Of this total 2,408 trees were planted in the fall season and the remainder in the spring season. The principal kinds of trees planted were elm, 626; Norway maple, 825; pin oak, 316; silver maple, 495, and sycamore, 978. The labor cost of planting the trees was as follows:

	Total.	Per tree.
Miscellaneous nursery work.....	\$ 3,165	\$0.794
Digging tree holes.....	9,897	2.182
Planting trees.....	2,394	.600
Total labor.....	\$15,456	\$3.576

**Engineering-Contracting*, Dec. 29, 1909.

The cost of lumber for tree boxes and stakes, straps, strap iron and nails amounted to \$1.41 per tree. This added to the labor cost makes the cost per tree \$5.386. This cost is an increase of nearly 16 per cent over the cost of similar work in the previous year, the principal reason being the increased cost of skilled labor and the very large amount of nursery planting done.

Cost of Tree Planting by the Massachusetts Highway Commission.*—In 1904 the Massachusetts Highway Commission began the planting of trees along state roads. The total number of trees planted that year was 3,907, the varieties being as follows: 1,737 maples, sugar, Norway and white; 538 oak, red, scarlet, white and pin; 1,000 elm, 207 poplar and some white pine and locust. The total cost of these trees in their final location, including transplanting in a temporary nursery, care, manure, superintendence and labor, was \$4,348.52, or an average of \$1.14 per tree. During the fall of 1904 there was an unusually severe drought, which had a marked effect on the trees planted at the time. The total loss of trees was 15 per cent, this loss being traceable in a large degree to the dry weather. As a result greater care was taken in 1905 in preparing the ground for the reception of the trees. In 1905 the commission began placing in the state nursery all trees received from the nurserymen, so that the trees might get added development of root fibers. This made necessary two transplantings before the tree reached its final location. The cost of trees, transplanting, preparation of ground and final planting, in 1905, was \$1.61 per tree. The original cost of each tree was higher in 1904, but more care was given to the preparation of the ground. The work for the year was as follows: Trees replaced, 726; new plantings, 3,239; vines planted, 300. In 1906 the systematic planting of trees along the state highways was continued, 2,511 new trees being planted that year. In addition 1,011 trees were replaced. The cost of planting the new trees in 1906, including the cost of tree and every expense connected therewith was \$1.10 each. The cost of the maintenance of trees planted previous to 1906 was 16 cts. per tree, and including the cost of replaced trees 20 cts.

Cost of Digging Holes and Planting Trees and Shrubs.†—In carrying on many earthwork jobs, the engineer not only has to think and plan for the engineering features of the work, but also has to consider the artistic side, namely, the landscape features. This is rapidly becoming the case with railroad work, as the right of way of some of our larger roads is being terraced, hedges planted, and banks sodded or seeded, and the station grounds made into smooth lawns with shrubs and trees to ornament them, and well kept drives laid out through the grounds. Sewerage disposal plants, reservoirs and filter beds are likewise treated in this manner. This has made landscape architecture or engineering more prominent, and the civil engineer finds that he must give attention to these

**Engineering-Contracting*, April 29, 1908.

†*Engineering-Contracting*, Jan. 1, 1908.

matters. If he has much of this work to do he will call in an expert on the subject, but if the work does not warrant this expense, he will attend to the details himself.

The cost of trees can be obtained from any nursery company, but the cost of planting is more difficult to obtain.

One of the editors of this journal has done this work upon several occasions, and the following costs were kept several years ago.

The trees in the first example were known as 4 to 6 in. trees, that is, trees measuring from 4 to 6 in. in diameter. They were maples and poplars, and were bought in the early spring and "healed" in, on a nearby lot to be planted later.

Example 1. In this lot there were 80 trees. The ground had been graded, to a depth of 1 to 5 feet, hence there was no soil left. For this reason it was necessary to dig a deep hole and fill it in with good soil so as to give the tree every chance of growing. The spread of the roots was about $2\frac{1}{2}$ ft. on the trees, hence a hole 5 ft. in diameter and 5 ft. deep was dug. Two men working together dug the holes, digging four such holes in a day. A pick and short shovel were used by them. The dirt was thrown on the side of the hole, wheel scrapers moving it away, but this cost was not charged against the tree planting as it saved borrowing that much earth elsewhere, hence this was charged against the borrow that was being made to fill in an adjoining marsh. In each hole there was 3.6 cu. yds. of earth. The wages paid for a nine-hour day were as follows:

Foreman	\$3.50
Men	1.50
4-horse team and driver.....	7.50
1-horse cart and driver.....	3.50

About six men worked in the gang, and the cost of digging the 80 holes was:

Foreman, $8\frac{1}{2}$ days.....	\$22.75
Men, 40 days.....	60.00
Total	\$82.75

The cost per hole was:

Foreman	\$0.28
Men	0.76
Total	\$1.03

This gave a cost per cubic yard of earth excavated as follows:

Foreman	\$0.08
Men	0.21
Total cost per cubic yard.....	\$0.29

It must be remembered that this kind of excavation is very similar to trench work, and also to shaft sinking, as the picking is always from the top of the excavation, and in shoveling, the

shovel cannot be heaped as easily as when working against a breast.

In planting these trees soil had to be hauled several hundred feet from nearby stock piles. Wood earth was also hauled from a piece of woodland a half a mile away. Twenty-five cents a yard was paid for the privilege of getting it, and the cost of hauling and loading it is included in the cost of the tree planting. A four-horse dump wagon that carried 2 cu. yds. each trip was used for this. This wagon also hauled some loads of "mulch" from the seashore close by, a haul not exceeding 700 ft. A cart was used to haul soil and water.

The method of planting the trees consisted in filling in the bottom of the hole for about 2 ft. with soil, then using a mixture of soil and woods earth, to fill up the hole within a few inches of the top. The roots of the tree were covered with about 10 in. of this mixture of soil. The last few inches was of the "mulch" from the seashore, as this kept the ground moist and prevented it from baking. As the tree was planted, plenty of water was poured around it. The placing of rich soil around the roots and the watering allowed the fibrous roots to begin at once to take nourishment for the tree. The planting was done in the summer time, thus making it necessary to take unusual precaution that the tree should grow. After the trees were planted they were watered and sprayed each day that it did not rain.

The cost of the tree planting for these 80 trees was as follows:

Foreman, 3½ days.....	\$12.25
Men, 20½ days.....	31 00
Team, 4 days.....	30 00
Cart, 4 days.....	14.00
Wood's earth, 12 cu. yds. at 25c.....	3.00
Total	\$90.25

This gives a cost per tree of the following:

Foreman	\$0.15
Men	0.39
Team	0.37
Cart	0.18
Wood's earth.....	0.04
Total	\$1.13

This makes a total cost per tree, of digging the holes and planting, of \$2.16.

Example II. In this case 270 trees of about the same size were planted. The work was done in the fall of year, after the map was down, and the ground in which they were planted had several feet of fairly good soil on it. The tree holes were made, for this reason, 5 ft. in diameter, but only 4 ft. deep. This meant the excavation of 2.9 cu. yds. for each hole. The wages paid for a 9-hour day were the same as in Example I, but, instead of working only about six men in the gang, about 24 men were worked. It

will be noticed that this materially reduced the foreman cost. The cost of digging the 270 holes was:

Foreman, 4 days.....	\$ 14.00
Men, 95 days.....	142.50
Total	<u>\$156.50</u>

The cost per hole was as follows:

Foreman	\$0.05
Men	0.53
Total for hole.....	<u>\$0.58</u>

The cost per cubic yard of earth excavated from the holes was:

Foreman	\$0.02
Men	0 18
Total cost per cubic yard.....	<u>\$0.20</u>

A comparison of this with the cost of digging the holes for the 80 trees will prove interesting. The unit cost of the foreman was reduced as explained by increasing the size of the crew of laborers, but it will be noticed that cutting off a foot of the depth (25 per cent) of the hole, decreased the cost of digging about 30 per cent. The cost of excavating per cubic yard was decreased 14 per cent. Two men working together nearly completed six 4-ft. holes in a day.

In planting the trees the same earth and soil that was dug from the hole was put back, hence the cost of planting includes the labor of back filling, the getting of the tree from the "healing in ground," the placing of it, putting some little manure around the tree after it was planted and watering while planting. No teams were necessary for this, the cost being as follows:

Foreman, 1½ days.	\$ 5.25
Men, 36 days.....	54.00
Total	<u>\$59.25</u>

The cost per tree was:

Foreman	\$0.02
Men	0 20
Total	<u>\$0.22</u>

This makes a total cost of planting each tree of 80 cts., and illustrates how much cheaper the work can be done when the season is favorable, and the soil does not have to be hauled and prepared to place around the trees.

Example III. In this case 60 evergreen trees of various kinds from 3 ft. to 12 ft. high were planted. Earth was taken up with the roots, at the nursery where they were bought, and burlap was tied around the roots to keep this earth from falling off. As these trees were unloaded from the car, they were carried by the men directly to the place they were to be planted. Teams could not be used for this, as the lawns, which were new, would have been

ruined by the passage of wheels over them. From 2 to 4 men were needed with hand sticks to carry each tree. The holes dug were about $2\frac{1}{2}$ ft. in diameter and about 18 in. deep, there being about 5.4 cu. ft. of earth excavated from each hole. The back filling was done from this material, which was piled up around the tree, leaving but little excess to be hauled away in wheelbarrows. Large pieces of canvas were laid down on the grass to hold the excavated earth, thus preventing the earth from injuring the grass. The entire lot of trees was planted in one day, and the cost consists of unloading the trees from the cars, carrying them to place, digging holes, planting trees, and cleaning up the ground and pieces of canvas afterwards. The ground was wet enough from recent rains to do away with watering the newly planted trees. The entire cost of this work was:

2 foremen, at \$2.50.....	\$ 7.00
3 men, at \$1.50.....	49.50
Total	<u>\$56.50</u>

The cost per tree was as follows:

Foreman	\$0.115
Men	9.825
Total	<u>\$0.940</u>

Example IV. This job consisted of planting 1,200 shrubs. About one-third of them were planted as separate shrubs or three or four plants in the same hole, the rest being planted as hedges. The holes were dug 1 ft. deep. A foreman and 3 men did the work, taking the shrubs from the "healing in ground," digging the holes, planting, back filling and watering. The wages were the same as paid in the other examples. The cost was as follows:

Foreman, 5 days.....	\$17.50
Men, 15 days.....	22.50
Total	<u>\$40.00</u>

This was a cost of a little more than 3 cents per shrub. All the work was done by day labor.

SECTION X.

BUILDINGS.

Cost of Items of Buildings by Percentages.—In any locality, if we select buildings of any given class and estimate the percentage of the total cost chargeable to each item, we find a remarkably small

	Frame Buildings.	Brick Residences.	Brick Flats and stores.	Brick Schools.	Brick Warehouses.	Machine Shops (150 x 400).
Excavation, brick and cut stone	16%	36%	38%	48%	50%	15%
Plaster	8	6	6½	6	10
Skylights and glass....	21	20	17	10½	7	6
Millwork and glass....	19	12	11½	11½	18½	6½

Gravel roofing	5½	45½
Structural steel	8½	6
Steel lintels and hard- ware	7	3	4	4	2
Plumbing and gas fitt'g	8
Piping for steam, water and power...	5	5½	4½	4	2½	2
Paint	100%	100%	100%	100%	100%	100%
Total						

Note.—Heating is not included.

variation. For example, the hardware item in brick residences averages about 3% of the total cost of the building whether the building costs \$10,000 or \$50,000. For a \$10,000 building the hardware costs $\$10,000 \times 3\%$, or \$300. For a \$50,000 building, the hardware costs $\$50,000 \times 3\%$, or \$1,500. In making preliminary estimates of cost it is often sufficiently close to estimate one or two of the large items and calculate the rest by percentages. Every builder and architect, therefore, should analyze the actual cost of each item of a number of typical buildings, and reduce the analysis to percentages. Where foundation work is difficult and variable, it is well to exclude the foundations in forming a table of percentages, such as the one on this page. It is also well to carry the subdivisions of cost still farther; but for the purpose of example, the foregoing table serves to illustrate.

Cost of Buildings Per Cu. Ft.—In order approximately to estimate the cost of any proposed building for which plans have not yet been prepared, it is convenient to estimate the cost in cents per cubic foot. In the following examples the cubic contents are computed from the cellar floor to the roof (if the roof is flat), or (in a pitch roof) to the top of the attic walls that are finished or may be finished; but air spaces and open porches are not included. Measurements are from out to out of walls and foundations.

The following figures were compiled by Mr. James N. Brown, of St. Louis, and form part of the instructions to insurance adjusters. Prices were for the year 1902.

<i>Country Property:</i>	Cts. per cu. ft.
Frame dwelling, small box house, no cornice.....	4
Frame dwelling, shingle roof, small cornice, no sash weights, plain.....	5 to 6
Brick dwelling, same class.....	7 to 8
Frame dwelling, shingle roof, good cornice, sash weights, blinds (good house).....	7 to 8
Brick dwelling, same class.....	9 to 10
Frame barn, shingle roof, not painted, plain finish.....	1 1/2 to 2 1/4
Frame barn, shingle roof, painted, good foundation....	2 1/4 to 3
Frame store, shingle roof, painted, plain finish.....	5 to 7
Brick store, shingle roof, painted, good cornice, well finished.....	7 to 9
Frame church or schoolhouse, ordinary.....	5 to 7
Brick church or schoolhouse, ordinary.....	8 to 10
If slate or metal roof, add 1/2 ct. per cu. ft. to the above.	

<i>City Property:</i>	
Frame dwelling, shingle roof, pine floors and finish, no bathroom or furnace, plain finish (good house).....	6 to 7
Brick dwelling, same class.....	8 to 9
Frame dwelling, shingle roof, hardwood floor in hall and parlor, bath, furnace and fair plumbing.....	8 to 9
Brick dwelling, same class.....	8 to 10
Frame dwelling, shingle roof, hardwood in first floor, good plumbing, furnace, artistic design, some interior ornamentation, well painted.....	10 to 12
Brick dwelling, good plumbing, bath, furnace, pine finish, well painted.....	11 to 12

Cost of Miscellaneous Buildings.—Mr. Fred T. Hodgson published the following in the *Architects' and Builders' Magazine*, May, 1902:

Bathhouses, complete, or for barracks, but not supplied with hot water, per cu. ft.....	.45 to \$.50
Or per bath.....	280.00 to	320.00
Baths, public, comprising swimming baths, slipper baths, laundry, caretaker's quarters, machinery, etc., complete, per cu. ft.....	.30 to	.36
Breweries, complete, including buildings, cellarage, boilers, engine, machinery, coppers, liquor baths, mash tubs, coolers, refrigerator, ice storage, pumps, and all other requirements, per cu. ft.....	.14 to	.20
Churches, plain, per cu. ft., from.....	.16 to	.22
Per sq. ft., from.....	4.50 to	6.50
Per sitting, from.....	40.00 to	55.00
Churches, ornamental, per cu. ft., from.....	.23 to	.29
Per sq. ft., from.....	7.00 to	12.50
Per sitting, from.....	65.00 to	120.00

BUILDINGS.

Per cu. ft.....	.23 to	.38	
Chimney shafts, plain, as for factories, etc., complete, including foundations, iron cap, etc., height measured from surface of ground to top of cap:			
	Per ft. in height.		
Not exceeding 100 ft. in height.....	\$ 40.00 to \$	46.00	
100 ft. to 180 ft. high.....	45.00 to	51.00	
180 ft. to 250 ft. high.....	50.00 to	56.00	

Costs of Concrete Buildings.*—A common method of stating the cost of buildings for approximate estimates and comparisons is in terms of dollars per square foot of floor or cents per cubic foot of space inclosed. Either unit has been supposed to be a reliable one for approximate comparisons and both have been used frequently to prove in individual cases the economy or the high cost of construction work. In view of these facts the following comparisons made by Mr. Leonard C. Wason, president, Aberthaw Construction Co.

TABLE I.—COST OF FIREPROOF COMPLETED CONTRACTS.

Kind of Building.	Volume in cu. ft.	Floor area in sq. ft.	Unit cost	
			Per cu. ft.	Per sq. ft.
Offices and stores....	1,365,820	90,474	\$0.133	\$2.00

Boston, Mass., will be of decided interest. In preparation for a study of the figures given it is important to note that Mr. Wason's conclusions are that, after making this comparison, he is con-

vinced that neither method is accurate enough to put much reliance on, but that the square foot method is a little safer than the other.

The comparative figures compiled by Mr. Wason are given in Tables I to IV, inclusive. In each case the total cost includes masonry and carpentry work without interior finish or decorating, plumbing and heating. The effort has been made to put the buildings upon a comparative basis as regards the amount of work done on each.

The first table consists of the total cost of actual contracts executed. The second table consists of bona fide bids on complete buildings on which Mr. Wason's company were not the lowest bidders, but where the difference was not as a rule very great. The third and fourth tables are bona fide bids on work by another contractor whose experience was similar to that of Mr. Wason's. As a rule, cubic foot measurements are given in cents only, seldom being carried to any closer subdivision. In reference to Table IV on second-class buildings, it will be noted that for the largest building a variation of 1 ct. per cu. ft., amounts to over \$28,000, while the smallest one in the list amounts to only a little over \$5,400. Again, on the last three items, the cubic foot price is practically identical, while the square foot measurements corresponding vary by more than 100%, with no easily apparent reason in the design.

In Table III another discrepancy is noticed. In the first and the last items, the highest and the lowest per cubic foot, as well as per square foot are on office buildings of similar type which were within one mile of each other where there is no apparent reason for such discrepancy in the design or difficulty or access in the erection of the building.

Cost of Fireproof Office Buildings.—Mr. F. J. T. Stewart gathered the following data in 1906.

The average cost of 3 office buildings in Chicago was 33 cts. per cu. ft., distributed as follows:

	Per cent.
Foundations	4.3
Steel frame	15.2
Mason work	25.5
Equipment (elevators, plumbing, lighting, heating, ventilating, etc.)	25.0
Trim and finish	30.0
Total	100.0

The average cost of 4 office buildings in Boston was 40 cts. per cu. ft., distributed as follows:

	Per cent.
Foundations	7.0
Steel frame ..	18.4
Mason work	35.5
Equipment	18.5
Trim and finish	20.6
Total	100.0

Comparative Cost of Wood and Steel Frame Factory Buildings.—Mr. H. G. Tyrrell gives the following, based on prices existing in Ohio in the forepart of 1905.

Slow Burning Wood Construction.—The building is 60 x 100 ft., six stories high, containing 6 floors, a roof and a cellar. The floors are designed for a load of 100 lbs. per sq. ft. The building has windows on all four sides. The walls (brick) carry the ends of the floor beams. The basement walls are 24 ins. thick. Walls of first four stories are 17 ins. thick; top two stories, 13 ins. thick. Eight tiers of columns, spaced 20 ft. apart in both directions, carry the floors and roof. The columns of the upper four stories are yellow pine, the size being 14 x 14 ins. for the lowest of these four stories. Below this, round cast iron columns are used, 11 x 1½ in. in the first story, and 13 x 1½ ins. in the basement. All columns have cast iron bases 3 ft. square and 16 ins. high. Lengthwise through the building in the floors, run two lines of 12 x 20-in. yellow pine header beams resting on the brackets of the cast iron column caps. The cross floor beams are 8 x 16-in. yellow pine, spaced 5 ft. apart. At the columns they rest on column caps, and at intermediate points they hang from the header beams by wrought iron stirrups. In the walls the cross beams rest on cast iron wall plates, 9 x 20 x ¾ in. The floor is of ¾-in. matched maple, laid on 1½-in. yellow pine. The roof is similar in construction and has a tar and gravel covering.

The following estimates are for the structural part of the building only, including walls, columns, floors, roof, excavation, foundation, doors and windows, but not including partitions, stairs, elevators, plumbing, heating, lighting or wiring.

1. Excavation (cu. yds.).....	1,800
2. Cellar cement floor (sq. ft.).....	6,000
3. Foundation concrete (cu. yds.).....	150
4. Brick (cu. ft.).....	39,000
5. Windows, 4 x 7 ft.....	238
6. Roofing (sq. ft.).....	6,000
7. Yellow pine timber (M.).....	116
8. Yellow pine flooring (M.).....	73
9. Matched flooring (M.).....	46
10. Iron work (tons).....	46.

The estimated cost of this design is \$35,000, which is equivalent to 6.1 cts. per cu. ft., or 83 cts. per sq. ft. of entire floor area.

The interior framing of floors and columns (including wall plates, columns, caps and bases and stirrup irons), is 27 cts. per sq. ft. of floor area.

Fireproof Steel Construction.—This is similar in design to the above, as regards arrangement of beams and columns. Riveted steel columns are used, and the floors are framed with steel beams. The flooring between the beams is reinforced concrete.

The quantities are as before for items (1) to (6) inclusive.

The remaining items are:

7. Steel columns (tons).....	105
8. Steel beams and wall plate (tons).....	252
9. Concrete floor and roof (sq. ft.).....	42,000

The estimated cost is \$57,000, which is equivalent to 10.2 cts. per cu. ft., or \$1.36 per sq. ft. of total floor area. Floors and

columns cost 75 cts. per sq. ft. of floor area, as compared with 27 cts. for the slow burning mill construction.

Cubic Foot Costs of Reinforced Concrete Buildings.*—The following costs are for buildings actually erected and they are given by Mr. Emile G. Perrot, M. Am. Soc. C. E.:

	Cents per cu. ft.
Warehouses and manufacturers.....	8 to 10
Stores and loft buildings.....	11 to 17
Miscellaneous, such as schools and hospitals...	15 to 20

COST IN DOLLARS PER SQ. FT.

Eng.-Contr. **LENGTH IN FEET**

Fig. 1.

These costs include the building complete, omitting power, heat, light, elevators and decorations or furnishings.

Cost of Mill Buildings.—Mr. Charles F. Main is authority for the following data, based upon eastern prices in 1910.

It is not an uncommon thing to hear the cost of mill buildings placed from 70 cts. to \$1 per sq. ft. of floor space, regardless of the size or number of stories. There is, however, a wide range of cost

**Engineering-Contracting*, Jan. 27, 1909.

per square foot of floor space, depending upon the width, length, height of stories and number of stories.

Some time ago, I placed a valuation upon a portion of the property of a corporation, including some 400 or 500 buildings. In order to have a standard of cost from which to start in each case, I prepared a series of diagrams showing the approximate costs of buildings varying in length and width and from one story to six stories in height. The height of stories also was varied for different widths, being assumed 13 ft. high if 25 ft. wide, 14 ft. if 50 ft. wide, 15 ft. for 75 ft., 16 ft. for 100 ft. and over.

Cost in Dollars per Sq. Ft.

Eng. Only. *LENGTH IN FEET*

Fig. 2.

The costs used in making up the diagrams are based largely upon the actual cost of work done under average conditions of cost of materials and labor and with average soil for foundations. The costs given include plumbing, but no heating, sprinklers, or lighting. These three latter items would add roughly 10 cts. per sq. ft. of floor area.

Estimates.—The accompanying diagrams, Figs. 1 to 6, can be used to determine the probable approximate cost of proposed brick

HANDBOOK OF COST DATA.

ings, of the type known as "slow-burning" to be used for facturing purposes, with a total floor load of about 75 lbs. sq. ft. and these can be taken from the diagrams readily. The s were derived primarily to show the estimated cost per e foot of gross floor area of brick buildings for extile mills, o include ordinary foundations and plumbing. For example, is desired to know the probable cost of a mill 400 ft. long 0 ft. wide, three stories high, refer to the curves showing the of three-story buildings. On the curve for buildings 100 ft.

Cost in Dollars per Sq. Ft.

LENGTH IN FEET.

Eng.-Contg.

Fig. 3.

find the point where the vertical line of 400 ft. in length cuts curve, then move horizontally along this line to the left-hand al line, on which will be found the cost of 81 cts.
cost given is for brick manufacturing buildings under average tions and can be modified if necessary for the following con- s:

If the soil is poor or the conditions of the site are such as to e more than the ordinary amount of foundations, the cost will eased.

(b) If the end or a side of the building is formed by another building, the cost of one or the other will be reduced slightly.

(c) If the building is to be used for ordinary storage purposes with low stories and no top floors, the cost will be decreased from about 10% for large low buildings, to 25% for small high ones, about 20% usually being a fair allowance.

(d) If the buildings are to be used for manufacturing purposes and are to be substantially built of wood, the cost will be decreased

COST IN DOLLARS PER SQ. FT.

FEET IN MIN.

25

50

75

100

25

Eng.-Conty

Fig. 4.

from about 6% for large one-story buildings, to 33% for high small buildings, 15% would usually be a fair allowance.

(e) If the buildings are to be used for storage with low stories and built substantially of wood, the cost will be decreased from 13% for large one-story buildings, to 50% for small high buildings; 30% would usually be a fair allowance.

(f) If the total floor loads are more than 75 lbs. per sq. ft. the cost is increased.

(g) For office buildings, the cost must be increased to cover architectural features on the outside and interior finish.

The cost of very light wooden structures is much less than the above figures would give. Table IVa shows the approximate ratio of the costs of different kinds of buildings to the cost of those shown by the curves.

Evaluations.—The diagrams can be used as a basis of valuation of different buildings.

A building, no matter how built nor how expensive it was to build, cannot be of any more value for the purpose to which it is

COST IN DOLLARS PER SQ. FT.

LENGTH IN FEET

Eng.-Only.

Fig. 5.

put than a modern building properly designed for that particular purpose. The cost of such a modern building is then the limit of value of existing buildings. Existing buildings are usually of less value than new modern buildings for the reason that there has been some depreciation due to age and that the buildings are not as well suited to the business as a modern building would be.

Starting with the diagrams as a base, the value can be approximately determined by making the proper deductions.

The diagrams can be used as a basis for insurance valuations after deducting about 5% for large buildings to 15% for small ones.

for the cost of foundations, as it is not customary to include the foundations in the insurable value.

Use of Tables.—Table V shows the costs which form the basis of the estimates and these unit prices can be used to compute the cost of any building not covered by the diagrams. The cost of brick walls is based on 22 bricks per cubic foot, costing \$18 per thousand laid. Openings are estimated at 40 cts. per sq. ft., including windows, doors and sills.

COST IN DOLLARS PER SQ. FT.

Eng. Only. **LENGTH IN FEET**

Fig. 6.

Ordinary mill floors, including timbers, planking and top floor with Southern pine timber at \$40 per M. ft. B. M. and spruce planking at \$30 per M., costs about 32 cts. per sq. ft., which has been used as a unit price. Ordinary mill roofs covered with tar and gravel, with lumber at the above prices, cost about 25 cts. per sq. ft. and this has been used in the estimates. Add for stairways, elevator wells, plumbing, partitions and special work.

Deductions from Diagrams.—(1) An examination of the diagrams shows immediately the decrease in cost as the width is increased.

This is due to the fact that the cost of the walls and outside foundations, which is an important item of cost, relative to the total cost, is decreased as the width increases.

For example, supposing a three-story building is desired with 30,000 sq. ft. on each floor:

If the building were 600 ft. x 50 ft., its cost would be about 99 cts. per sq. ft.

If the building were 400 ft. x 75 ft., its cost would be about 87 cts. per sq. ft.

If the building were 300 ft. x 100 ft., its cost would be about 83 cts. per sq. ft.

If the building were 240 ft. x 125 ft., its cost would be about 80 cts. per sq. ft.

(2) The diagram shows that the minimum cost per square foot is reached with a four-story building. A three-story building costs a trifle more than a four-story. A one-story building is the most expensive. This is due to a combination of several features:

(a) The cost of ordinary foundations does not increase in proportion to the number of stories, and therefore their cost is less per square foot as the number of stories is increased, at least up to the limit of the diagram.

(b) The roof is the same for a one-story building as for one of any other number of stories, and therefore its cost relative to the total cost grows less as the number of stories increases.

(c) The cost of columns, including the supporting piers and castings, does not vary much per story as the stories are added.

(d) As the number of stories increases, the cost of the walls, owing to increased thickness, increases in a greater ratio than the number of stories, and this item is the one which in the four-story building offsets the saving in foundations and roof.

(3) The saving by the use of frame construction for walls instead of brick is not as great as many persons think. The only saving is in somewhat lighter foundations and in the outside surfaces of the building. The floor, columns, and roof must be the same strength and construction in any case.

Assumed Height of Stories.—From ground to first floor, 8 ft. Buildings 25 ft. wide, stories 13 ft. high. Buildings 50 ft. wide, stories 14 ft. high. Buildings 75 ft. wide, stories 15 ft. high. Buildings 100 ft. wide, stories 16 ft. high. Buildings 125 ft. wide, stories 16 ft. high.

Unit Prices.—Floors, 32 cts. per sq. ft. of gross floor space not including columns. If columns are included, 38 cts.

Roof, 25 cts. per sq. ft., not including columns. If columns are included, 30 cts. Roof to project 18 ins. all around buildings.

Stairways, including partitions, \$100 each flight. Allow two stairways, and one elevator tower for buildings up to 150 ft. long. Allow two stairways and two elevator towers for buildings up to 300 ft. long. In buildings over two stories, allow three stairways and three elevator towers for buildings over 300 ft. long.

In buildings over two stories, plumbing \$75 for each fixture including piping and partitions. Allow two fixtures on each floor up

50,000	.94	.88	.86	.84	.82	.80	.93	.88	.86	.84	.82	.82	.83	.51	.58	.58	.53	.51

to 5,000 sq. ft. of floor space and add one fixture for each additional 5,000 sq. ft. of floor or fraction thereof.

(Note.—From the above data the approximate cost of any size and shape of building can be estimated in a few minutes. After the cost of the items given is determined about 10% should be added for incidentals.)

Reinforced Concrete Buildings.—From such estimates and proposals as I have been able to get and from work done it appears that the cost of reinforced concrete buildings designed to carry floor loads of 100 lbs. per sq. ft. or less would be about 25% more than the slow-burning type of mill construction.

Alternate Method of Estimating Cost.—Floors.—38 cts. per sq. ft. of gross floor space. This price will include column piers, column castings and wrought iron.

Roof.—20 cts. per sq. ft., including projections, say 18 ins., including columns, etc.

Stairways and Elevator Towers.—Allow two stairways and one elevator tower in buildings over two stories high up to 150 ft. long. Allow two stairways and two elevator towers up to 300 ft. long. Allow three stairways and three elevator towers over 300 ft. long.

Brick Walls.—Enclosing stairs and elevators, estimated as inside walls.

Stairs.—\$100 per flight, per story.

Plumbing.—Allow two fixtures on each floor up to 5,000 sq. ft. of floor space, and add one fixture for each additional 5,000 sq. ft. or fraction thereof. Allow \$75 per fixture.

Incidentals.—Add about 10% for incidentals.

TABLE V.—DATA FOR ESTIMATING COST OF BUILDINGS.

	Foundations including exc. Cost per lin. ft. for outside inside walls walls		Brick Walls Cost per sq. ft. of surface. outside for inside walls walls		Columns including piers and castings Cost of one.

Estimating Quantity of Lumber.—Lumber is measured in feet board measure, as explained on page 487.

There are 15 or more associations in America having rules governing the inspection and classification of lumber. The following three have printed rules that are particularly valuable to have: The National Hardwood Lumber Association, Chicago; Southern Lumber Manufacturers' Association, St. Louis; Mississippi Valley Lumbermen's Association, Minneapolis, Minn.

In building a house, there is always a considerable percentage of waste lumber. Then, too, there is the loss in surface area in forming tongues and grooves at the mill, and in dressing the edges. Therefore, after computing the exact number of pieces, or the exact area, as shown in the plans for the building, it is necessary to add considerably to the lumber bill to cover the waste.

To estimate the number of joists for each room, count the actual number and add 1 joist; for an extra joist is needed for the wall. Joists are nearly always "bridged," and for this purpose 2 x 4-in. stuff is used. The "bridging" is the inclined bracing between the joists.

Allow 25 lin. ft. of 2 x 4-in. bridging for each "square" (100 sq. ft.) of flooring. Where 2 x 12-in. joists are placed 16 ins. apart, it will be found that the 2 x 4-in. bridging amounts to about 9% of the number of ft. B. M. of joists.

On a plain roof count the number of rafters and add 1 extra.

In estimating the number of studs for walls and partitions, allow 1 stud for every lineal foot of wall or partition where studs are "spaced 16 ins. centers," that is 16 ins. center to center. This seemingly large allowance is made to cover the doubling of studs on corners, doors and windows. For a stable or shed no such extra allowance need be made.

To estimate the quantity of sheathing or of shiplap, calculate the exact surface to be covered, deducting openings, then add the following percentages:

	Sheeting. Per cent.	Shiplap. Per cent.
For floors	15	17
For sidewalks.....	17	20
For roofs.....	20	25

Sheathing is laid with 2-in. spaces on cheap roofs, then deduct accordingly. Sheeting and shiplap are sometimes laid diagonally, then add 5% to the above figures to cover waste in sawing both ends.

Remember that lumber comes in lengths of even feet, and, with few exceptions, 16 ft. is the maximum stock length. Examine each area to be covered to see whether a given number of standard lengths will cover it, or whether there will be a waste on each length.

To estimate the amount of siding, calculate the exact surface, deducting openings, and add 33%, if 6-in. siding with 4½ ins. to the weather; but if it is 4-in. siding add 50% to the actual surface.

There are two classes of flooring, namely, "dressed or square edge flooring," and "dressed and matched flooring." The square

edge flooring ordinarily has a face width about $\frac{1}{2}$ in. less than its nominal width; thus, a piece of 6-in. square edge flooring has a face width of $5\frac{1}{2}$ ins., and a piece of 4-in. flooring has a face width of $3\frac{1}{2}$ ins. The loss in the case of the flooring with $5\frac{1}{2}$ -in. face is 9%, and in the case of the $3\frac{1}{2}$ -in. face, the loss is 14%. But in addition to these mill losses, there is generally waste owing to bad ends, etc., so that after estimating the exact area of floor, add the following percentages:

	Per cent.
For 6-in. flooring, add.....	11
For 4-in. flooring, add.....	20

The following gives a fair extra allowance where dressed and matched flooring is to be laid:

	Per cent.
For 6-in. flooring, add.....	17
For 4-in. flooring, add.....	25
For $2\frac{1}{2}$ -in. flooring, add.....	33
For $1\frac{1}{2}$ -in. flooring, add.....	40

Remember that if the flooring is to be laid under partitions, due allowance must be made. If the architect has so spaced the joists that full standard lengths can not be used, there may be a very large waste not included in the above allowances; thus, if the width of room is such as to require flooring 12 ft. 2 ins. long, it will be necessary to buy flooring 14 ft. long, and saw off nearly 2 ft., which is wasted. Flooring less than 1 in. thick is estimated as being 1 in. thick.

Ceiling and Wainscoting are estimated just as dressed and matched flooring is estimated.

Cost of Timberwork in 5 Different Kinds of Buildings.—In the following table is given the average cost of timberwork in a number of different buildings. Each building is briefly described in the table, and the cost is the average of all the rough lumber in it, and does not include the work on the milled, or dressed lumber. Only carpenters were engaged on this work, and they handled all the lumber after its delivery in wagons at the site of the work. Wages of carpenters were 40 cts. per hr. No common laborers employed.

Building number		Ft. B. M. per man per day of 8 hrs.	Cost per M., wage being \$3.20 for 8 hrs.
1	A block of six 3-story "flats," first story veneered with brick; rest covered with slate; an expensive front; towers.....	275	\$11.60
2	Same type of building with a plain front	375	8.50
3	Three-story schoolhouse, plain; including sheeting, shiplap, and all plain lumber except flooring.....	400	3.00
4	Three-story business building.....	475	6.80
5	Heavy warehouse, mill construction.....	550	5.80
6	A plain two-story building, with a 2-in. flooring roof, and plank under-floors...	385	3.30

Cost of Framing and Placing Lumber.—The following table gives the actual cost of the carpenter work involved in doing the different classes of work enumerated. No common laborers were employed.

	Ft. B. M. per man per day of 8 hrs.	Cost per M., wage being \$3.20 for 8 hrs.
Joists: In a four-story brick business block, having steel girders, 3 x 14-in. joists delivered sized, average cost of work on joists and sheeting (not including hoisting which was \$2 per M. for second story and up).....	550	\$ 5.80
Joists: In a three-story, plain, electric light building, with flat roof, 3 x 12-in. joists, including sizing of joists.....	400	8.00
Joists and floor: In a warehouse, joists dropped into stirrups, and a heavy plank floor.....	500	8.40
Bridging: 2 x 4-in. bridging between joists.....	150	21.30
Sleepers: For a railroad machine shop, 6 x 8-in. sleepers buried in sand.....	380	8.40
Plank floor: The 3-in. plank floor laid on the sleepers above described.....	450	7.10
Purlins: For a warehouse, including hoisting 60 ft.	265	12.10
Plank floor: A 2-in. plank floor laid on purlins that were 6-ft. apart.....	230	13.90
Sheeting for floors	800	4.00
Sheeting for roof of six-story building	500	8.40
Sheeting on frame building	500	8.40
(Note.—If sheeting is laid diagonally, add 15% to the cost of laying.)		
Rafters: 2 x 6-in. rafters for plain gable roof... ..	300	10.70
Rafters: 2 x 6-in. rafters for a hip roof	125	25.60
Roof boards: Rough boards on a plain gable roof	600	5.35
Roof boards: Rough boards on a hip roof.....	400	8.00
Siding: Rough boards on a barn.....	800	4.00
Studding: 2 x 4-in.....	350	12.80
Studding: 2 x 6-in.....	350	9.15
Sills and plates: 6 x 6-in., without gains or mortices	400	8.00
Sills and plates: 6 x 8-in., with gains but no mortices	200	16.00
Sills and plates: 6 x 8-in., with gains and mortices	135	23.70
Platform: A rough timber platform on short posts, around a warehouse, including posts, caps, joists and floor.....	400	8.00
Board fence: A close board fence, 8-ft. high (posts already set).....	400	8.00

Cost of Laying and Smoothing Floors.—In the following table is given the cost of laying matched flooring, after the joists are in place. All the cost of handling the flooring after its delivery at the building site is included. Where the width of the flooring plank is given, the face width is meant, and it should be remembered that the face width is about $\frac{1}{2}$ -in. less than the original stock width of the material before milling. A flooring that is sold by the mills as 4-in. plank, has a face width of $3\frac{1}{2}$ ins. The cost of laying is given in "squares" of 100 sq. ft.

COST OF LAYING FLOORING.

	Squares per man per day of 8 hrs.	Cost per square, wages being \$3.20 per 8 hrs.
Yellow pine: 3¼-in. face laid on sheeting, including the laying of paper between the sheeting and the flooring and including the smoothing of rough joints in the flooring, in a four-story business block.....	2	\$ 1.60
Yellow pine: 3¼-in. face, including smoothing and sandpapering, in a five-story business block, men worked very hard.....	1½	1.80
Yellow pine: 3¼-in. face, laid direct on joists, no smoothing.....	3	1.10
Maple: Square edged, 4-in. face, doubled nailed, not smoothed, in a warehouse.....	2½	1.40
Yellow pine: 4-in. face, nailed on one edge only, not smoothed, in a six-story warehouse.....	2½	1.20
Yellow pine: 3¼-in. face, including smoothing and sandpapering, in a three-story seminary, ground floor.....	1½	2.10
Ditto: Small upper rooms.....	1½	2.60
Maple: 2¼-in. face, laid but not smoothed.....	2	1.60
Maple: 2¼-in. face, laid but not smoothed, large floor of warehouse.....	3½	0.90
Maple: 2¼-in. face, laid and smoothed, houses and offices.....	1	2.20
Maple: 1¼-in. face, laid and well smoothed, houses and offices.....	¾	4.30
Maple: Smoothing only, not including laying the floor.....	1	3.20
Oak: Gluing, smoothing, scraping and sandpapering a fine floor, men working hard.....	¼	12.80
Yellow pine: 5¼-in. face, 3 ins. thick, tongue and groove, for mill building, not smoothed....	2½	1.30
Yellow pine: 5¼-in. face on bare joists, not smoothed.....	4	0.80
Ditto: Laid on top of an under-floor.....	3	1.10
Ditto: Laid on a pitched roof without many angles.....	2	1.60

Cost of Ceiling, Wainscoting and Siding.—The following table gives the cost of ceiling, wainscoting and siding:

	Squares per man per day of 8 hrs.	Cost per square, wages be- ing \$3.20 per day.
Ceiling of a store.....	1½	2.10
Smoothing an oak ceiling after laying.....	¾	4.30
Wainscoting: Cut, put up and finished with cap and quarter round.....	1½	1.80
Siding: Plain, 6-in.....	2½	1.40
Drop-siding: When window casings and corner boards are placed over the siding.....	4	0.80
Drop-siding: When joints are made against casings and corner beads.....	2½	1.30
Lap-siding.....	3	1.05
Surfaced barn boards.....	7	0.45

Cost of Shingling.—The following table gives the cost of laying shingles, shingles being well laid with $4\frac{1}{2}$ -in. exposure:

	Squares per man per day of 8 hrs.	Cost per square, wages be- ing \$3.20 per day.
Plain roof.....	2½	\$1.80
Fancy roof.....	1¾	1.80
Difficult roof, much cutting	1	3.20
Plain side walls.....	1¾	2.10
Difficult side walls.....	1	3.20

The standard bunch of shingles is supposed to contain 250 shingles averaging 4 ins. wide. Hence if shingles are laid with an exposure of $4\frac{1}{2}$ ins., each shingle covers $4 \times 4\frac{1}{2} = 18$ sq. ins., or 800 shingles to the square. But the cutting for angles, the loss of broken shingles, the double course at the eaves, and the like, necessitate a larger allowance. On plain roofs allow 8% more, and on gables 12% more than the theoretical 800. Estimate as follows:

	Plain roof. Shingles per square.	Cut-up roof. Shingles per square.
With 4-in exposure.....	980	1010
With $4\frac{1}{2}$ -in. exposure.....	880	900
With 5-in. exposure.....	790	810

Cost of Laying Base-Boards.—The amount of base-board work is computed in lineal feet, instead of board feet. The following costs relate to the actual number of lineal feet, doors and openings being deducted:

	Lin. ft. per man per day of 8 hrs.	Cost per lin.ft. wages be- ing \$3.20 per day.
Base-board: In a building with an unusually large number of pilasters.....	50	6½ cts.
Base-board: Three-membered, hardwood, average number of miters.....	50	6½ cts.
Base-board: In a plain five-story business block, two-membered base scribed to floor.....	80	4 cts.
Base-board: In a three-story seminary, narrow birch; fitting to the floor not necessary.....	100	3¼ cts.
Base-board: Plain, quarter-round at floor.....	100	3¼ cts.
Moulding: Bed, flat, 3-in.....	320	1 ct.

Cost of Placing Doors, Windows and Blinds.—The following table gives the cost of labor on doors, windows and blinds:

	Number of hrs. labor on each.	Labor cost of each, wages be- ing 40 cts. per hour.
Windows: To put frames together if stuff comes knocked down.....	1½	\$ 0.60
Window: Ordinary pine window in a frame building including setting frame.....	5	2.00
Window: Same as before, except hardwood.....	6½	2.60
Window: Ordinary pine window in brick building, including setting frame.....	6½	2.60
Window: Same as before, except hardwood.....	9	3.60
Window: 30-light (lights 10 x 14), setting frame, fitting and hanging sash, and putting on hardware, for a machine shop.....	7	2.80
Window: Same as before, but hung on sash balances ..	8	3.20
Transom: Fixed.....	1	0.40
Transom: Hung.....	1½	0.60
Door: Common hardwood, set jambs, case, hang and finish, including transom.....	10	4.00
Door: Birch door, complete, for a seminary.....	7	2.80
Door: Common pine door, 1½-in., complete.....	4½	1.80
Door: Common pine, 1½-in., complete.....	5½	2.20
Door: Pine, swinging door, no hardware except hinges ..	4	1.60
Door: Pine, finish of wide paneled jambs, with transom, for school house.....	10	4.00
Door: Same as before, but hardwood.....	12½	5.00
Sliding doors: Pine (framing not included), to finish complete with lining, jambs, casings, and hardware, per pair.....	32	12.80
Sliding doors: Same as before, but hardwood, per pair ..	48	19.20
Outside doors: Pine, 6 x 8 ft., door frame, casings, and hardware, complete, per pair.....	10	4.00
Outside doors: Same as before, but hardwood, per pair.....	14	5.60
Outside double doors: Opening 12 x 18 ft., in a factory ..	32	12.80
Sliding doors: Opening 12 x 18 ft., in a barn....	34	13.60
Blinds: If fitted before frames are set, per pair..	¾	0.30
Blinds: If fitted after frames are set, per pair...	1	0.40
Blinds: Plain pine, inside blinds, per set.....	3	1.20
Blinds: Same as before, but hardwood.....	5	2.00

The labor cost of bedding and setting 10 x 14-in. lights on a large building was 1½ cts. per light, or 1½ cts. per sq. ft.; and one-twenty-fifth of a pound of putty per lineal foot around the edge of the glass was used. With a deeper rabbet and putty not properly pressed, one-fifteenth pound per lineal foot of glass edge may be used. The cost of setting plate glass is about 7 cts. per sq. ft. Floor and sidewalk glass may be set for 5 cts. per sq. ft.; skylight glass for 8 cts. per sq. ft.

Cost of Closets and Sideboards.—The following miscellaneous labor costs will serve as a guide: The labor costs are given in dollars and cents, wages being 40 cts. per hour:

	Cost of Labor
Drawers, if dovetailed, each.....	\$ 1.00
Drawers, 15 ins. wide, 18 ins. deep, including racks and fittings, each	0.80
Shelves, in a storeroom, shelves dadoed into compartments 18 ins. square, per sq. ft. of shelf.....	0.25
Shelves, in pantry, no dadoing, per sq. ft.....	0.15
Closet hooks, on a strip of wood, hooks 12 ins. apart, per lin. ft. of strip.....	0.05
Sideboard, ash, 8 x 8 ft., drawers, doors, brackets, shelves, mirrors and hardware.....	50.00
Sideboard, oak, less detail than before.....	40.00
Sideboard, pine, fairly good.....	25.00

Cost of Making Stairs.—The labor cost of making a number of different kinds of stairs will be given, labor being 40 cts. per hour. The cost includes the making and setting of the stairs, but does not include mill work.

	Cost of Labor.
Two flights of stairs (for a school), 6 ft. wide, with ceiling rail	\$ 35.00
Three flights of oak stairs (for a hospital), 5 ft. wide with continuous rail	90.00
Three flights of oak stairs (for a seminary).....	120.00
Box-stair, long, without landing ..	9.00
Box-stair, for cellar or attic, if windows are used... ..	10.00
One flight of plain stairs, in a 7-room house.....	15.00
One flight of fine stairs, in a 9-room house.....	40.00

Cost of Tin Roofing.—The sizes of tin sheets are 14 x 20 ins., and 20 x 28 ins. An allowance of 1 in. must be made for laps at joints; with sheets 20 x 28 ins., a square (100 sq. ft.) requires 29 sheets. With 14 x 20-in. sheets, allow 43 per square, and 50% more of solder, rosin, etc. A box of tin contains 112 sheets, and the large sheets of I. C. tin weigh 225 lbs. per box; the I. X., 285 lbs. per box.

One man, at 40 cts. per hr., will lay 2 squares of plain roofing per day. One man will line about 75 sq. ft. of box gutter, or an equal amount of flashing, per day. The cost per square of tin roof was as follows:

	Per square.
29 sheets of I. C. tin, 55 lbs., at 8 cts.....	4.40
5 lbs. solder, at 14 cts.....	0.70
1½ lbs. nails, at 4 cts.....	0.06
1 lb. rosin	0.04
Labor, at 40 cts. per hr.....	1.60
Charcoal	0.10
Painting two coats.....	1.50
Total	\$8.40

A man, at 40 cts. per hr., will put up plain metal ceilings at the rate of 1½ to 2 squares per day, including cornice and centers. On a large room, and plainest kind of work, he may do 3 or 4 squares. Wainscoting, at the same rate.

A man, with a helper, will lay 12 squares of corrugated iron roofing in a day.

Building Papers and Felts.—The cheapest grade of building paper is "rosin-sized" paper. It is not waterproof, and should not be used on roofs, or on walls in a damp climate. It comes in rolls 36 ins. wide, containing 500 sq. ft., weighing 18 to 40 lbs., and costs about 3 cts. per lb.

There are a number of different kinds of waterproof papers used for sheathing under siding or shingles. P. & B. building paper, for example, is coated with a paraffin compound. It comes in rolls 36 ins. wide containing 1,000 sq. ft. The weights per roll are:

Ply	1-ply.	2-ply.	3-ply.	4-ply.
Weight	30 lbs.	40 lbs.	65 lbs.	80 lbs.

Price is 10 cts. per lb.

Common dry felts are made of wood fibers cemented together with rosin. They weigh about 5 lbs. per 100 sq. ft. The best grades of dry felt are made of wool, and weigh 11 lbs. per 100 sq. ft. when they are $\frac{1}{8}$ -in. thick, but some brands are 50% heavier than this. The price of dry wool felt is about $2\frac{1}{4}$ cts. per lb.

Tar felt, or common roofing felt, is made by saturating common dry felt with coal tar. The weight of a single layer or ply is 12, 15 or 20 lbs. per 100 sq. ft., but the felt is laid in several layers, usually 4 or 5-ply, in making a roof, each layer being mopped with a "composition" of $\frac{1}{2}$ tar and $\frac{3}{4}$ pitch. The price of tar felt is about $1\frac{1}{2}$ cts. per lb.

There are many kinds of patent roofing felts. Ordinarily they come in rolls 29 ins. wide, and each roll covers a square, allowing 2 ins. for the lap. Nails and cement are supplied with each roll by the manufacturers. The cost of the roofing is \$3 to \$5 per square, and the cost of laying it is about 1 hr. labor per square, or 40 cts. The weight of such roofing varies considerably, but ordinarily is about 100 lbs. per 100 sq. ft.

Cost of Gravel Roofs.—Tar felt, 4 or 5-ply, is first laid, the sheets being mopped with "composition" of $\frac{1}{2}$ tar and $\frac{3}{4}$ pitch. Screened roofing gravel is spread over the roof. A square of gravel roof costs about as follows:

	Per square.
1-5 cu. yd. (450 lbs.) gravel, at \$2.40.....	\$0.40
40 lbs. tar, at $1\frac{1}{2}$ cts.....	0.60
80 lbs. pitch, at $1\frac{1}{2}$ cts.....	1.20
100 sq. ft. felt, 4-ply, 75 lbs., at $1\frac{1}{2}$ cts.....	1.12
Labor, at 35 cts. per hr.....	0.70
Total per 100 sq. ft.....	\$4.02

Note.—About 20 lbs. of "composition" per square per ply is ordinarily sufficient where sheets are mopped only at the joints instead of all over; but in the above the sheets are assumed to be mopped all over, which takes 50% more composition.

Tar is usually sold by the gallon, or by the oil barrel holding 50 gallons, present prices being 12 cts. per gallon. Tar weighs almost exactly as much as water, or $8\frac{1}{2}$ lbs. per gallon.

Cost of Slate Roofs.—Roofing slate comes in a great variety of sizes, the most common of which are 18 x 8, 18 x 10, and 18 x 9 in., but sizes as large as 25 x 14, and as small as 12 x 6, are made. To determine the number of pieces to a square, deduct 3 in. from the length (for the lap), divide this by 2, multiply by the width of the slate, and divide the result into 14,000. An 18 x 9 slate would be estimated thus: $18 - 3 = 15$, which divided by 2 gives $7\frac{1}{2}$; then $7\frac{1}{2} \times 9 = 67\frac{1}{2}$; then $14,000 \div 67\frac{1}{2} = 214$ pieces.

Slates are sold by the square, that is a sufficient number of slates to lay 100 sq. ft., each course having a lap of 3 in. over the head of those in the second course below. The price f. o. b. Pennsylvania and Vermont quarries varies according to the grade; but a good No. 1 slate, $\frac{3}{16}$ -in. thick, can be bought for \$5 per square. The freight from Pennsylvania or Vermont to the Mississippi River is about \$2.50 per square. Allow about 1% waste, unless the roof is perfectly plain.

The weight of 1 sq. ft. of slate $\frac{1}{4}$ -in. thick is 3.6 lbs. As there are 214 pieces of 18 x 9-in. slate per square of roof; and if it were all $\frac{1}{4}$ -in. thick, the weight would be 868 lbs.; if it were $\frac{3}{16}$ -in. thick, the weight would be 621 lbs.

Before laying the slate, the roof is covered with paper. A 50-lb. roll will cover 400 sq. ft., and with wages at 40 cts. per hr., the cost of laying the paper is 20 cts. per square. The holes for the nails must be punched in the slate before laying. This may be done by the manufacturers, but it is usually done by hand by the slaters, because if a corner is broken off in transport the slate can be turned end for end, moreover as slate usually comes in three thicknesses it must be sorted anyway before laying, and the punching can as well be done at the same time. One slater, at 40 cts. per hr., with a helper, at 20 cts. per hr., will punch the holes in 10 x 16-in. slates at a cost of 45 cts. per square.

In laying slates, about one laborer is required for two slaters on plain roofs. A slater will punch and lay 3 squares per 8 hrs. on plain straight work, 2 squares on roofs with many hips and valleys, and as low as 1 square on difficult tower work. For fair average work allow $2\frac{1}{2}$ squares per day per slater, and allow 1 laborer to 2 slaters. This includes punching, and laying paper and slate. The cost of a slate roof, 10 x 16-in. slates, was as follows:

	Per square.
Slate for 1 square.....	\$ 5.00
Freight (650 lbs.).....	2.50
Loading and hauling.....	0.20
Wastage, 1% of \$7.70.....	0.08
16 lbs. paper.....	0.50
1 lb. nails.....	0.05
$2\frac{1}{2}$ lbs. of 3d galv nails for slate.....	0.10
Slater, at 40 cts. per hr.....	1.30
Helper, at 20 cts. per hr.....	0.30
Total per square.....	\$10.03

Cost of Roofs.—In the Proceedings Assoc. Ry. Supts. of Bridges and Buildings, 1902, a committee report gives the following costs of roofs in New England.

	Per square.
Slate	\$ 9.00 to \$12.00
Tile	30.00 to 33.00
Cedar shingles	4.50 to 5.00
Tinned shingles.....	5.00 to 6.50
Sheet tin.....	6.50 to 8.00
Tar and gravel.....	4.00 to 5.00
Ruberoid	2.75 to 3.75
Paroid	3.00 to 3.50
Tar paper, two-ply, laid double.....	2.00 to 2.25
Tar paper, three-ply, laid single.....	1.50 to 2.00

Instances were cited of slate roofs 40 years old. Shingle roofs 28 years old were cited, but 15 years seemed to be the ordinary life of good shingles. Tar and gravel roofs 30 years old were cited, but an ordinary life seemed to be 12 to 18 years.

Cost of Ferrolnclave Roof.—This type of roof was invented by Mr. Alexander Brown, vice-president of the Brown Hoisting Mch. Co. It consists of corrugated sheet steel plastered on both sides with Portland cement mortar, giving a total thickness of $1\frac{1}{4}$ in. The corrugations are in the form of a dovetail. The steel sheets are laid on purlins spaced 4 ft. 10 in., and clipped to them. The cement mortar is mixed 1-2, and that used on the under side contains a small amount of lime and hair. When the cement has set for 10 days, the upper side is painted with two coats special paint.

The cost per square (100 sq. ft.) is said to be as follows:

	Per sq.
Ferrolnclave sheets	\$ 8.50
Fastening clips.....	0.48
Laying Ferrolnclave	1.25
Cement mortar on upper side.....	3.80
Cement mortar on lower side.....	4.00
Waterproofing paint.....	1.50
Sundries, freight, supt., etc.....	1.27
Total	\$21.00

The weight is about 15 lbs. per sq. ft.

Brick Masonry Data.—The size of common bricks varies widely. I have seen bricks as small as $2 \times 2\frac{1}{4} \times 7\frac{1}{2}$ in. used for house building in New York City. In the New England States, common bricks are said to average about $2\frac{1}{4} \times 3\frac{3}{4} \times 7\frac{3}{4}$ in. In most of the Western States, common bricks average $2\frac{1}{2} \times 4\frac{1}{2} \times 8\frac{1}{2}$ in. The size of individual bricks in a car load often varies considerably; hard bricks being $\frac{1}{8}$ to $\frac{3}{16}$ -in. smaller than soft (or salmon) bricks. Pressed or face bricks are quite uniformly $2\frac{1}{4} \times 4\frac{1}{2} \times 8\frac{1}{2}$ in. A thousand bricks, averaging $2\frac{1}{4} \times 4 \times 8\frac{1}{4}$ in. weigh 5,400 lbs., if there is any standard size it may be said to be $2\frac{1}{4} \times 4 \times 8\frac{1}{4}$ in., and they weigh 125 lbs. per cu. ft.; and they occupy 43.2 cu. ft. of space, which is equivalent to $23\frac{1}{4}$ bricks per cu. ft., if no allowance is made for joints. If these bricks are laid in massive masonry with $\frac{1}{2}$ -in. joints, about 430 bricks will be required per

cu. yd., or 16 per cu. ft.; if laid with $\frac{3}{8}$ -in. joints, 516 bricks per cu. yd., or 19 per cu. ft.

Masons have empirical rules for estimating the number of bricks in a wall. Their rules do not give even an approximation to the actual number, or "kiln count." They often make no deductions for openings, but use a "wall measure" rule, allowing $7\frac{1}{2}$ bricks per sq. ft. (or per superficial foot) for a wall that is a "half brick thick," that is a 4-in. wall. For "one-brick" wall, that is 8 or 9 ins. thick, they estimate 15 bricks per sq. ft. For a "one-and-a-half-brick" wall (12 or 13 ins. thick), they estimate $22\frac{1}{2}$ bricks per sq. ft. This rule takes no account of the actual size of the bricks, and does not, therefore, give "kiln count," but gives "wall count." We have seen, above, that "standard size" bricks, laid with $\frac{3}{8}$ -in. mortar joints, will actually average 16 per cu. ft., as compared with $22\frac{1}{2}$ per cu. ft. "wall count."

If all the broken bricks, or "bats," were thrown away, the wastage would be about 2% with fair bricks to 5% with poor bricks, but it is not often that contractors are prohibited by inspectors from using practically all the "bats."

The cost of loading and hauling paving bricks is given on page 158, and practically the same costs apply to building bricks, except that the latter are lighter. As above stated, the "standard size" hard brick weighs about 5.4 lbs., or 2.7 tons per M., or 125 lbs. per cu. ft. Soft bricks weigh 20% less, but repressed bricks weigh 20% more per cubic foot. With wages at 15 cts. per hr., the cost of unloading cars into wagons is 30 cts. per M., and, unless a dump wagon is used, it costs another 30 cts. per M. to unload the wagons.

Cost of Laying Brick.—In building brick walls there are usually 1 to $1\frac{1}{2}$ laborers to each brick mason. The laborers mix mortar and carry mortar and bricks to the masons, using hods for the purpose. A hod holds about 18 bricks, or approximately 100 lbs. The wages of masons and hod carriers vary widely in different cities, but seldom exceed \$5 per 8-hr. day for masons and \$3 for hod carriers. Very often the masons' unions have forced up their rates of wages, but the hod carriers have not, and may receive but little more than other common laborers. With wages as just given, and one helper to each mason, the labor cost of laying should not exceed \$6 per M. for common brick, and \$10 per M. for pressed (face) brick, "kiln count" in both cases.

On a three-story brick hospital, with a carefully laid front ($\frac{1}{2}$ -in. "shoved" joints), the labor cost was \$5.50 per M., "kiln count." There were three laborers to every two masons, and wages were $17\frac{1}{2}$ cts. per hr. for laborers, and 45 cts. per hr. for masons, working 9 hrs. The cost of the masons' wages amount to \$3.50 per M., and the cost of the helpers' wages was \$2 per M. This cost was rather high, due to the number of deep flat brick arches over basement openings, and to the row-lock arches over other openings, as well as a tower and other pattering work.

In building warehouses, where the work was plain, wages being as just given, the cost was \$4 per M., "kiln count."

On several large city buildings, in which 15 to 20% of the brick masonry was pressed brick, each brick mason laid the following average number, "kiln count," per 9-hr. day:

Apartment house, 4 stories.....	1,200
Four-story fronts	1,250
Heavy walls, ground level.....	1,500
Heavy footings and warehouse basement walls.	3,200

A bricklayer should lay 400 or 500 pressed brick per 8-hr. day. If an ornamental brick front is to be laid, with molded arches, buttresses with bases and caps, etc., the labor of laying pressed brick may run as high as \$20 per M.

In veneering a frame building with brick, a mason will average 400 bricks per day.

In building brick arches to support the sidewalk in front of a city building, after the centers were set, each bricklayer averaged 1,800 bricks per 9-hr. day; and it required one man to make and deliver mortar and to deliver brick to every two bricklayers. The brick arches were 5-ft. span, 11 ft. long, and 4 in. thick.

Cost of Mortar.—With lime mortar, mixed 1 part lime to 3 parts sand, it required 0.9 bbl. lime per M. of bricks, "kiln count," the bricks being laid with $\frac{3}{8}$ -in. joints. A common allowance in estimating the cost of mortar, for "standard size" bricks, is 1 bbl. lime and 0.6 cu. yd. sand per M., "kiln count." About $\frac{1}{2}$ cu. yd. of mortar is usually allowed per cu. yd. of brick masonry, or 0.7 cu. yd. mortar per M. of bricks, when bricks are laid with $\frac{1}{2}$ -in. joints. If cement mortar is used, the number of barrels of cement per cubic yard of mortar will be found on page 253. It will seldom require less than 1 6 bbls. of cement per M. of bricks, or 0.8 bbl. per cu. yd. of brick masonry, for if the mortar is made leaner it will not trowel well, and cause more loss in labor than is saved in cement.

Rockland, Me., lime is sold by the barrel, 220 lbs. net. When shipped in bulk $2\frac{1}{2}$ bu., of 80 lbs. per bu., are usually called a barrel. A barrel holds about 3.6 cu. ft. The average yield of lime paste from the best limes is 2.6 bbls. of paste for each barrel of quick lime. This paste is usually mixed with 2 parts sand by measure. It, therefore, takes about $1\frac{1}{2}$ bbls. of the best quick lime to make 1 cu. yd. of mortar. A poor lime does not make $\frac{1}{2}$ as much paste as a good lime.

The price of lime is about 60 cts. per bbl.

Cost of Brickwork in a Railway Repair Shop.*—Below is given the labor cost of some brickwork done in October, 1896, for the Detroit, Lansing & Northern R. R. The work consisted of building the walls of the railroad repair shop at Ionia, Mich. The work was done by contract, the contractors, however, furnishing only the labor, this being done for a lump sum; the materials were furnished by the railroad company. The face bricks were new, but the back was of bricks which came from an old building. The size of the bricks was $2\frac{1}{4}$ x $3\frac{3}{4}$ x 8 in., and the joints were from $\frac{3}{8}$ -in. to $\frac{1}{2}$ -in. in thickness. According to these figures about 20 bricks were

**Engineering-Contracting*, May 16, 1906.

used to the cubic yard, and that number was used in computing the number of bricks in the building. In the summary is given the actual cubic contents of the walls, all openings being deducted.

As the walls were only 20 ft. high, scaffolds and runways were built so that wheelbarrows could be used throughout the entire work for tending masons. The cost of laborers was thus reduced. The scaffolding was built by the railroad company. The wages allowed were as follows: Foreman, 40 cts. per hr.; mason, 30 cts. per hr.; laborers, 12½ cts. per hr. The weather was favorable for good work.

Cubic ft. built.....	5,204.3
Bricks laid	104,086
Foreman, hrs.	161
Mason, hrs.	439
Laborers, hrs.	509

The average number of bricks laid per mason per hour was 173, including the time of the foreman, who was a mason and worked also.

The labor costs were as follows:

Mason's wages	\$196.10
Laborer's wages	66.63
Mason's wages per cu. yd.....	1.02
Mason's wages per M. brick.....	1.88
Laborer's wages per cu. yd.....	0.23
Laborer's wages per M. brick.....	0.61
Total cost of masons and labor per cu. yd..	1.35
Total cost of masons and labor per M.....	2.49

From the above figures the cost of labor for similar work can be estimated as follows: Labor cost of 1 cu. yd. brickwork is equal to 5/6-hour wages of foreman, plus 2¾ hours wages of mason, plus 2½ hours wages of laborer. In the same manner, the cost of laying 1,000 brick is equal to 5/6-hour wages of foreman, plus 4¼ hours wages mason, plus 4¾ hours wages laborer.

In the work it was found that 0.44 cu. yd. of sand and 10-11 bbl. (bulk) lime were required to lay 1,000 brick with ¾-in. to ½-in. joint. One barrel of lime equaled 3½ cu. ft. and weighed 201 lbs., the weight being figured from car weight. Accordingly 1 bbl. (bulk) lime was used for laying 1,100 bricks, with ¾-in. to ½-in. joint; 1 cu. yd. sand was used for laying 2,260 bricks, with ¾-in. to ½-in. joint.

Cost of Brickwork in Five Buildings for Manufacturing Plant.*—Mr. Sam W. Emerson gives the following record of cost of brickwork in five buildings forming part of a large manufacturing plant. The work was done by the owners hiring their own labor.

All joints in the brickwork were struck both sides, and a first-class job obtained.

On building No. 1 local bricklayers were used at 50 cts. per hour, but for the other buildings city bricklayers at 60 cts. per hour were imported. The latter did better work and more of it, as shown by Table VII.

**Engineering-Contracting*, April, 1906, p. 100.

The hod carriers were developed from local laborers, and were paid 17½ cts. per hour.

Buildings Nos. 1 and 2 were long and low, containing about equal amounts of 9-in. and 13-in. wall.

Buildings Nos. 3 and 4 were higher and had a somewhat larger proportion of 13-in. wall.

Part of the brickwork in No. 4 was started from steel lintels at some distance above the floor line, which explains the high cost of scaffolding.

Building No. 5 was higher and contained more brick than any of the others. It was composed of 13-in. walls, with some 17-in. and 22-in. walls. The heavier walls account in part for the lower cost of laying, but better foremanship had something to do with it.

The scaffolds were erected by carpenters at 20 and 22½ cts. per hour, drawn from other parts of the work when needed.

Handling materials include unloading and hauling brick, sand, lime and cement, and is the average for the job. About one-third of the materials had to be hauled from a switch nearly a mile away, the balance being delivered on a switch run over to the plant site.

The brick were large, so that 918 laid up a "thousand," figuring 14 brick per square foot of 9-in. wall. All openings were deducted.

Brick cost \$5.00 and \$5.25 per M., f. o. b. the yards; the average cost was \$5.08 per M.

No record was kept of the cost of scaffold lumber, as material ordered for other purposes was used and worked up later in wooden buildings.

About two or three weeks after the 60-cent bricklayers started work, the writer, being dissatisfied with the way the work was going, started the practice of preparing careful estimates of the brick laid each week and figuring the cost per 1,000 for bricklayers and helpers.

Within three weeks after the first estimate, the output per bricklayer had increased over 40 per cent, and about 30 per cent increase was maintained.

This illustrates one of the reasons for keeping "up-to-date" cost records.

The cost of the work per 1,000 brick was as follows:

TABLE VII.—LABOR COST PER 1,000 BRICK.

Buildings—Nos.	1.	2.	3.	4.	5.	Av.
Bricklayers,† 60 cts. per hr..	\$5.56	\$4.49	\$4.57	\$4.68	\$3.68	\$4.16
Helpers,* 17½ cts. per hr..	1.95	1.67	2.14	1.95	2.00	1.87
Carpenters,‡ 20 and 22½ cts.	.70	.71	.88	1.15	.67	.77
Handling materials	1.16	1.16	1.16	1.16	1.16	1.16
Total labor	\$9.37	\$8.03	\$8.76	\$8.94	\$7.61	\$7.96

*Hod carriers and mortar men.

†On Building No. 1 bricklayers received 50 cts. per hr.

‡Engaged in building scaffolds.

Note.—Buildings Nos. 1 and 2 were long and low, with about equal amounts of 9-in. and 13-in. walls; Buildings Nos. 3 and 4 had larger proportion of 13-in. wall; Building No. 5 contained more brick than any of the others, and had 13-in. walls, with some 17-in. and 22-in. walls.

COST PER 1,000 BRICK.

<i>Materials:</i>	
Brick, \$18, at \$5.08.....	\$ 4.67
Brick, freight	1 12
Sand, $\frac{1}{2}$ cu. yd., at \$0.46.....	0.23
Sand, freight	0.13
Cement, 0.44 bbl., at \$.....	0.88
Lime, 2 bu., at \$0.20.....	0.40
Total, materials.....	\$ 7.43
Total, labor (average).....	7 96
Grand total, material and labor, per 1,000 brick	
	\$15.39

As is stated elsewhere in this article, 14 brick were figured as making one square foot of 9-in. wall. This would make 604 bricks, wall measure, per cubic yard. Accordingly, if we divide the figures in the tabulations given above by 2, we will have the cost per cubic yard of brick masonry. On this basis we have:

<i>Materials:</i>	Cost per cu. yd.
459 bricks, at \$5.08.....	\$2.33
Freight56
$\frac{1}{4}$ cu. yd. sand, at \$0.46.....	.11
Freight06
.22 bbl. cement, at \$2.00.....	.44
1 bu. lime, at \$0.20.....	.20
Total, materials	\$3.71
<i>Labor:</i>	
Bricklayers	\$2.08
Helpers93
Carpenters39
Handling materials58
Total, labor	\$3.98
Total, material and labor.....	\$7.69

Cost of Brick Chimneys.—On small chimneys and fireplaces the labor costs 2 to 3 times as much per M. as on plain wall work. A mason (55 cts. per hr.) and helper will lay 600 bricks in 9 hrs. The labor costs 30 to 35 cts. per lin. ft. for single-flue chimneys, 8 x 8 ins. square and 4 ins. thick; and 50 cts. per lin. ft. for double-flue chimney. There is a wastage of brick of about 5% where the brick fit, or 10% where cutting is necessary.

Cost of High Brick Chimney Stacks.—With wages of masons at 55 cts. per hr., and where the flue is large enough for men to work from the inside, the cost of laying bricks for chimney stacks, 100 to 125 ft. high, is \$12 per M. of bricks. In one case a stack 150 ft. high, containing 250,000 bricks, cost \$7 per M. for labor, wages being as above given.

Cost of Brickwork, Cross-References.—In various sections of this book will be found further data on brick masonry, for which consult the index under "Brickwork."

Cost of Rubble Walls.—Basement walls are commonly made of rubble. The best work requires "two-man rubble," that is, stone too heavy for one man to lift. A common allowance for a lime-

stone rubble wall is $\frac{1}{4}$ cu. yd. sand, $\frac{1}{2}$ bbl. cement, and 2,800 lbs. stone, per cu. yd. of wall. If lime is used, allow $\frac{1}{2}$ bbl. lime. A mason and helper will lay 3 cu. yds. in 8 hrs., so that if wages are 60 cts. per hr. for mason and 25 cts. per hr. for helper, the cost of laying is \$2 per cu. yd.

For further data, see the sections on Masonry and Concrete.

Cost of Ashlar.—Ashlar in buildings is estimated by the cubic foot. In ordering "raw stone" (uncut stone) for ashlar, give the quarryman the exact number of cubic feet measured in the wall. He will make allowance for the waste in cutting it.

The cost of Bedford ashlar for the moldings, turrets, etc., in an Omaha building was:

	Per cu. ft.
Raw Bedford	\$0.65
Cutting, wages 55 cts. per hr.	1.00
Setting in the building	0.20
Washing and pointing	0.05
Total in place	\$1.90

It requires about 1 gal. muriatic acid to wash 500 sq. ft. To wash and point the joints costs 3 cts. per sq. ft.

Cost of Cut Stone Work.*—The walls for the building of the Government Printing Office at Washington, D. C., completed in 1902, were built of red bricks trimmed with red sandstone from a quarry near Longmeadow, Mass. The cost of this stone, ready to set, was as follows:

	Per cu. ft.
Plain ashlar	\$1.90-\$2.00
Molded courses	2.00- 2.40
Sills	3.00- 2.40
Lintels	1.95- 2.15
Columns ..	3.00

In computing these prices, all molded and curved or irregular pieces were squared out to the minimum containing rectangular parallelepipedon. The cost of setting, etc., average for all classes, was as follows:

	Per cu. ft.
Handling	\$0.123
Setting179
Cutting (corrections, etc.)018
Pointing041
Mortar012
Miscellaneous materials026
Total	\$0.409

The high cost is said to be due to the care with which the joints were caulked, and to the fact that there was not enough stone to be placed to justify the purchase of a special plant to handle it. Some of the wages paid for 8-hr. day on this job were as follows: Laborers, \$1.50; stone masons, \$4; stone cutters, \$4.

**Engineering-Contracting*, Feb. 19, 1902.

Cost of Wood Lathing.—The standard size of wood laths is $\frac{1}{2}$ -in. \times $1\frac{1}{2}$ in. \times 4 ft. There is a special lath made 32 in. in length. Laths are sold by the 1,000 in bundles of 50 or 100 laths per bundle. A common price is \$3 per 1,000 laths. It requires 1,500 standard laths to cover 100 sq. yds. Allow 10 lbs. of 3d fine nails for 100 sq. yds. when joists are 16 in. center to center. Chicago lathers have fixed 1,250 laths as a day's work per man.

The cost per 100 sq. yds. is as follows:

	100 sq. yds.
1,500 laths, at \$3 per M.....	\$4.50
10 lbs. nails, at 3 cts.....	0.30
Labor, at \$3.20 per 8-hr. day.....	3.84
Total per 100 sq. yds.....	\$8.64

This is 8.6 cts. per sq. yd. There is no uniformity in practice as to deducting window and door openings from the area lathed.

Cost of Metal Lathing.—There are several makes of wire lathing, as well as expanded metal lathing. For plastering, the Expanded Metal Engineering Co., of New York, furnish two styles of expanded metal lath, in sheets $1\frac{1}{2}$ \times 8 ft., as follows.

	Lbs. per sq. yd.
"Diamond" lath, Gage No. 24.....	3.65
"Diamond" lath, Gage No. 26.....	2.66
"A" lath, Gage No. 24.....	4.23
"B" lath, Gage No. 27.....	2.84

The price of these laths ranges from 15 cts. to 20 cts. per sq. yd.

The cost per 100 sq. yds. is as follows:

	100 sq. yds.
100 sq. yds., "Diamond" No. 26.....	\$16.00
10 lbs. staples, at 3 cts.....	0.30
Labor, at \$3.20 per 8-hr. day.....	3.20
Total per 100 sq. yds.....	\$19.50

This labor includes the cost of scaffolding, and is based upon some 6,000 sq. yds. of work. It will be noted that the labor cost is 1.2 cts. per lb. of metal.

Cost of Plaster.—Plastering on laths generally requires three coats, occasionally two coats. The first is the scratch coat; the second is the brown coat; the third is the white coat, or finish. On brick walls the scratch coat is generally omitted.

Plaster is made either with lime or with cement plaster. Cement plaster (or wall plaster) usually consists principally of plaster of Paris. Some plasters are made of lime gaged with Portland cement. Whatever kind of lime or plaster is used, sand and hair are mixed with the plaster. The hair is put up in paper bags supposed to contain 1 bu. of hair when beaten up, and supposed to weigh about 7 lbs. Some cement plasters are sold with the proper amount of hair mixed in. Cement plaster is commonly sold in 100-lb. sacks, four sacks making 1 bbl. A common price is 25 cts. per sack.

In making lime plaster, 1 part of lime paste to 2 or 2½ parts of screened sand is used. About 1½ cu. yds. of sand are required per 100 sq. yds. of three-coat plaster, and about 4 bbls. of lime, or cement plaster, and 2 bu. of hair.

The cost of 100 sq. yds. of three-coat plaster is about as follows:

	100 sq. yds.
1.75 cu. yds. sand, at \$1.....	\$ 1.75
3½ bbls. lime, or 9 bu., at 36 cts.....	3.15
2 bu. hair, at 40 cts.....	0.80
100 lbs. plaster of Paris, at 50 cts.....	0.50
Labor, plasterers, at 55 cts. per hr.....	15.00

Total, 100 sq. yds., at 21.2 cts.....\$21.20

Cost of Plastering.—Mr. R. L. Brooker gives the following average cost of plastering 17 houses in Ohio in 1902. Each house required 500 to 1,000 sq. yds. of plastering.

	Per sq. yd.
	Cts.
Lath and nails.....	6.5
Labor lathing.....	3.0
Materials for 1st coat mortar.....	3.5
Labor for 1st coat mortar.....	3.8
Materials for white coat.....	1.0
Labor for white coat.....	3.0

Total20.8

The following materials were required per 100 sq. yds.:

26 bunches of lath.

7 sacks Alabastine (100 lbs. ea.), mixed 1:2.

150 lbs. white coat material (white enamel finish).

In plastering, a man averaged 16 sq. yds. of first coat per hour, although on two jobs the average was 21 sq. yds. per hr. On white coat work, a man averaged 19 sq. yds. per hr., and the best record was 21½ sq. yds. per hr.

The lowest labor cost of lathing was 2¼ cts. per sq. yd.

The plastering was "three-coat" work, the first and second coat being applied at the same time and of the same material, while the third or white coat was not applied till the other coats were dry. The "brown wall" was rodged along angles and base, then darbled, and just before taking a set was floated to an even surface.

Cost of Placing Tile Fireproofing.—Hollow tile used for floors or walls, or for protecting steel beams and columns, is measured by the square foot. It is desirable to purchase it from the manufacturers on the basis of the square foot measured in the work. Where the brick-layers' wages were 45 cts. per hr., the tile work in a four-story hospital cost 5½ cts. per sq. ft. for the labor on the 10-in. and 12-in. tile floors and roof. This does not include the cost of hauling the tile to the building, but it does include the hoisting and delivery of the tile to the mason. The labor cost of 4-in. tile partitions and tile protection for I-beams and columns was 4½ cts. per sq. ft.

Cost of Terra Cotta Brick Fire Proofing.*—Solid brick of porous terra cotta were used for fireproofing the floor arches, girders and column coverings at the U. S. Government printing office, completed in 1903, at Washington, D. C. In connection with the floor arches a very heavy skewback having projecting flanges $1\frac{1}{2}$ ins. thick was designed. The protecting flanges are very heavy and strong, and meet, with a small mortar joint, under the beam. The lower flanges or girders were covered with shoes of the ordinary form, meeting under the girder. They were, however, much heavier than ordinarily used, being solid and $2\frac{1}{2}$ ins. thick. They were filled with mortar and squeezed on, so as to have a solid bearing, and were then wrapped all around with wire lathing and plastered with Portland cement mortar. On top of the shoes, on either side of the girder, was built a 4-in. terra cotta brick wall, the wire lathing being applied before the 4 ins. walls were built. The 4 ins. walls on the sides of the girder were carried to the top flange before the floor arches were built. The latter were then built, abutting at their ends against the upper part of the 4-in. walls, thus bracing them securely in position. The columns were covered with 4-ins. of porous terra cotta brick work built around them. The inside of the column and all space between it and the fire proofing were filled solid with Portland cement concrete. The work was done by contract, the following data being obtained by keeping records of the contractors' work:

From time required to set, it was determined that the girder shoes on the various girders were equivalent to about 8.5 bricks per linear foot. This was a little high for beams smaller than 20 ins., but it was compensated for by increased cost of changing scaffolds, centers, etc., for the smaller girders. The figures of cost do not allow for power for hoisting furnished by the United States, nor for contractor's general expense.

GIRDER COVERINGS OF 23-IN., 30-IN. AND 24-IN. GIRDERS.

Total labor cost:

Per 1,000 bricks.....	\$12.80
Per linear foot of covering.....	0.524

Materials, exclusive of the terra cotta and wire netting:

Per 1,000 bricks.....	0.85
Per linear foot of covering.....	0.162
Average day's work per man, bricks.....	564
Number of bricks per barrel of cement.....	546

GIRDER COVERINGS FOR GIRDERS 20 INS. AND UNDER.

Labor cost:

Per 1,000 bricks.....	\$12.80
Per linear foot of covering.....	0.323

Materials, exclusive of terra cotta and wire netting:

Per 1,000 bricks.....	3.40
Per linear foot of covering.....	0.093
Average day's work per man, bricks.....	564
Average number of bricks per barrel of cement.....	616

*Engineering-Contracting, Dec. 4, 1907.

COLUMN COVERINGS.

Labor Cost:

Per 1,000 bricks.....	\$12.30
Per linear foot of covering.....	0.40
Average day's work per man, bricks.....	564
Average number of bricks per barrel of cement...	545

In the one linear foot of beam covering (skewbacks) was taken as equivalent to 5.5 bricks in time and labor, data on the work being as follows:

Total labor, per 1,000 bricks.....	\$10.44
Total labor per sq. ft. of floor.....	0.06
Total materials, except bricks, per 1,000 bricks..	3.65
Total materials, except bricks, per sq. ft. of floor.	0.021
Average day's work per man, bricks.....	892
Average number of bricks per barrel of cement...	575

The above figures are based on the actual number of bricks laid plus 3 per cent for waste. The average cost of all fireproof construction, excluding ceilings, but including column and girder coverings, and including roof, was 36.4 cts. per square foot, of which 9.5 cts. was labor applied at the building. Some of the wages in force on the work were as follows per 8-hr. day: Laborers, \$1.50 to \$2; bricklayers, \$4 to \$4.50.

Cost of Ornamental Terra Cotta Work.*—In the construction of the new U. S. Government printing office at Washington, completed in 1903, 19,100 cu. ft. or 585 tons of ornamental terra cotta was used. All of the ornamental terra cotta was filled solid with concrete and where it projected considerably, as in the main cornice, it was thoroughly tied back with steel anchors. The ornamental terra cotta used was built up of relatively thin webs, like hollow tiles, except that it was built up by hand instead of by being forced through a die. The total cost of the work was as follows; the price given for materials, however, does not include brick or concrete filling:

	Per cu. ft.	Per ton.
Handling	\$0.0322	\$1.0881
Setting1301	4.3513
Cement, etc.0243	.7944
Anchors, etc.0245	.8010
Total cost of setting.....	\$0.2121	\$6.9348
Average price for materials.....	1.5300	50.0000
Grand total	\$1.7421	\$56.9348

Some of the wages paid per 8-hr. day during the construction of the building were as follows: Laborers, \$1.50; bricklayers, \$4 to \$4.50.

Cost of Combined Concrete and Tile Floor Construction.†—Reinforced concrete was employed in constructing, during 1908, a 150x50 ft. extension from 8 to 10 stories high to the famous Quebec hotel, the Chateau Frontenac. Structurally the new building consists of a reinforced concrete skeleton covered with brick outside walls, metal roof, etc. The floors were combined clay tile and reinforced concrete con-

**Engineering-Contracting*, Nov. 20, 1907.

†*Engineering-Contracting*, Aug. 18, 1909.

struction, and columns and girders were of reinforced concrete. Complete records of the cost of the work were kept, but these are not available for publication except for one typical floor, and the cost of this floor is given below.

The typical floor is that located at elevation 187. The slab spans varied from 12 to 16 ft. The tile used were 8 x 12-in. hard terra cotta. The concrete joists were 4 ins. wide, reinforced by one $\frac{3}{4}$ x 2-in. Kahn bar and one $\frac{1}{2}$ -in. cup bar. The joists extended the full depth of the tile and were in one piece, with the 2-in. concrete slab which covered the tile. The floor concrete was a 1-2-4 mixture, and the column concrete was a 1-1-2 mixture. A $\frac{3}{4}$ -in. limestone was used for aggregate. The concrete was machine mixed at basement level and was hoisted to floor level, discharged into a hopper and distributed over the floor by wheelbarrows. The quantities required for the floor were:

Concrete in columns, cu. yds.....	43.6
Concrete in floor, cu. yds.....	255.8
Reinforcing steel, tons.....	29.9
Tile, 8 x 12-in., number.....	28,000
Lumber, forms and staging, ft. B. M.....	45,000

The cost of the floor concrete was as follows:

Concrete:	Total.	Per cu. yd.
Materials for 255.8 cu. yds.....	\$1,445	\$5.65
Placing 255.8 cu. yds.....	174	0.58
Totals	\$1,619	\$6.23

This is the cost for the floor slabs and beams above. The cost of the concrete in the columns (43.6 cu. yds.) was \$464, or \$9.21 per cu. yd. The cost of reinforcement for the whole floor, columns included, was as follows:

Reinforcement:	Total.	Per ton.
29.9 tons steel at \$75.....	\$1,943	\$75.00
Cartage on steel.....	21	0.80
Handling and placing steel.....	130	5.00
Totals	\$2,094	\$80.80

This gives a cost per cubic yard of concrete for reinforcement of \$6.99—or say \$7. The cost of forms and staging was as follows:

Forms and Staging:	Total.	Per M. ft.
45 M. ft. B. M. lumber at \$22.....	\$990	\$22.00
Construction	616	13.70
Totals	\$1,606	\$35.70

Summarizing, we get the following total cost for concrete, charging everything, except tile work, to concrete:

Item:	Per cu. yd.
Concrete in place.	\$6.97
Reinforcement	6.99
Forms and staging.....	5.38
Total	\$19.34

The cost of the tile work in the floor slabs was as follows:

<i>Tile Work:</i>	<i>Total.</i>	<i>Per tile.</i>
28,000 tile at 10 cts.....	\$280	10.00 cts.
Cartage	33	0.12 cts.
Handling and laying.....	42	0.15 cts.
Totals	\$355	10.27 cts.

The total cost of the floor was \$6,672, divided into the following percentage items:

Concrete	33 per cent
Steel	35 per cent
Forms	26 per cent
Tile	6 per cent
Total	100 per cent

Costs of Combination Concrete and Tile Floors in Three Buildings.*—The following figures of costs of similar construction are from figures given by Prof. W. K. Hatt, Purdue University, Lafayette, Ind., who was engineer of the work. The work comprised three buildings:

Indiana State Soldiers' Home.—This building is irregular in plan, with two stories, attic and basement. It is constructed of brick and limestone, with reinforced concrete hollow tile floors, each floor covering approximately 7,000 sq. ft. The floor ribs are 4 ins. in width and range in depth from 10 to 6 ins. The rib spans are from 8 to 15 ft. The tile are 12 X 12 ins. of projected area, and the ribs are thus spaced 16 ins. centers in all cases. The thickness of concrete over the tile is 2 ins. Upon this floor is placed a 3-in. cinder concrete, over which there is a $\frac{3}{8}$ -in. maple flooring upon nailing strips. The floor was designed to hold a live load of 60 lbs. per sq. ft. for the first floor and second floor, and 30 lbs. per sq. ft. live load for the attic floor in addition to cinder filling and wood floor. The ribs were continuous from the side rooms through into the corridor. The concrete was 1:2:4, with a screened gravel aggregate. The gravel and sand contained about $4\frac{1}{2}$ per cent of clay. Reinforcing was plain, round bars of soft steel. Forms consisted of $\frac{3}{8}$ -in. lagging supported on joists, spaced 24 ins., running between the walls. The steel rods were supported on a large-headed nail driven into the centering, and the wire staple was driven over the bar into the same centering. The channels of the ribs were cleaned of all dirt by blowing out with steam. The tile were kept wet.

The attic floor was of cinder concrete slab construction, 3 ins. thick. Wire fabric of 3 X 12-in. mesh, 3 X 8-in. and Nos. 6 and 10 gage wires, respectively, were used for reinforcing. The cinder concrete was 1:2:4. Cinder was of good quality and screened of all ashes.

Most of the floor construction was during freezing weather and the building was heated. Salamanders were kept burning day and night and the forms were sprinkled to prevent baking the con-

**Engineering-Contracting*, Oct. 18, 1909.

crete, while the exposed surface of the concrete was protected from freezing by tar paper, on which was a layer of manure.

Table VIII. gives the unit cost of the second floor of the Soldiers' Home Hospital. The spans were as follows: Corridor, clear span, 8 ft.; side rooms, clear span, from 10 to 15 ft.

The unit stresses used for the design were as follows: Tension of steel, 16,000 lbs. per sq. in.; compression in concrete, 750 lbs. per sq. in.; bond, 75 lbs. per sq. in.; diagonal tension, 75 lbs. per sq. in. (one bent rod).

Totals	\$1,829.93	\$0.190	\$17.24

Purdue University Experiment Station Building.—The building is U-shaped, with basement, two stories and attic. The first and second floors were designed for a live load of 100 lbs. per sq. ft., and the attic for a live load of 60 lbs. per sq. ft., in addition to weight of cinder filling and floor. The concrete is 1:2:4; aggregate was screened bank gravel. The sand and pebbles were remixed in specified proportion. Reinforcing was plain, round bars of steel. The floors were supported on girders and columns. The spans varied from 9 to 23 ft.

The centering is composed of 4 × 4-in. posts with 2 × 10-in. chords nailed to them. Upon the chords are joists supporting ¾-in. lagging. The spacing of the chords, posts and joists varied accord-

ing to the weight of the floor supported. On the lagging tiles are placed with a clearance of not less than 4 ins. from all walls and girders and spaced 17 ins. centers, thus making a 5-in. rib. In laying these tile, hard-burned, small tile were placed together, and soft-burned, large tile together, thus assuring a rib of even width. The

rods were held in place by nails and staples and were continuous from one panel to another. Before any concrete was deposited in the ribs a 1:3 cement mortar was placed in the bottom of the channel and brought to the level of the middle of the rod. Great care was exercised in cutting the concrete in between the rods and against the faces of the tile. The concrete was very wet, so that it would keep an even surface in the wheelbarrow, but yet would support the pebbles on the surface.

A batch of concrete in the mixer was received in a bucket and hoisted to a large box on the floor, and taken out in barrows to be dumped.

The first floor was laid during freezing weather. To prevent freezing, salamanders were kept burning day and night and the concrete was covered with a heavy layer of straw.

The labor for the concrete was paid at a rate of 20 cts. an hour. The unit cost for the first and second floors of the experiment station are given by Tables IX and X, as furnished by H. A. Wortham, inspector on the work. Note that these floors cost on an average of about 30 cts. per square foot.

The unit stresses used were as follows: Tension in steel, 16,000 lbs. per sq. in.; compression in concrete, 750 lbs. per sq. in.; bond on steel, 75 lbs. per sq. in.; diagonal tension without stirrups, but with one bent rod, 75 lbs. per sq. in.

The external moments were figured $\frac{1}{8}$ W. L., both at the center and over supports. The length of span was between centers of the bearings. This design is conservative, and, in the belief of the writer, might be cut down perhaps 25 per cent with safety.

Shrinkage stresses at the surface of the floors are taken up by $\frac{1}{8}$ -in. wire.

Cost of Bituminous Concrete for a Mill Floor.*—In laying tar

*Engineering-Contracting, Aug. 14, 1907.

concrete base for wood covered mill floors, the common practice is to use a mixture of steam cinders aggregate and coal tar binder, and to mix the materials by hand. A departure from this practice is recorded by Mr. C. H. Chadsey, Construction Engineer, Northern Aluminum Co., Ltd., Shawinigan Falls, P. Q., Canada, in laying 17,784 sq. ft. of mill floor. A sand, broken stone and tar mixture was used and the mixing was done with a Ransome mixer. The apparatus used and the mode of procedure followed were as follows:

Two parallel 8-in. brick walls 26 ft. long were built 4 ft. apart and 2½ ft. high to form a furnace. On these walls at one end was set a 4x6x2 ft. steel plate tar heating tank. Next to this tank for a space of 4x8 ft. the walls were spanned between with steel plates. This area was used for heating sand. Another space of 4x8 ft. was covered with 1½ in. steel rods arranged to form a grid, this space was used for heating the broken stones. The grid proved especially efficient, as it permitted the hot air to pass up through the stones, while a small cleaning door at the ground allowed the screenings which dropped through the grid to be raked out and added to the mixture. A fire from barrel staves and refuse wood built under the tank end was sufficient to heat the tar, sand and stone.

For mixing the materials a Ransome mixer was selected for the reason that heat could be supplied to the exterior of the drum by building a wood fire underneath. This fire was maintained to prevent the mixture from adhering to the mixing blades, and it proved quite effective, though occasionally they would have to be cleaned with a chisel bar, particularly when this aggregate was not sufficiently heated before being admitted to the mixture. A little "dead oil" applied to the discharge chute and to the shovels, wheelbarrows and other tools effectually prevented the concrete from adhering to them.

The method of depositing the concrete was practically the same as that used in laying cement sidewalks. Wood strips attached to stakes driven into the ground provided templates for gaging the thickness of the base and for leveling off the surface. The wood covering consisted of a layer of 2-in. planks, covered by matched hardwood flooring. In placing the planking, the base was covered with a ¼-in. layer of hot pitch, into which the planks were pressed immediately, the last plank laid being toe-nailed to the preceding plank just enough to keep the joint tight. After a few minutes the planks adhered so firmly to the base that they could be removed only with difficulty. The hardwood surface was put on in the usual manner.

The prices of materials and wages for the work were as follows:

Pitch, bulk, per lb.....	\$ 0.0075
Gravel per cu. yd.....	1.50
Spruce sub-floor, per M. ft. B. M.....	15.00
Hardwood surface, per M. ft. B. M.....	31.00
Laborers per 10-hour day.....	1.50
Foreman, per 10-hour day.....	4.00
Carpenters, per 10-hour day.....	2.00

At these prices and not including a small administration cost or the cost of tools and plant, the cost of the floor consisting of 4½ ins. of concrete, 2 ins. of spruce sub-flooring and ¾ in. hardwood finish was as follows:

	Per sq. ft.
Pitch	\$0.04
Gravel	0.02
Spruce, for sub-floor.....	0.03
Hardwood for surfacing.....	0.036
Labor, mixing.....	0.03
Labor, laying.....	0.015
Carpenter work.....	0.025
Total per sq. ft.....	\$0.196

Cost of Passenger Stations.—In the *Railroad Gazette*, Sept. 16, 1904, p. 350, photographs are given of a passenger station of the Santa Fe at Oakland, Calif. It is 204 ft. long, including arcades, and 54 ft. wide, total 11,000 sq. ft., and its cost was \$12,000. The main part is two stories high. It has arcades 12 ft. wide running entirely around it. The building is Spanish mission style, built of steel lath covered with concrete and with red tile roof.

A one-story brick passenger station built in 1898 at Quincy, Ill., for the C. B. & Q. R. R., cost \$75,000, or \$4.27 per sq. ft. It is 58 x 204 ft., and has a tower, 20 ft. square at the roof level, rising to a height of 150 ft. The walls of the station are of red pressed brick, with trimmings of sandstone and terra cotta. The walls are 22 ft. high. The roof is of Spanish tile, with a pitch of 30°. The interior finish is an enameled brick wainscoting, and plastered walls and ceiling. The waiting room (54 x 70 ft.) has a marble tile floor, and the other rooms have mosaic tile floors.

Cost of Four Frame Depots*.—This is the first of a series of articles that we shall publish on the cost of railway buildings. While they are typical railway structures, still the cost data will be found equally valuable in estimating the costs of buildings erected for other purposes.

It is a fact not generally known that the labor cost of framing and erecting plain buildings averages from \$10 to \$15 per 1,000 ft. B. M. This fact will be clearly brought out in these articles, and it will be of great assistance to anyone who is called upon to estimate the cost of a plain frame building. Wages will be given in each case, but the reader is cautioned against supposing that an increase in wages necessarily involves a corresponding increase in cost. A high priced carpenter is usually more efficient than a low priced carpenter, the very fact that he is high priced often being evidence in itself that he is correspondingly more competent than the low priced man. A contractor who pays \$3.50 a day for carpenters will usually get more work done for the money than will a railway company that pays \$2.50 a day for its "company carpenters." Railways have a policy of paying very low wages, under

**Engineering-Contracting*, Aug. 28, 1907.

the mistaken idea that they are economizing thereby. In consequence, they usually secure lazy or incompetent day workers. Perhaps, with their present lack of system in keeping costs of construction, the railways would gain nothing by employing higher priced men.

The work that we are about to describe was done by "company forces," carpenters receiving \$2.50 for 10 hours. As is usually the case in day labor jobs, the men were very slow.

The method of summarizing the costs of buildings is our own. Records kept by railways are usually so jumbled up as to be of no use in comparing the costs of similar structures or in ascertaining whether the cost of any particular structure has been reasonable or not. This is largely because the engineering department is not in charge of building construction, or, if it is in charge, the engineers take little interest in work which does not seem to be engineering. There is crying need for cost analysis engineering in the management of all building construction, but particularly on railways.

The cost of these plain frame depots may be conveniently distributed under seven headings:

Lumber.
Shingles.
Millwork.
Hardware.
Paint.
Masonry.
Labor.

The first six items cover the materials. The labor item can be subdivided to suit each particular kind of work.

The weight of each building of standard design should be estimated, so that the items of freight and team haulage can be accurately predicted, but this is rarely done by railway companies.

The number of square feet of ground floor area should be stated, and the cost of each building reduced to costs per square foot, both in dollars and cents and in percentages.

Cost of a 24 x 60 Ft. Depot.—This was a small combination passenger and freight depot, of very plain design, without a masonry foundation and without plastering. The building was one story, 24x60 ft., surrounded by a wooden platform in front and ends, and a cinder platform extension.

This depot had an area of 1,440 sq. ft., exclusive of the platform.

Weight.	Lbs.
30 M. at 3,300 lbs.....	99,000
20 M. shingles at 150 lbs.....	3,000

Freight 55 tons, 200 ml., $\frac{1}{2}$ c ton mile..	\$ 55.00	
	\$952.50	
Tools (excessive in this case).....	38.50	
Grand total.....	\$990.00	
	Per. sq. ft.	Per cent.
Materials	\$0.304	44.2
Labor	0.219	46.6
Freight	0.038	6.6
Tools	0.027	4.9
Total	\$0.688	100.00

It will be noted that the price of lumber was very low.

The total labor was \$460, which is practically \$15 per 1,000 ft. B. M. in the depot and platform. If we exclude the labor of building the chimney, painting the depot and spreading the cinder platform, the labor cost \$408, or about \$13 per 1,000 ft. B. M., yet some time was lost by the crew waiting for lumber to arrive. This lost time should have been recorded, but was not.

Cost of Another 24 x 60 Ft. Depot.—This depot was similar to the last, except that 7,200 ft. B. M., of second-hand car sills (8x16 ins.), were used for posts and stringers of the platform. Grading of the depot grounds was an unusually expensive item.

Lumber.	
8,000 ft. B. M., at \$8.50.....	\$ 68.00

Labor	0.420	40.2
Freight	0.049	4.7
Tools	0.016	1.6
Grading	0.124	11.8

Total\$1.045 100.0

It will be noted that the labor on the depot, exclusive of grading the grounds, amounted to \$604. This is a trifle more than \$15.50 per 1,000 ft. B. M.

It will be noted that the paint for this depot cost four times what paint cost for the other depot, indicating the necessity of so

classifying costs as to enable comparisons to be quickly made with a view to discovering "leaks."

Cost of a 30x48 Ft. Depot.—This depot has the same area, 1,440 sq. ft., as those previously described, but is wider and shorter. The labor of building this depot cost \$542, which is equivalent to a little more than \$13 per 1,000 ft. B. M.

Cost of a 30 x 60 Ft. Depot.—This depot is of the same general type as the others, but larger, having an area of 1,800 sq. ft. It will be noted that it contains a large amount of second-hand car sills (15,200 ft. B. M.), used in building the platform. The labor cost was \$714, or nearly \$12 per 1,000 ft. B. M. The labor of painting the depot was very high. The cost of the paint was not \$20, yet the labor of painting was nearly \$70.

Cost of 57 Frame Depots.—The following data relate to a rather cheap class of railway stations built in the Pacific Northwest, by company labor. Carpenters received \$2.50 per 10. hr. day. Lumber was exceedingly cheap, hence the cost of materials is not typical. I have charged the entire cost of labor against the lumber, as that enables us to compare costs in terms of the M. ft. B. M., which is the best single unit for such comparisons.

The average cost of five, first class, combination, one-story depots (24 x 75 ft.) was as follows per depot:

	Total	Per sq. ft.
Materials	\$1,450	\$0.60
Labor	927	0.51
Total	\$2,377	\$1.33

There were 69 M. (including platforms) in each depot, hence the labor cost was \$13 per M.

The average cost of three, third class, combination, one-story depots (24 x 55 ft.) was as follows per depot:

	Total	Per sq. ft.
Materials	\$ 964	\$0.76
Labor	726	0.55
Total	\$1,690	\$1.30

There were 39 M. (including platforms) in each depot, hence the labor cost was \$18 per M.

The average cost of 18 fourth class, combination, one-story depots (16 x 48 ft.) was as follows per depot:

	Total	Per sq. ft.
Materials	\$480	\$0.63
Labor	320	0.42
Total	\$800	\$1.04

There were 20 M. (including platforms) per depot, hence the labor cost was \$16 per M.

The average cost of 15 fourth class, combination, one-story depots (16 x 68 ft.) was as follows per depot:

	Total.	Per sq. ft.
Materials	\$ 700	\$0.64
Labor	533	0.49
Total	<u>\$1,233</u>	<u>\$1.13</u>

There were 26 M. per depot, hence the average labor cost was \$20 per M.

The average cost of five, second class, combination, two-story depots (24 x 59 ft.) was as follows per depot:

	Total.	Per sq. ft.
Materials	\$1,480	\$1.04
Labor	1,150	0.81
Total	<u>\$2,630</u>	<u>\$1.85</u>

There were 71 M. per depot, hence the average labor cost was \$16 per M.

The average cost of 11 third class, combination, two-story depots (34 x 55 ft.) was as follows per depot:

	Total.	Per sq. ft.
Materials	\$1,270	\$0.96
Labor	1,000	0.77
Total	<u>\$2,270</u>	<u>\$1.73</u>

There were 51 M. per depot, hence the average labor cost was nearly \$30 per M.

The Cost of Five Frame Section Houses.*—In this issue we give the cost of five frame section houses. These were built in the northwest and were three room houses of very cheap construction, the type known in that section as "Jap houses." The work was done by company forces. As is customary for day labor work, nothing has been allowed for superintendence and general office expenses, as would have been the case if the houses had been built by contract.

The three room houses were 16x24 ft., having 384 sq. ft. of room space. The bill of material for each house was as follows:

**Engineering-Contracting*, Sept. 11, 1907.

Bill of Material for 16 x 24 Section House.

		Per sq. ft.
Materials	\$0.326	60.6
Labor	0.193	36.6
Tools	0.012	2.1
Freight	0.007	1.3
		\$0.538 100.0

It must be borne in mind that the cost of lumber is extremely low, even for the section in which this particular building work was done.

	Per sq. ft.	Per cent.
Materials	\$0.326	60
Labor	0.160	30
Tools	0.010	2
Freight	0.045	8
		\$0.541 100

Since the weight of the buildings is given in all cases, it is easy to calculate the freight for any given haul.

The average cost of the labor on these section houses was \$62 per section house. There were 7,250 ft. B. M. in each section house, and, if we charge the full cost of the labor (\$62) against this amount of lumber, we have a trifle less than \$9 per 1,000 ft. B. M.

Cost of a Blacksmith Shop, Barn and Telegraph Office.*—We give in this issue the detailed cost of erecting a blacksmith shop, a telegraph office and a barn for railroad purposes in the Northwest. The work was done by day labor. It will be noticed that the price of lumber is very low:

BLACKSMITH SHOP.

Blacksmith shop, 20 x 20 ft.; area 600 sq. ft.

<i>Weight:</i>	<i>Pounds.</i>
2,120 ft. B. M., at 3,300 lbs.....	6 296

Materials	\$0.030	40.0
Labor	0.044	60.0
Total	\$0.074	100.0

The low cost of materials for this building is explained by the fact that six-sevenths of it was second-hand material. The building had no floor, and no studs were used in the sides. The cost per M ft. B. M. for the labor on the lumber was \$12.55.

HAY BARN.

Hay barn, 20 x 35 ft.; area, 700 sq. ft.

The cost per M ft. B. M. of lumber used for labor on the office was \$15.11. This building had a floor in it and a ceiling, hence the cost per sq. ft. of area, and the cost per M ft. of lumber used would naturally be higher than in the other two buildings.

Cost of Forty Hand-Car Houses.—In this article we give the cost in detail of erecting 40 frame hand-car houses on a division of a Western railroad. The price of lumber is given and other materials, as well as the labor costs. The work was done by "company men."

Forty hand-car houses built on one division; size, 8 x 12 ft.; area, 96 sq. ft.

Total	\$0.397	100.0

The cost per M ft. B. M. for the entire labor on these buildings was \$8.62, which was quite low.

Cost of Six Tool Houses.*—In this article we give the cost in detail of building six frame tool houses for use on railroads. The labor was performed by company forces. The costs are summarized so as to allow of comparison with other cheap structures, like those that have appeared in our previous issues in this series of articles. Lists of materials and prices are given as well as wages. The cost of lumber was very low.

EXAMPLE I.

Tool house, 8 x 12 ft.; area, 96 sq. ft.

It will be noted that the labor cost about \$15 per M.

It is noteworthy in this instance to record that the foreman carpenter on this job was discharged for inefficiency, owing to the high cost of building these two sheds. One of these buildings had windows in it and shelving, which should have made the labor costs higher than in Example I, where neither windows nor shelves were used. A comparison shows that the cost per square foot of area in Example II was lower than in all the cases given except Example V. The cost was 2 1/2 cts. lower than Example I, 1 ct. of which was

in the reduced cost of labor. This makes evident the fact that cost data and their analysis form the only true way of telling of the efficiency of workmen and methods, provided the records are kept honestly and intelligently.

EXAMPLE III.

Tool house, 8 x 12 ft.; area, 96 sq. ft.

Weight:	Pounds.

It will be noted that the labor cost \$18 per M, which is excessive.

A number of these tool houses were 8 x 12, giving 96 sq. ft. of area in the building and needing for their construction a little more than a thousand feet of lumber. Their cost ran from \$28 to \$38. A comparison of these buildings with the cost of building a large number of shacks for camps in building railroads in the South will be of interest. These camps were built by one of the editors of this journal.

They were about 10 x 10, and had a slanting roof. A door made from boards was used in it, and a sliding board window was put in one side. A bunk was also built in it, but there was no floor. A thousand feet of lumber was used in building the shack. The roof was covered with tar paper, and strap hinges, hasp and padlock were used on the door. The lumber on a large number built in Tennessee cost \$10 per M; the tar paper, nails and hardware cost \$2, making a cost of materials of \$12. Carpenters were paid \$3.50 per day, and 3 carpenters completed a building in a day, making a cost of about \$10 for labor, or a total cost of \$22 per shack.

A comparison with the tool houses shows that if paint and shingles had been used these shacks would have cost a few dollars more for materials and slightly raised the cost of labor; but wages paid by the contractor on the shacks were \$1 per day higher, which about offsets the increased cost of materials.

We have pointed out before that a contractor who pays \$3.50 a day for carpenters will usually get more work for the money than will a railroad company that pays \$2.50 to its carpenters. A comparison of the cost of labor per square foot as listed above with 10 cts. per square foot as paid for these shacks shows plainly that this is true.

Capacity and Cost of Ice Houses.—The nominal capacity of an ice house is generally stated in tons of ice, and is generally taken to mean the capacity up to the eaves. By stacking the ice up higher under the roof, working from doors in the roof or gable ends, the capacity can be increased 10% or more. About 34 cu. ft. of ice make a ton of 2,000 lbs., the ice weighing 58.7 lbs. per cu. ft. It is not unusual to assume a weight of 60 lbs. per cu. ft. for convenience of calculation. Allowing for voids between the cakes of ice it is customary to allow 36 cu. ft. per ton, but this is usually too low, a fair average being nearer 40 cu. ft. per ton of 2,000 lbs. In a large, well-built ice house, only 10% of the ice is lost annually by melting and evaporation, but in smaller houses the loss is larger.

The following are dimensions and nominal capacities of some standard ice houses on the Lehigh Valley R. R.:

Size.	Capacity cu. ft.	Capacity tons.
18 X 32 ft. X 12 ft. height of frame....	6,912	150
32 X 84 ft. X 28 ft. height of frame....		1,500
30 X 120 ft. X 24 ft. height of frame....	36,400	2,000

If frame ice houses cost 5 cts. per cu. ft. to build, the equivalent cost is \$2.00 per ton of ice capacity.

Cost of Six Ice Houses.*—The work was done by railway company forces. It will be noted that the price of lumber was very low.

The labor cost per thousand feet of lumber in place was as follows:

	Per M.
Example No. I.....	\$18.00
Example No. II.....	15.80
Example No. III.....	8.70
Example No. IV.....	11.90
Example No. V.....	18.70
Example No. VI.....	10.00
Average	\$12.00

Cost of 11 Ice Houses.—The following costs relate to work done by railway company labor in the Pacific Northwest, carpenters receiving \$2.50 per 10-hr. day.

A 200-ton ice house, 22 x 31 ft., contained 18 M. The average cost of five of these houses was:

	Totals.	Per sq. ft.
Materials	\$270	\$0.40
Labor	177	0.26
Total	\$447	\$0.76

Since there were 18 M. in each house, the labor cost was \$10 per M.

A 1,000-ton ice house, 30 x 36 ft., contained 54 M. The average cost of six of these houses was:

	Total.	Per sq. ft.
Materials	\$ 470	\$0.26
Labor	500	0.20
Total	\$1,170	\$0.46

The labor cost was a little more than \$9 per M.

Cost of Car Shops.—Car shops were built in six months (1906) by contract for the Wabash Ry., at Decatur, Ill.

The total cost of the plant was \$368,000, including buildings, machinery, shop yard, grading and track.

The cost of the different buildings was as follows:

	Per cu. ft. cts.
Car shop, 88 X 464 ft.....	2.7
Blacksmith and machine shop, 80 X 294.....	3.0
Storehouse and 2-story office bldg at one end, 40 X 464.....	5.6
Wood mill, 80 X 238.....	2.9
Cabinet, upholstering, etc., shop 40 X 350.....	4.6
Power house, 60 X 108, brick.....	3.4
Lavatory building	5.4
Dry kiln, reinforced concrete roof, floor, etc.....	11.1
Dry lumber sheds.....	2.3
Iron, coal and coke sheds.....	3.5
Material sheds and racks.....	5.8

All the large shop buildings have timber frames with hollow walls formed of plaster (1 to 1½ ins. thick), on expanded metal lath (24 gage), secured to 1½-in. round rods stapled to the timbers. The shop buildings have maximum window area.

Cost of Engine Roundhouses.—Mr. R. D. Coombs gives the following bills of materials and estimated costs of wooden, of steel framed, and of reinforced concrete roundhouses. Each stall is 73 ft. long, 24 ft. wide at one end and 14 ft. wide at the other, giving an average width of 19 ft., or an area of 912 sq. ft.

The estimated cost of one stall of the wooden roundhouse with brick walls is.

WOODEN ROUNDHOUSE.

Roof and Center Columns:

330 ft. B. M. spruce monitor sheathing at \$35.00....	\$ 12.30
320 ft. B. M. pine monitor purlins at \$40.00.....	12.80

4 lifting windows at \$10.00.....	40.00
Double door	40.00

Total for walls

Total for one stall.....\$1,312.86

Cost of Roundhouse, Coaling Station, Turntable, Etc.*—Mr. A. O. Cunningham gives data of which the following is a brief abstract. See *Engineering-Contracting* for full description of the plant with drawings.

In 1907, the Wabash R. R. built a new engine terminal plant at Decatur, Ill., where 100 engines are cared for daily.

The roundhouse has a wooden frame resting on concrete foundations. The walls are of wooden girts to which expanded metal is fastened on both sides. The expanded metal on the outer surface is plastered on both sides with a mixture of Portland cement, lime and sand, and cocoanut fiber. The expanded metal on the inner surface is, of course, only coated on one side with the same kind of plaster. This construction provides a wall with a hollow space of air between, so that dampness cannot penetrate to the inner surface. The air space forms a good insulator to keep the building warm in winter and cool in summer. The plaster applied to these walls consists of 1 bbl. of lime mixed with 15 bbis. of sand and 4 lbs. of cocoanut fiber, the whole being mixed thoroughly with water and allowed to stand for at least two weeks so as to give the lime time enough to slack thoroughly. One part of Portland cement is added to three parts of this mixture, with enough water added to make a plastic

**Engineering-Contracting*, Apr. 28, 1909.

mortar. This is applied to the expanded metal and allowed to harden. This is called a scratch coat. On this coat is plastered another layer of mortar, composed of 3 parts of sand to 1 part of cement. The plaster on the expanded metal on the outer surface of the house is $1\frac{1}{2}$ in. thick, and that on the inner surface about $\frac{3}{4}$ in. thick. This hollow wall extends completely around the outside of the house, and from the ground to a height of 5 ft. The exterior face of the wall is painted with a waterproofing compound. On this wall is placed a continuous line of windows, which extend to the underside of the eaves of the building, thus providing plenty of light, which is very essential in such buildings. The cost of a wall of this description is slightly less than brick, but a saving is made because brickwork requires foundations to support it, while this construction requires only those necessary to support the posts. Also lintels are required over openings in brickwork, and none are required in this kind of a wall. A further advantage in this construction is that a continuous line of windows may be used, while with brickwork this is not possible, on account of the pilasters. The windows are made so that the two lower sashes are hung together with copper chains over pulleys; thus when one is raised the other is lowered; consequently they are counterbalanced without going to the expense of providing box frames with counterweights.

The floor of the roundhouse is of concrete, built similarly to a sidewalk, and placed on cinders. It is laid out in squares of about 3 ft. to the side, so if any square gets broken, as it is liable to be on account of the heavy pieces handled in a house of this description, it can be repaired at small cost.

The foundations carrying the posts are of concrete and are entirely separate from the floor, so if any settle, the floor will not be disturbed.

On the roof sheathing is laid a built-up roof of 5-ply tar and crushed limestone. The crushed limestone not only adds weight to hold the built-up roof in place, but, being white in color, helps to protect the tar from the rays of the sun. The cost of this roof covering in place was about the same as that of a prepared roofing.

The turntable foundations are supported by piling and are of concrete. The center or pivot foundation is reinforced with rods just above the head of the piles. The circle rail is spiked to short ties laid without any fastenings on the circle wall. The pit is paved with concrete in a manner similar to that in the house and is drained by a 4-in. tile into the catch basin previously mentioned.

The turntable is of the deck type, 75 ft. long, with a live load capacity of 215 tons, and is turned by means of a tractor wheel running on the circle rail and operated by electricity. The steel work of the turntable was built by the American Bridge Co., and installed by employees of L. & Wabash R. R. Co.

There are 75 cu. yds. of cinders removed daily from the cinder pits by means of an electric gantry crane and clamshell bucket, this part of the plant being made by the Case Mfg. Co., of Columbus,

Track between turntable and engine house and labor laying (value new).....		\$ 84,545
Turntable pit and foundation.....	\$ 3,360	\$ 1,955
Turntable	2,430	
Circle rail and track on turntable (value new).....	685	
Machinery for operating turntable.....	1,075	7,550

Sand house and machinery (value new).....		2,000
50,000-gal. water tank and fixtures (value new)....		1,100
Three water cranes with water pipes and fixtures, etc. (value new).....		1,000
		<hr/> \$118,185

NOTE.—Items with the words "value new" written after them indicate that the material or structure had been formerly used with the old facilities. The amount given is the cost if new.

Cost of a Brick and Steel Building.*—Mr. A. E. Duckham is author of the following:

In the spring of 1907 the writer was called upon to design a building for a wire-glass plant in South Greensburg, Pa., for the Arbogast-Brock Glass Co.; the wire-glass to be made under a new process of Mr. John Arbogast, who is now superintendent of the plant which has been completed. The building, which is 60 x 170 ft., was started (breaking ground) on May 20 and was finished by the author on Aug. 1. This includes thelehr (furnace) foundations.

The foundations up to the level of the ground are of concrete, made of 1 part cement (Portland), 2 parts sand, and 7 parts gravel. They were carried down to clay, which on an average was 3 ft. below the surface of the ground, which was level. As the ground

**Engineering-Contracting*, Apr. 15, 1908.

was marsh-like, the trenches were dug and immediately filled up with concrete, mixed on the board and deposited by wheelbarrow from a plank runway into the bottom. No water was required in the mixing-board for the bottom layers of concrete, owing to the trenches being partly filled with surface water. After standing all night we would find the trenches filled with water in the morning; this we pumped out with an ordinary hand-pump and trench suction hose (about 3 in. in diameter). At times, it kept one man busy pumping all day, owing to the heavy rains to which we were subject, which kept the ground saturated.

Above the level of the ground the building is of brick. The roof-trusses are of steel, including the purlins. They rest on the pilasters of the wall, and are attached to them by anchor bolts. The latter were set loose in the walls; and, after the erection of the steel, were grouted with cement mortar. This was to facilitate the erection of the steel-work.

The roof was covered as follows: Nailing strips of 2 x 4 in. hemlock were bolted (every 3 ft.) to the steel purlins, and upon them was nailed 1½ in. matched yellow-pine sheathing; upon this was laid and fastened Carey's Magnesia Flexible Cement Roofing.

The building was well situated for receiving materials, as it was located 118 ft. from the railroad and 75 ft. from a street. The cement, sand, gravel and brick were obtained from local dealers within a mile of the place; the first three were hauled by wagon (with the exception of one carload of sand), and the last one was shipped in by car on a siding opposite the building, and slipped in by a chute, the railroad track being about 8 ft. above our ground.

The walls between the pilasters are only 9 in., but the pilasters project 3 in., thus making an 12-in. pillar or column under each truss to carry the load; the 9-in. wall between acting as a curtain wall. The brick wall was laid complete in cement mortar, no lime being used. The mortar was composed of 1 part of cement and 2½ parts of clean river sand. When the building was finished, the mortar was so hard that it was difficult to break it with a hammer. We had some trouble at first with the bricklayers to get them to use this mortar without the addition of lime, as it is not easy to spread. When set up, however, it lasts for all time.

The cement, an American Portland, gave us perfect satisfaction. This was used throughout—in foundations, brick walls and lehr (furnace) foundations. Partly in the lehr foundation we used furnace slag from the steel works in place of gravel, being unable to obtain the latter in time. It was very satisfactory, but required much more water in mixing, which had to be carried from a creek about 100 ft. distant.

The steel half trusses were skidded off the cars onto the ground, brought into the building after the erection of the walls through one of the large doorways on a "buggy," riveted together to form complete trusses, and then raised into position by a gin-pole, block and tackle, and crab (the latter being operated by six men). There were ten steel erectors, and it took them about ten days to

erect the steel-work, including trusses, purlins, lateral bracing (in three bays) and "sag rods." A day or so was lost, however, waiting for tools and material.

On the original plans we figured on regular ventilators or lanterns with side louvres of sheet steel extending the whole length of the ridge of the roof for ventilation; but, at the suggestion of the owners, to save cost, these were omitted, and four ordinary circular ventilators were used along the ridge. As there were many large windows along the sides of the building, as well as the ends, these were considered enough for the purpose. The windows had boxes for pulleys and weights. There were two sash to each window. The bottom sash weighed 39 lbs. including the glass; this was weighed to determine the size of counter-weights.

The 123 squares of roof-covering took one week to lay, nail, cement, and paint. There were five men for three days and two men for six days. Two men (experts) came up on the job, and three ordinary local mechanics were hired. The extra men cost \$20.

In unloading the brick from the cars on the railroad track, in one case it took five hours to unload one box car of 12,000 brick with four men (two inside and two outside), with chute; and in another it took 2½ hours for five men to unload the same car.

The building was not only designed by the author as engineer and architect, but he also had the contract to erect the building complete on the "cost-plus-a-fixed-sum" plan. By this method, the owners saved at least \$2,000 figuring on the lowest bids, or about 15 per cent of the net cost (not taking into account the architects and contractors' commission). The building was originally intended to be built at Carnegie (about five miles from Pittsburg), but was finally built at Greensburg (over 30 miles from Pittsburg), where everything, owing to the increased distance from a large city and a river (for sand and gravel), cost more. The bids were figured on the Carnegie location, consequently the percentage showing the amount saved in cost should be increased.

The average lump bid of the contractors was about \$11,500, but this was for the Carnegie location. To show the increased cost of the same building at Greensburg, we got a bid on the brickwork from the same man of \$1,955 at Carnegie and \$2,400 at Greensburg, or an increase of over 22 per cent. Again cement cost \$1.75 per barrel at Carnegie and \$1.85 at Greensburg, while sand cost 7½ cts. a bushel at Carnegie and 8 cts. at Greensburg.

The detailed cost of the building as built was as follows:

Steel-work	\$2,730.00
Lumber, doors and windows, sheathing, etc. . .	1,252.64
Roof covering (cement roofing felt)	412.50
Cement, sand and gravel	936.04
Brick	722.46
Labor (including common labor, bricklayers and carpenters)	2,175.52
Bolts to fasten nailing strips to purlins	22.22
Hardware	79.54
Ventilators (circular)	12.00
Total	\$8,404.82

The cost of the building per cubic foot of space from the ground level to the roof was 3¼ cents. The cost per square foot of floor space was 82.4 cts. The above does not include the architect's fee of 5 per cent or the contractor's fee (of approximately 8 per cent); this would bring the cost per cubic foot up to 3.6 cts., and the cost per square foot up to 93.1 cts.

The building was filled in to a depth of 4 ft. with dry earth and burnt sand (from a foundry nearby). It was originally intended to lay a cement floor upon this, or a brick floor (preferably the latter, as being easier to take up for the additional lehrs); but this was abandoned for the present, until the filling would become well tamped down by walking and by rolling trucks over it.

The lehr walls (foundation) were built by the writer under a separate contract with the furnace contractors. This work he did for \$6.50 a cubic yard for the concrete walls (3 ft. under ground and 4 ft. above ground) and 50 cts. a yard extra for excavating the trenches. At this figure, he made 18 per cent profit. There were some advantages and some disadvantages. Under the head of advantages were the facts that his foreman, who was overlooking the main building, also took charge of this work; then for casing or forms for the concrete we used sheathing and lumber afterwards used on the building; under the head of disadvantages were the handicaps of having to carry water for the concrete and that we were held up by the steel erectors, who got in our way. The carpenter work in building the forms for the concrete lehr foundations amounted to 10 per cent of the total labor bill. The total labor bill amounted to 28 per cent of the total cost, and the materials (cement, gravel, slag, and sand) consequently run up to 72 per cent of the total cost. Runways were built of inclined planks, and the concrete was deposited by wheelbarrows directly into the forms and then tamped. The writer believes in rather a wet mix of concrete, tamped enough to bring the water to the surface, and make it liver like (quaking).

Inclined runways and scaffolding of 2-in. plank and doubled 2 x 4-in. studs as posts were also used in the main building to supply the bricklayers with brick and mortar. Up these, common laborers wheeled the material in barrows; thus doing away with the slow and more expensive hod-carriers and ladders. The material used in the construction of the runways and scaffolds was afterward used in the room, so there was but little waste of lumber.

The plans, with the exception of the details, were made on ¼-in. scale, instead of the usual ⅛-in. scale. This smaller scale made it more convenient in the field, and not so cumbersome, especially when there was a strong wind. The writer believes that as small a scale as possible should be used, and all details should be made on a separate sheet on say 1-in. or 1½-in. scale. Figures in all cases should be given instead of depending on the scale. This would remove all doubt and controversy. In fact we should follow the procedure of the bridge drafting room.

In designing the building, no attempt was made at ornamentation, as the owners wanted the building to cost as little as possible; but the writer saw to it that everything was strong and efficient.

The brickwork was laid in English Bond, the strongest kind; and the writer was surprised to find how few of the so-called practical bricklayers knew what it was or how to lay it. Most of them thought that it was Flemish bond—or alternate headers and stretchers—instead of alternate layers of headers and stretchers, which is the English Bond.

Cost of Reinforced Concrete Buildings.—The following is a very brief abstract of a five-page article by Mr. Leonard C. Wason, President Aberthaw Construction Co., in *Engineering-Contracting*, Jan. 13, 1909. [The labor unit costs are rather high. The work was done in New England.]

It is well known that the cost of materials and labor in different parts of the country vary somewhat. Having the unit items all sub-divided into their elementary parts, it is an easy matter after determining the cost of materials in any locality to make the exact corrections to the results obtained on a previous job. Similarly, when a difference in the rate per hour for wages is known, if the same efficiency is obtained from the men it is very easy to make a correction, or if the efficiency varies, judgment must be applied to determine the correct rate to use. It has been the writer's experience that although the rate of wages and cost of materials vary somewhat in different parts of the country, the variations frequently offset one another so nearly that the sum total of the unit cost obtained in one place may be used in another, very seldom needing correction. For instance, within one month, after careful investigation, a bid was made up on a structure at San Juan, Porto Rico, using the same unit costs as for a building in Boston. In the report that is given, the costs relate to strictly first class material and workmanship in every case, as it has been the endeavor of the writer to establish and maintain one standard for all work. In general I would say that the standard mixture for all floors has been either 1-3-6, or 1-2-4 if the floor is subjected to extremely heavy loads and service. Walls are mixed 1-3-6 and columns usually 1-2-4; in some cases where they are very heavily loaded a richer mixture is used. As these mixtures are common to nearly all construction the costs here given may be applied with little danger of error from neglecting the mixture on any work. Of course it can readily be understood that in the large number of jobs which have entered into the averages given, there being as many as 18 in the case of beam floors, different methods of conducting the work have been used and many different foremen. Therefore, while the general average is doubtless safe for any work of an average character, some latitude may be allowed the judgment in determining whether any specific case is likely to be difficult, easy or average. The writer has found quite a difference, for instance, in cost of identical work handled by different foremen, due to the personal equation of their painstaking supervision and ability.

Cost of Columns.—The following costs are the average of 9 buildings:

	Per cu. ft. of concrete.
Cement	\$0.025
Sand and stone.....	0.049
Labor on concrete.....	0.096
General labor	0.027
Team and miscellaneous.....	0.021
Plant	0.023

Total, exclusive of steel and of forms.....\$0.301

The cost of forms per square foot of concrete surface encased was as follows:

	Per sq. ft.
Lumber at \$22 per M.....	\$0.036
Nails and wire.....	0.001
Carpenter labor	0.083

Total

This includes all necessary posts and staging, also wheelbarrow runs for placing the concrete.

Cost of Beam Floors.—The average cost for 13 buildings was:

	Per cu. ft. of concrete.
Cement	\$0.106
Sand and stone.....	0.063
Labor on concrete.....	0.111
General labor	0.020
Team and miscellaneous.....	0.025
Plant	0.024

Total, exclusive of steel and of forms.....\$0.354

The cost of forms per square foot of concrete surface covered was:

	Per sq. ft.
Lumber at \$22 per M.....	\$0.045
Nails and wire	0.002
Carpenter labor	0.070

Total

Cost of Flat Slab Floors.—The average cost of 3 buildings was:

	Per cu. ft. of concrete.
Cement	\$0.096
Sand and cement.....	0.070
Labor on concrete.....	0.097
General labor.....	0.009
Team and miscellaneous.....	0.019
Plant	0.024

Total, exclusive of forms.....\$0.315

The cost of forms was:

	Per sq. ft.
Lumber at \$22 per M.....	\$0.033
Nails and wire.....	0.002
Carpenter labor.....	0.071
Total	\$0.111

Cost of Concrete Slabs Between Steel Beams.—The average cost for 13 buildings was:

	Per cu. ft. concrete.
Cement	\$0.128
Sand and stone.....	0.068
Labor on concrete.....	0.102
General labor.....	0.019
Team and miscellaneous.....	0.024
Plant	0.017
Total, exclusive of steel and of forms.....	\$0.359

The cost of forms was:

	Per sq. ft.
Lumber at \$22 per M.....	\$0.032
Nails and wire.....	0.002
Carpenter labor.....	0.061
Total	\$0.095

Cost of Walls.—The average cost of concrete walls (above grade) for 17 buildings was:

	Per cu. ft. concrete.
Cement	\$0.073
Sand and stone.....	0.076
Labor on concrete.....	0.090
General labor.....	0.016
Team and miscellaneous.....	0.025
Plant	0.019
Total, exclusive of steel and of forms.....	\$0.301

The cost of forms was:

	Per sq. ft.
Lumber at \$22 per M.....	\$0.036
Nails and wire.....	0.002
Carpenter labor.....	0.085
Total	\$0.123

Cost of Foundation Walls.—The average cost for 14 buildings was:

	Per cu. ft. concrete.
Cement	\$0.080
Sand and stone.....	0.062
Labor on concrete.....	0.076
General labor.....	0.015
Team and miscellaneous.....	0.019
Plant	0.017
Total, exclusive of forms.....	\$0.269

The cost of forms was:

	Per sq. ft.
Lumber at \$22 per M.....	\$0.033
Nails and wire.....	0.002
Carpenter labor.....	0.063
Total	\$0.102

Cost of Footing and Mass Foundations.—The average cost for 10 buildings was:

	Per cu. ft. concrete.
Cement	\$0.071
Sand and stone.....	0.077
Labor on concrete.....	0.045
General labor.....	0.007
Team and miscellaneous.....	0.007
Plant	0.021
Total, exclusive of forms.....	\$0.229

The cost of forms was:

	Per sq. ft.
Lumber at \$22 per M.....	\$0.034
Nails	0.002
Carpenter labor.....	0.057
Total	\$0.093

Cost of Labor on Reinforcing Steel.—Table XI omits entirely the first cost of the material. After it is received at the site of the work in the shape sold by the manufacturer, these prices cover the cost of fabricating into units for columns or beams, bending the stirrups, placing and all incidentals whatsoever prior to the actual embedding in concrete. In the case of the highest cost, a coal pocket, there was very limited storage space, 1½-in. bars had to be bent diagonally so as to pass over the top of the support at columns, and there were numerous stirrups, all of which had to be made by hand. The job was too small to justify any mechanical arrangement for bending or for handling material. The next highest, office building, Portland, Me., there was a sufficient amount to require proper machinery. The hoops for columns were all welded. The vertical bars were all wired inside of these hoops. There was a mushroom head of bent and circular bars wired together at the top and great numbers of long bars of small section spread in all directions over the floor. The lowest price, filter at Lawrence, was made entirely of straight bars placed loose, the only expense being cutting them in a hand shear to length and placing them.

TABLE XI.—STEEL.

Location.	Weight. Tons.	Cost of handling.	Cost per ton.
Office building, Portland, Me.....	324 1/2	\$5,115.32	\$15.76
Fire station, Weston, Mass.....	8 1/2	40.86	4.74
Mill, Chelsea, Mass.....	65 1/2	548.81	8.41
Coal bins, Dalton, Mass.....	8 1/2	61.75	7.26
Dam, Auburn, Me.....	55	506.76	9.18
Filter, Warren, R. I.....	19	102.59	5.40
Tank, Lincoln, Me.....	8 1/2	69.38	8.16
Tar well, Springfield.....	15 1/2	59.21	3.82
Monument, Provincetown.....	24 1/2	136.84	5.58
Mill, Greenfield.....	92 1/2	1,232.01	10.20
Machine shop, Milton, Mass.....	20 1/2	177.16	8.75
Coal pocket, Lawrence, Mass.....	28	461.16	16.47
Mill, Southbridge.....	53 1/2	142.78	2.67
Mill, S. Windham, Me.....	293	3,079.60	10.51
Mill, Attleboro, Mass.....	49 1/2	286.02	5.78
Garage, Newton, Mass.....	26	86.55	4.33
Mill, Southbridge, Mass.....	30	100.03	3.34
Coal pocket, Hartford, Conn.....	195	2,316.60	11.88
Filter, Lawrence, Mass.....	44 1/2	112.84	2.54
Warehouse, Portland, Me.....	62	462.99	7.47
Standpipe, Attleboro, Mass.....	199 1/2	1,547.00	7.75
Highest			16.47
Lowest			2.54
Average of 21.....			8.52

Cost of Reinforced Concrete Building Construction.*—Mr. T. Herbert Files is author of the following:

The costs here given are those of labor only, as labor costs are usually the unknown ones in estimating, the material costs being easily obtained from the schedule of quantities and the market prices.

These costs are taken from different work which the writer has been on and are known to be correct for that kind of work. They are not obtained from rough figures after the work was finished, but from carefully kept cost records. All of the costs are from jobs consisting of a number of buildings.

The cost analysis was kept in the following manner. Each job had a cost keeper whose only duties were those of keeping the average weekly cost of the different work of construction. The distribution of the time was taken either from foreman's reports or from time cards. Most of the costs given in this article are obtained by means of time cards.

Time cards are rather difficult to get from the ordinary labor employed on construction work, but this difficulty was overcome by having the foreman of the labor gangs make out cards for each man in his crew. The carpenters and better class of laborers made out their own cards. Each man had to pass in a time card as he checked out at the timekeeper's window at night. In this way the record of each man's time and how it was spent, was passed into the office each night, and no special men were lost, as usually happens when the distribution is taken from foremen's cards.

* *Engineering-Contracting*, Apr. 7, 1909.

The cost keeper would go over these cards the next day and enter the totals of the labor of each class of work on the cost keeping sheets. The record was divided into different accounts, one for each division of the work, such as excavation, concreting, forms, floor finish, steel, etc. All time was charged against its proper account in such a way as to show the date, kind of work, total time, and wage rate, as shown by the accompanying form.

The total number of hours in the analysis was checked up each day with the total number of hours on the timekeeper's sheets. At the end of each week the total cost of each kind of work for the week and the unit cost were figured up and a summary made of the totals of the different accounts. This total was then compared with the pay-roll. If everything has been carried through correctly, the two totals should check within a few dollars. They will not check exactly, as average wage rates are used in the cost keeping.

Wages.—As cost figures do not mean much unless the rates of wages are known, the average rates paid will be given. They are as follows:

Common labor, as used in excavating, unloading materials, and unskilled work, 17½ cts. per hour; foreman, 30 cts.; concrete labor, 18 cts. per hour; foreman, 40 cts.; steel labor, 25 cts. per hour; foreman, 30 cts.; form labor, used for stripping and rough carpenter work, 30 cts.; carpenters 41 cts. per hour, and foreman, 50 cts.

Cost of Unloading Materials.—Cement is usually unloaded by laborers carrying the bags on their shoulders from the car, or by wheeling in wheelbarrows. If a car can be unloaded direct from the car into the storage shed, with very little carrying, six men can unload 600 bags equivalent to 150 bbls., in 3 hours, at a unit cost of 2 cts. per bbl. If unloaded by wheelbarrows with a distance of 100 ft., it will cost 4 cts. per bbl., but may run up to 5 cts. or 6 cts. if the men are not handled in the proper manner.

Sand and gravel will cost on an average of 3 cts. per cu. yd. for unloading, laborers shoveling it from the car to the storage pile nearby. The cost varies from 6 to 10 cts., depending upon conditions.

Reinforcing steel bars can be unloaded at a cost varying from 25 cts. to \$3.00 per ton, depending upon the carrying distance. Here are some actual costs:

Unloading ¾ in. x 20 ft. twisted steel, from box cars and piling it on ground beside car 22 cts. per ton.

Unloading from gondola cars, carrying 300 ft. and piling on racks in steel shed, \$3.00 per ton.

The unloading of lumber differs considerably in cost, same depending upon the distance carried and the size of the sticks. It was found, however, from our records that it cost from 70 cts. to \$1.00 per 1,000 ft. B. M. to unload, haul 300 ft. and pile, form sheathing.

Form Work.—The cost of form work is the most difficult cost to get in reinforced concrete construction. This is especially so in regard to the making of forms, as the work on construction jobs is usually done in such a manner that it is hard to distribute the costs

properly and have the correct amount of work done, reported. The cost work here referred to was not started in the best way to give good costs of the making of forms and for that reason the costs of making forms will not be as complete as might be. The unit costs were figured on the number of square feet of form surface in contact with the concrete.

The following are some of the labor costs of forms made in a field carpenter shop, which consisted of two saw machines, a planing and a boring machine, with a shop foreman in charge.

	Per sq. ft. of surface.
Columns	cts.
Girders and beams.....	5 cts.
Floor panels.....	3 cts.
Wall panels.....	3 cts.

The cost of setting forms for the floors, which included time spent in the moving of the forms from one floor to another, erecting and setting the forms of columns, beams, and floor panels and the falsework supporting them, was figured per sq. ft. of floor surface. The costs of different floor set-ups varied, because the men at first were unskilled and not well organized. From 1,300 to 1,800 sq. ft. of floor were set up in a day. These costs ranged from 13 cts. per sq. ft. for the first set-up to 4.7 cts. for the roof set-up, making an average of 8.4 cts. per sq. ft.

The stripping of the floor forms cost from 2.5 cts. to 1.5 cts. per sq. ft., or an average of 1.9 cts. per sq. ft. of floor. This makes the cost of setting up and stripping of forms for floors average 10.3 cts. per sq. ft. of floor.

The curtain walls, between columns, were put in place after the floors and cost from 6 to 10 cts. per sq. ft. of form surface for setting up, or an average of 8 cts. The cost of stripping these was $\frac{1}{2}$ ct. per sq. ft. Partition walls and outside plain walls cost from 4 to 8 cts. per sq. ft. of form surface or an average of 5 cts. for setting and $\frac{1}{2}$ ct. per sq. ft. for stripping.

Reinforcing Steel.—The steel used for reinforcing was twisted rods. The column cages, beam and girder reinforcements were made up into units in the steel yard. From there they were carried and hoisted to the different floors, as they were made ready for concreting, and were put in place by the steel gang before concreting. The floor steel was placed as the floor was concreted.

The cost of the steel work is divided as follows:

	Per ton.
Unloading	\$ 2.00
Making up steel.....	5.50
Carrying	1.75
Placing	1.00
Total	\$10.25

Concreting.—The labor costs in concreting vary a great deal with the plant and method of conveying. On this work, the concrete was machine mixed, the materials being run into storage hoppers

over the mixer, by a self dumping car, on an inclined track, from the material pile, where it was loaded by hand. The concrete after being mixed, was raised to the proper floor by a hoist, which dumped automatically into a hopper. From this hopper the concrete was wheeled to the desired location by means of concrete carts. The greatest wheeling distance was 350 ft. and the least 50 ft., making the average distance 200 ft. The costs of concreting columns and floors ranged from 2.8 cts. to 4.3 cts. per cu. ft., or an average cost of 3.5 cts. per cu. ft.

In concreting footings, the material was moved to the mixer by means of wheelbarrows instead of self dumping cars, and wheeled to the desired location over plank runs. Under these conditions the cost of concreting was 5 cts., with the carrying distance the same as for the floors.

Cost of Reinforced Concrete Factory.*—Mr. D. L. C. Raymond gives the following relative to a building erected in 1907 at Walkerville, Ontario. It is a two story factory, 100 x 100 ft., with 18 ft. clearance on the first floor and 12 ft. on the second. It is skeleton type of construction, 16 x 16 ft. floor panels, and 6-in. curtain walls. Steel rods were used for reinforcement with wire mesh in the slabs. A 1:2:4 mixture was used, the mortar finish on the floors being 1:2.

The columns and beam forms were 2-in. dressed pine, supported by 4 x 4 stuff. The floor forms were 1 in. laid on 2 x 4 pieces spaced 18 ins.

The men were all green at the work. There were 847 cu. yds. of concrete, the cost of which was as follows:

Materials:	Total.	Per cu. yd.
Cement at \$2.05 per bbl.....	\$ 2,314	\$ 3.01
Sand and gravel at \$1.25 per cu. yd.....	1,054	1.25
Reinforcement at \$55 per ton.....	2,314	2.73
Lumber for forms at \$27 per M.....	4,944	5.84
Nails	107	0.13
Total materials.....	\$11,732	\$12.86
Labor:		
Building runs, mixing and hoisting concrete.\$	\$ 773	\$ 1.03
Placing and tamping concrete.....	562	0.66
Placing reinforcement.....	221	0.26
Stripping and cleaning forms, etc.....	380	0.45
Carpenters building and setting forms.....	2,010	2.38
Superintendence	714	0.84
Tools and depreciation of plant.....	339	0.40
Total labor.....	\$ 5,097	\$ 6.02
Grand total.....	16,830	19.88

It will be noted that no salvage is allowed for the lumber, and that 216 ft. B. M. were used per cu. yd. of concrete. The carpenter work on the lumber cost \$11 per M. The cost of stripping lumber and cleaning up amounted to a little more than \$2 per M.

There were 100 lbs. of reinforcement per cu. yd., and the labor of placing it was only a trifle more than $\frac{1}{4}$ ct. per lb.

**Engineering-Contracting*, Apr. 29, 1908.

This building contained about 320,000 cu. ft. of space. Hence the cost of the concrete alone was $5\frac{1}{4}$ cts. per cu. ft., which is a low cost. The cost per square foot of floor area (2 stories) was 24 cts., not including windows, etc.

Cost of a House of Separately Molded Concrete Members.*—The construction of a kiln house of separately molded reinforced concrete columns, girders and slabs for the Edison Portland Cement Works at New Village, N. J., was described in our issue of Oct. 2, 1907. (See also "Concrete Construction," by Gillette and Hill.) This article gave for the first time costs of molding and erecting separately molded concrete structural members for building work. Since it was published the same company has built a cement storage house for which the columns, girders and roof slabs were separately molded and erected. In a paper by Mr. W. H. Mason, superintendent Edison Portland Cement Works, some of the costs of this later work were given. We give these costs in different form and more fully analyzed in the following paragraphs.

The storage house is 144 x 260 ft., in plan with a clear height of 30 ft. The exterior walls are of retaining wall section, they having to take the thrust of the stored cement, and they were built in place. Between walls are five longitudinal rows of columns; the rows are spaced 24 ft. apart and the columns in each row are 12 ft. apart. Transverse roof girders 12 ft. apart cap the columns and carry a roof of 8 x 12 ft. x 4-in. slabs. For column footings 6 x 6 x 5-ft. plain concrete cubes with 20-in. square sockets molded in their tops were used.

Materials and Labor.—The concrete used was a 1:4 mixture, using crushed run stone, all of which would pass a $\frac{3}{4}$ -in. screen. The Edison company furnished both cement and stone, charging up the cement at \$1 per barrel and the stone at 60 cts. per cu. yd. The lumber, of which 7,000 ft. B. M., were used, cost \$27 per thousand. The reinforcing steel, of which 101,400 lbs. were used, cost delivered 2.03 cts. per pound. A force of 23 men was employed; eleven of them were classed as carpenters at an average wage of 24 cts. per hour and 12 as laborers at an average wage of 15 cts. per hour.

Casting Floor and Plant.—The casting floor on which the columns, girders and slabs were molded, was located some half a mile from the building. A $\frac{1}{2}$ cu. yd. Ransome mixer was set up under the mill conveyor which carries crushed cement rock for cement making to the stock house and from this conveyor the stone was chuted directly into the mixer stock bins as wanted. The mixer discharged directly into 3 cu. yd. cars which ran out on a track between casting floors on each side. The casting floors consisted of trowel finished concrete slabs 4 or 5 ins. thick laid on a 4-in. sub-base of compacted cinders. These casting floors cost, Mr. Mason states, 4 cts. per square foot. So far as possible, members were cast side by side and in tiers so as to reduce floor space and form work. The concrete cars discharged by spout directly into the molds, the mixture being made wet enough to flow easily.

**Engineering-Contracting*, Mar. 18, 1908.

Molding Columns.—There were 141 columns, having 18 x 18-in. shafts 32 ft. long with two triangular brackets at the top for girder seats, and each column contained very closely 2.8 cu. yds. of concrete and 275 lbs. of reinforcement or closely 98 lbs. of steel per cubic yard of concrete. These quantities are computed from drawings. The construction of the forms for molding the columns is shown by Fig. 7. Each complete form contained about 535 ft. B. M. of lumber and seven were used for molding 141 columns and were still in good condition after the work. The seven molds contained about 3,745 ft. B. M. of lumber and molded $141 \times 2.8 = 395$

Fig. 7.

cu. yds. of concrete, so that the amount of form lumber used per cubic yard of concrete molded was about 9.7 ft. B. M. The costs of molding per column and per cubic yard were as follows:

Item	Per col.	Per cu. yd.
Steel reinforcement.....	\$ 7.57	\$2.70
Concrete materials.....	5.48	1.96
Labor, carpenters.....	4.27	1.52
Labor, concrete and steel.....	1.95	0.70
Total cost.....	\$19.27	\$6.88

Molding Girders.—There were 187 girders, each 12 x 26 in. x 24 ft. and each containing 1.9 cu. yds. of concrete and about 320 lbs. of steel or about 168 lbs. per cubic yard of concrete. A complete girder form is shown by Fig. 8. A complete form contained approximately 370 ft. B. M. of lumber and five forms, or 1,850 ft. B. M., were used for molding 187 girders, or about 5.2 ft. B. M. per cu. yd. of concrete in girders. It should be noted that many of the girders were molded between other girders without using any

Each slab covered $8 \times 12 = 72$ sq. ft. of roof, so that the cost of molding was 6.06 cts. per sq. ft. or \$6.06 per 100 sq. ft.

In casting columns, girders and slabs side by side and in tiers in contact the fresh concrete was prevented from adhering to the member already molded by coating the contact surface of the molded member with two coats of ordinary whitewash. This method proved far superior to using paper, as had been done in previous work. The paper stuck to the concrete so fast that it was difficult to remove it. It should be noted also that in the preceding cost figures the cost of form lumber is apparently included in "carpenter labor." There was 7,000 ft. B. M. of form lumber at \$27 per M. ft. required for molding 1,048 members, or about 1,384 cu. yds. of concrete. The cost of form lumber per cubic yard of concrete was, therefore, $\$189 \div 1,384 = 13.65$ cts.

The labor cost of erecting the molded concrete members with a Browning locomotive crane was as follows:

	Per cu. yd.
Columns	\$2.83
Girders	1.57
Roof slabs.....	1.75

The details of this cost of erection and the methods are given in Gillette and Hill's "Concrete Construction."

Comparative Cost of Constructing Two Identical Reinforced Concrete Buildings—One of Separately Molded Members and One of Members Molded in Place.*—Mr. Mason D. Pratt is author of the following:

In 1904 the Central Pennsylvania Traction Co. of Harrisburg, Pa., built a car barn and a repair shop of reinforced concrete, probably the first buildings in this country built entirely of this material for this purpose. The buildings are one story in height and were constructed in the usual manner by erecting wooden forms and casting all concrete work in place. The same company has just completed a second barn adjacent to the one above described of the same dimensions as the first barn, viz.: 75 ft. wide by 340 ft. long. The last barn is also of reinforced concrete, but owing to conditions which seemed favorable for the purpose, an entirely different mode of construction was followed. All of the members for that portion of the building above the foundation and floors, including columns, beams, wall and roof slabs, were separately molded on the ground and afterwards erected by means of a travelling stiff-leg derrick. This method of construction proved economical and owing to the close similarity of the two buildings in size and general design it is possible to make an accurate comparison of the costs. In describing the two buildings, Barn A refers to the original building and Barn B the last one erected.

Barn A was built on ground which was from 2 to 10 ft. below the floor level. The column footings were placed on solid ground 6 to 12 ins. below the sod and carried up within 1 ft. of floor level, the ground being filled in after the building was under roof. In general

**Engineering-Contracting*, Jan. 19, 1910.

plan the building had three rows of non-reinforced hexagonal columns spaced 15 ft. centers longitudinally and 37 ft. centers transversely. The roof consisted of transverse beams, resting on the columns, longitudinal purlins and a 3-in. slab cast in place, the columns being connected longitudinally with beams 6 ins. thick and 2 ft. deep. After the forms were removed from this skeleton the three longitudinal walls were filled in place. Provision was made for future extension laterally by casting brackets in the columns to support roof girders for an adjacent bay. The barn also had a wing 16 ft. wide and 99 ft. long, containing barn foreman's office, lockers and lavatory for the use of motormen, conductors and barn men.

Concrete for this building was mixed in a rotary batch mixer, into which the aggregate was dumped directly from wheelbarrows, and the concrete distributed from the mixer to the job in wheelbarrows by means of runs and an elevator operated by a power hoist.

Barn B was built entirely independent from Barn A, the first wall being placed 37 ft. beyond the wall of Barn A, thus permitting the increase of the plant by one addition bay in the future by simply adding a roof between the two buildings. Column spacing was made the same as Barn A, but the columns were square. In order to get roof slabs of a size which could be conveniently handled, the roof beams were spaced 10 ft. centers and alternated in the two bays. Thus on the outer walls a roof beam came at every other column, while on the center wall each column carried a beam and a longitudinal beam between columns supported the ends of two roof beams. The roof proper consisted of slabs, $3\frac{1}{4}$ ins. thick, 10 ft. long and 6 ft. and 7 ft. wide, which were laid directly on the roof beams. Two slabs at the center of every alternate 10 ft. bay were omitted to allow placing skylights. The walls were 6 ins. thick, as in the case of Barn A, but were made up of slabs of various sizes. These slabs were all tongued and grooved, as were also the columns. Three-eighths of an inch was allowed for all joints, the horizontal joints being mortared as the work was laid up and the vertical joints filled and pointed after everything was in place. A small percentage of reinforcement was placed in all slabs as an insurance against breakage in handling.

The concrete for this building was mixed in the same mixer used on Barn A, located at a central point, the materials being moved in wheelbarrows as before.

Barn A had about 290 ft. of open pits under each track, 60 ft. of the front end of each bay being paved with granolithic floor and used as space for washing cars. Barn B had the same arrangement in one bay, the other bay, which was intended for storage purposes only, had granolithic floor from end to end. The ground on which Barn B was built had been filled in with various materials, mostly clader from a nearby steel plant, and excavations had to be made for all foundations. In the figures given below, all labor for excavation in both buildings is omitted. In Barn B each column had a separate footing as in Barn A, which, however, was carried to a point 15 ins. above floor level, and provided with a pocket to

receive the column. A layer of sand was put in each pocket to give the column good bearing and to adjust height. A beam 12 in. wide and 2 ft. deep connected these footings, being cast at the same time with the footings.

The tracks were laid in the storage bay and the granolithic floor cast in place at the time of starting excavations for the foundations, and as soon as the floor was in place the casting of beams, columns and slabs began. The beams and columns were nested by casting the alternate pieces a suitable distance apart, and after removing the forms these became the forms for the intermediate pieces. The slabs were cast in piles, the ends being offset to enable rapid handling. The pieces were separated by means of 40-lb. waxed manila paper. No difficulty whatever was experienced during the erection in separating. In some instances soap was used, but the results were not as satisfactory and the cost was higher than with the paper. The surface of the pieces formed by paper separation showed a close, smooth, dull surface, except for the wrinkles formed by the paper, which was not heavy enough to prevent wrinkling. The paper was also responsible for other defects in the surface finish, owing to the mortar running in between joints where the paper overlapped and forming thin silvers. The paper was easily removed with water from a 1-in. hose, with nozzle $\frac{1}{4}$ in. The top surfaces of all pieces, of course, were troweled. This gave a rather variegated wall surface to the structure, but a coat of cement wash using a thin mixture of about equal parts of cement and limestone dust applied with whitewash brushes produced a fairly uniform appearance. This method of construction involved the use of slightly more reinforcing steel and a larger yardage of concrete, but the saving in forms, lumber and carpenter work was more than sufficient to pay for this difference and the additional cost of derrick and erection labor.

The number of loose pieces required was 1,466. These were completely erected in 33 working days, with a loss of only three slabs from breakage.

The derrick used was a standard stiff-leg with 60-ft. boom and 38-ft. mast, mounted on a truck so that it could be moved around the work. Power was furnished by a regular street railway motor through a gear bolted to the flywheel on the driving shaft of a two-drum hoist, the motor being equipped with standard street railway controller and suitable resistance coils. A traction company motorman operated the hoist and a rigger crew placed the material. The heaviest pieces handled were the roof beams, which weighed $7\frac{1}{2}$ to 8 tons. A number of special devices were used to handle the various pieces. For the heavy beams a loop was formed at the quarter points by bending a reinforcing rod, bringing it flush with the top of the beam and scooping out a portion of the concrete while green, and a special hook used to engage this loop. These hooks entered the slotted ends of a steel spreader. The rig was thus adjustable for variable spacing of the loops and for balancing. The slabs were handled by means of slings, holes being formed in

the slabs with a short section of $\frac{1}{2}$ -in. gas pipe for receiving bolts. In setting up the side walls, these holes were used to fasten 2 x 4-in. sticks on each side of the three wall slabs of each bay, thus keeping them in line, and by means of props, in a vertical position until erection had proceeded far enough to remove them.

Table XII gives complete detailed cost of all the concrete work in Barn B.

Table XIII is a comparison of the average costs of all the concrete work on Barns A and B, the figures covering all charges except general supervision. The concrete aggregate is put at same figure in each to eliminate any difference in unit cost of these materials. The mix was practically the same in each, the largest percentage being 1:2:4. Unit costs for labor were the same in both cases, viz.: ordinary labor, \$1.25 per day, and carpenters, \$2.50 per day.

It will be noted more steel was required in B, but very much less form material and labor. The roof of Barn B required more concrete, as all beams and slabs had to be treated as simple members, whereas in Barn A full advantage was taken of the T sections. Making full allowance for these differences the actual cost of the concrete structure of Barn A over Barn B was 15 per cent. Both buildings were constructed by day labor from plans made by the writer and under his direct supervision.

Cost of Metal Forms For Concrete Building Work.*—In *Engineering-Contracting* for Sept. 16, 1903, we describe a system of

**Engineering-Contracting*, Feb. 10, 1909.

metal column and floor forms for concrete building work that had been worked out by Mr. W. L. Caldwell of Canton, Ohio. In a paper read at the recent annual convention of the National Cement Users' Association Mr. Caldwell gives some estimates of the cost of these forms which are of interest. These costs are based on a 16-in. square column, with a girder beam 8 ins. wide and 18 ins. deep below floor slab, and with the lateral beams 6 ins. wide and 12 ins. deep, and floor slab 4 ins. thick.

For a structure of this character, Mr. Caldwell recommends the use of 10-gage material for the angles at the four corners of the columns, 14-gage for the lining of the columns, 14-gage for the girder boxes, 16-gage for the lateral beam boxes and 18-gage material for the channel boards forming the intercolumn area for carrying the floor slab, with all necessary reinforcing angles, bolts, etc., to set up the work complete ready for receiving the concrete.

The costs are as follows:

Column centering per lineal foot.....	\$1.75
Girder centering per lineal foot.....	1.00
Lateral beam centering per lineal foot.....	0.50
Floor area per square foot.....	0.12½
Adjustable girder and beam box posts per lin. ft..	0.05

Throwing the cost of all of these items against the floor area, the average is about 45 cts. per sq. ft.

This price is arrived at by taking a building 50 x 100 ft. with 28 columns and 18 bays or intermediate column spaces, each space or bay containing 227 sq. ft., in round numbers, each bay divided by two intermediate cross beams, or three spans to each bay. These figures will vary somewhat with the different types of buildings but will give, it is stated, a fair idea of the average cost.

Under ordinary conditions these centers can be erected at a cost of approximately 1½ cts. per sq. ft. for labor.

Cost of Concrete Building Blocks.—Mr. L. L. Bingham gives the following data. Letters were sent (1905) to more than a hundred makers of concrete blocks in Iowa. Most of the replies gave data relating to blocks for walls 10 ins. thick. The average cost per square foot of blocks for a 10-in. wall was:

	CU
Sand	2.0
Cement, at \$1.60 per bbl.....	4.5
Labor, at \$1.88 per day.....	3.8
Total, per sq. ft.....	10.3

The labor of making the blocks includes mixing, molding, sprinkling, piling and re-piling during or after curing. The average output per man was 48½ sq. ft. (1½ cu. yds.) per day.

The 10½ cts. however, does not include all costs of manufacture, for it does not include interest, depreciation and repairs, purchase of improved machinery, superintendence and office expenses. One maker who turned out 20,000 blocks (40 car loads) had a general expense of nearly 5 cts. per sq. ft., besides the above given 10½ cts. The selling price of 10-in. blocks averaged 21 cts. per sq. ft. of wall.

Cost of Concrete Buildings, References.—For further data on this subject consult "Concrete Construction" by Gillette and Hill.

Weight of Steel in Buildings.—Mr. H. G. Tyrrell states that weight of steel for buildings not more than 11 stories high is approximately as follows per sq. ft. of floor area:

	Per sq. ft. Lbs.
Apartment houses and hotels, with outside frame..	14
Apartment houses, without outside frame.....	9
Office buildings, with outside frame.....	23
Office buildings, without outside frame.....	16
Warehouses, with outside frame.....	28
Warehouses, without outside frame.....	13

Mr. Edward Godfrey gives the following:

The Phipps Power Building, Pittsburg, Pa., is 100 x 100 ft., 10 stories high, the first three stories being 24 ft., the rest being 13 ft. floor to floor. The live load was assumed at 250 lbs. per sq. ft. The total weight of steel and castings was 5,742,500 lbs., or 3.5 lbs. per cu. ft. of volume of building. Of this weight, 1,329,400 lbs. were in the columns, and 205,500 lbs. in the 28 cast iron column bases.

The following is the weight of steel in other Pittsburg buildings:

	Lbs. per cu. ft.
Arrott Building	1.8
Farmers Bank Building.....	2.3
Empire Building	2.1
Oliver Building	1.8

Mr. J. S. Branne gives the following estimate of the cost of the steel framework of an office building. The building is 50 x 100 ft., 16 stories high in the front and 13 stories high in the rear. The first story is 17 ft. high, and all others are 12 ft. high from floor line to floor line. All curtain walls (outside walls) are 13 ins. thick; inside tile partitions 4 ins. thick; floors of concrete. Live loads are assumed at 50 lbs. per sq. ft.; dead loads are 75 lbs. per sq. ft. Using outside dimensions, there are 745,000 cu. ft. in the building, and the steel weighs 795 tons, or 2.13 lbs. per cu. ft. of building. The price of the steel is estimated at 3 cts. per lb. in place.

Weight of Park Row Bldg., New York.—The main part is 26 stories high, surmounted by two 4-story towers. The area covered is 15,000 sq. ft. It rests on 3,500 piles. The basement was excavated 34 ft. below the street level.

The weight of the building is:

	Tons.
Steel	9,000
Masonry and other materials.....	56,200
Total	65,200

The estimated cost (in 1906) was \$2,000,000.

The total height from street level to top of cupolas on towers is 386 ft. The first story is 17 ft. high in the clear, the second is

13 ft., the third and fourth are 12 ft., the fifth is 11 ft., the rest are 9 ft. 11 ins. in the clear.

Weight of Steel Dome.—The steel dome of the Emporium building, San Francisco, is 102 ft. diameter and 52 ft. high, so mounted by a "lantern," 22½ ft. diameter and 15 ft. high. The weight is 200 tons.

Weight of Largest Steel Dome.—The largest steel dome in the world forms the roof of the West Baden Hotel, West Baden, Ind. Its span is 195 ft. c. to c. of piers. It is an aggregation of two-hinge arches, a drum at the center forming their common connection. The weight, including the steel framework and its covering is 475,000 lbs., or about 16 lbs. per sq. ft. of horizontal projection of roof surface.

Weight of Steel Arch Roof.—The Government building at the St. Louis Exhibition in 1904 contained steel roof trusses, which were three-hinged arches of 172 ft. span and 70 ft. rise. The trusses were spaced 35 ft. c. to c. The weight per square foot of horizontal projection was:

	Per sq. ft. Lbs.
Steel	13.1
Roofing	5.6
Tin covering.....	0.5
Total	20.2

Weight of Steel Fink Roof Trusses.—Mr. H. G. Tyrrell gives the following formula for the weight of steel roof trusses, based upon data of 146 separate trusses. The weight includes trusses complete, with rafter clips and shoe plates, but without ventilators.

$$W = \frac{S}{20} + \frac{12}{D}$$

W = weight (lbs.) per sq. ft. of ground.
 S = span in feet.
 D = distance (in feet) c. to c.

Steel Frame, St. Louis Coliseum.—Mr. E. W. Stern gives the following relative to a coliseum built in 1897. The steel frame for the roof is an oblong dome, 186 x 298 ft. The 4 main trusses are three-hinged arches, 176 ft. span. There are 6 radial trusses at each end of the building. A traveler derrick, 63 ft. long, 31 ft. wide, and 42 ft. high, carried two derricks used to erect the trusses. The total weight of steel was 9,500 tons. There were 4,188 days' labor spent on the work in the shops, and 3,550 days' labor for erection, the average number of men in the erecting force being 50.

Each of the main arches weighed 64,000 lbs.; each radial arch, 21,000 lbs.

Materials in Large Grain Elevator.—A fireproof grain elevator, having a capacity of 3,100,000 bushels, was built in 1900 for the Great Northern Ry., at West Superior, Wis. It is 124 x 364 ft. in

plan and 246 ft. high. It has 505 steel bins. It rests on a pile and grillage foundation. The following are the quantities:

Foundation and Walls in Main Story:	
Piles, number.....	4,570
Timber and sheet piling, M.....	380
Excavation, cu. yds.....	23,000
Masonry, cu. yds.....	1,500
Concrete, cu. yds.....	3,000
Cut stone, cu. ft.....	1,300
Brick, cu. ft.....	45,000
Superstructure:	
Structure below bins, tons.....	1,350
Bins proper, tons.....	6,500
Cupola, tons.....	1,450
Legs and spouts below bin floor, tons.....	450
Legs and spouts above bin floor, tons.....	350
Total steel, tons.....	10,600

There are 42 electric motors, having a total of 2,110 hp.

Cost of Fabricating and Erecting Steel Mill and Mine Buildings.—The following is a summary of data given in Ketchum's "Steel Mill Buildings," a book containing much excellent information on estimating steel work:

The drawings for steel mill buildings usually show only the dimensions of the "main members." The estimator usually calculates the weights of these main members and adds a percentage to provide for the weight of the "details." The "details" are the plates and rivets used in fastening the main members together. The weight of the "details" of trusses will commonly be 25 to 35% of the weight of the "main members," being usually nearer 25%. After computing the actual weights of details for a few buildings, the estimator will seldom blunder in computing by percentages.

In estimating the weight of corrugated steel, add 25% for laps where the side lap is two corrugations, and the end lap is 6 ins.; add 15% where the side lap is one corrugation and the end lap is 4 ins. Corrugated steel is usually made with corrugations $2\frac{1}{2}$ ins. wide (from ridge to ridge) and $\frac{5}{8}$ -in. deep. The thickness of the steel is usually given in U. S. Standard Gage. The following are the weights per 100 sq. ft. of black corrugated steel:

Gage, No.....	16	18	20	22	24	26	28
Lbs. per 100 sq. ft.....	275	220	185	138	111	84	69

Add 16 lbs. per 100 sq. ft. if the steel is galvanized.

The cost of steel mill buildings is divided into four items: (1) cost of steel; (2) cost of shop work; (3) cost of transportation, and (4) cost of erection. The price of structural steel may be found in current numbers of "Iron Age," published in New York. The price is now (1905) about 1.8 cts. per lb. at New York.

The following are actual shop costs, in a shop having a capacity of 1,000 tons per month, and with labor estimated at 40 cts. per hr., which includes also the cost of management and the cost of operating and maintaining the shop equipment:

Cost of shop-work :

Columns, made of 3 channels and 2 plates, 1,000 lbs.,....	0.8
Columns, made of single I-beam, or single angle.....	0.6
Columns, Z-bar.....	0.8
Columns, plain, cast iron.....	0.8 to 1.6
Riveted roof-trusses, 1,000 lbs. each.....	1.2
Riveted roof-trusses, 1,500 lbs. each..	1.0
Riveted roof-trusses, 2,500 lbs. each.....	0.8
Riveted roof-trusses, 3,500 to 7,500 lbs. each.....	0.6 to 0.75
Plate-girders, for crane girders and floors.....	0.6 to 1.2
Eye-bars, $\frac{1}{2}$ x 3 ins. x 16 to 20 ft.....	1.2 to 1.8
Eye-bars, large.....	0.5 to 0.8
Steel frame transformer building, 60 x 90 ft., with 20-ft. posts, pitch of roof $\frac{1}{2}$, 55,700 lbs. steel framework, including drafting.....	1.0
Smelter building, 270 tons, including drafting.....	0.86
Six gallowes frames, including drafting.....	1.0 to 2.0
Drafting design of "details" for .	
Ordinary buildings.....	0.1 to 0.2
Headworks for mines.....	0.2 to 0.3
Roof-trusses	0.3 to 0.4

With skilled labor at \$3.50 and common labor at \$2 per 9-hr. day, the cost of erecting small buildings is about 0.5 ct. per lb., or \$10 per ton, if trusses are riveted and other connections bolted.

The cost of erecting small buildings in which all connections are bolted is about 0.8 ct. per lb., or \$8 per ton.

The cost of erecting heavy machine shops, all material riveted, is about 0.45 ct. per lb., or \$9 per ton, including labor of painting.

The cost of erecting 6 gallowes frames was 0.65 ct. per lb., or \$13 per ton.

The cost of laying corrugated steel roof is about \$0.75 per square, or \$9 per ton for No. 20 steel, when laid on plank sheathing; it is \$1.25 per square, or \$15 per ton, when laid directly on the purlins; it is \$2 per square, or \$24 per ton, when laid with anti-condensation roofing. The erection of corrugated steel siding costs \$0.75 to \$1.00 per square, or \$9 to \$13 per ton for No. 20 steel.

Cost of Erecting the Steel in Buildings.—The costs are given in tons of 2,000 lbs. On a four-story, fireproof hospital the cost of erecting the steel and cast iron was \$4.50 per ton; hand derricks were used, and the work was all done by common laborers, at \$1.50 per day. With a steam derrick the cost might have been reduced to \$3.50 per ton. On a three-story business block, under the same conditions as before, the store fronts were erected for \$5 per ton.

On a large railroad machine shop, with structural steel workers at 40 cts. per hr., the cost of erecting was \$8 per ton. In this case the work was all heavy, the lightest truss weighing 5 tons. On train sheds, and where lighter sections were used, and where there were more field rivets to the ton, the cost was \$10. Ordinarily there are about 10 field rivets to the ton, and it is safe to allow 10 cts. each, or \$1 per ton for riveting alone. There are buildings in which 25 field rivets per ton are required. The foregoing costs of steel erection include unloading from cars, setting derricks and scaffolding.

The cost of erecting large electric cranes is about \$3 per ton if put in place directly from the cars. Add \$1.50 per ton if unloaded from cars before erecting.

The steel frames of modern office buildings are usually erected by derricks high enough to erect two or three floors without shifting. The cost of erecting and riveting the steel is \$10 to \$15 per ton. The trusses of small roofs can be erected cheaply by the use of one or two gin poles.

Area of Passenger Stations.—In the Proc. Am. Ry. Eng. and Mn. of Way Assoc., 1904, a committee report gives the average area of passenger stations for cities of 10,000 to 15,000 population on 31 different railways, as follows:

	Sq. ft.
Waiting rooms.....	1,160
Toilet rooms.....	186
Baggage rooms.....	433
Ticket offices.....	218
Total	1,997

Such a station would measure about 24 x 84 ft. inside.

Cost of Moving a Frame Dwelling House.*—This building was moved at Secaucus, N. J., during the month of July, 1906, under contract, to make room for freight yard extensions. The house (weighing about 50 tons) was 30 ft. square, two stories in height, with a one-story extension in the rear 12 x 18 ft., all resting upon brick piers standing 2 ft. above level of ground. The building was first raised about 14 ins. with jack screws and blocking. Several long 12-in. x 12-in. timbers were then placed under the joists lengthwise and crosswise, all properly cleated and fastened, care being taken to support the two chimneys. The movement was accomplished with windlass, team, driver and about 1,000 ft. of 2-in. manilla rope passed through the blocks, the building sliding forward upon greased supports of way of long timbers blocked up to the proper height. It was moved forward a distance of 115 ft., then turned about 90° and pulled backward a distance of 435 ft. to its new location, making a total distance traveled of 548 ft.

During the moving the force was kept busy greasing timbers with soap and carrying blocking forward. At intervals the moving was stopped, the team detached from the windlass and used to haul the long timbers ahead. In moving it was necessary to cross over two roads and pass under three lines of light and telephone wires. Men were stationed upon the top of the house to lift the wires over the roof and chimneys. Previous to moving, the building was strengthened to prevent racking, by placing several temporary bents in rooms on first floor. The only damage occurred from plaster cracking around chimneys, and this was slight. The tenants occupied the house during the moving period.

Wages for laborers were \$2.00 per day, hours from 7 a. m. to 6 p. m., and half days on Saturday, for which they received a full day's pay. The foreman received \$3.50 per day, utility man \$3.00 per day, night watchman \$2.00 per day. Teams were paid at the

**Engineering-Contracting*, Oct. 30, 1907.

rate of \$1.50 per day and 75 cts. per day was paid for a horse. During the moving drivers worked as laborers.

The actual labor cost is divided as follows:

		Per cent.
Hauling blocking, lumber and tools (9 miles for round trip).....	\$ 27.00	9.1
Placing and removing blocking timbers, raising and lowering before and after moving	102.00	34.5
Moving building (548 ft.).....	166.75	56.4
Total moving.....	\$295.75	100.0

The time occupied in doing the work including the time lost for Sundays, holidays and rain was 24 days. Actual number of days worked was 16. The total cost of this moving to contractor was \$357.50, the extra \$61.75 (added to \$295.75) being wages paid to foreman, 2 drivers and watchman for Sundays, holidays and days lost on account of rain.

For the above information we are indebted to Mr. A. L. Moorehead, C. E.

References.—Any one engaged in estimating the cost of very many buildings will do well to consult Arthur's "Building Estimator," Tyrrell's "Mill Buildings," Ketchum's "Steel Mill Buildings," and Klidder's "Architects' and Builders' Pocket Book."

The prices of hardware may be obtained from "The Iron Age Standard Hardware List" (\$1), published by The Iron Age, New York City. The current discounts are given in The Iron Age, a copy of which costs 10 cts.

The prices of lumber are quoted weekly in such papers as the "New York Lumber Trade Journal." Different mills issue catalogs giving prices of mill work.

SECTION XI.

RAILWAYS.

Cross-References on Cost of Grading.—The reader is referred to the Earth Excavation and Embankment Section, and to the Rock Excavation Section, for costs of grading. The cost of tunneling is given on page 1180, etc.

Cross-References on Bridges, Culverts and Buildings.—For data on these subjects, consult the "Bridges and Culvert Section," the "Timberwork Section," and the "Building Section," of this book. Use the index for the item in question.

Cost of Transporting Men, Tools and Supplies on Railroads for Grading.*—In carrying on construction work it is the custom of railroads to charge to construction certain rates of fares on the men employed, and freight on tools and supplies. This charge against the new work is credited to the operating department. Engineers in the employ of a railroad company in making up estimates for new work must include these charges, else the cost of the work is likely to overrun the estimate. To do this there must be some basis of the amount of work that a man, horse and machine will do in a given time, and an approximate tonnage of machines and supplies needed to excavate a given unit.

The same assumption applies to track work, bridges and buildings, but in this article we consider only the grading of a railroad.

The following figures have been used by one of the editors of this journal in estimating the cost of railroad construction. The figures of work done, and men, horses and tools and supplies needed are based on large jobs of construction, and are safe averages. The fares for men and the freight rates are those ordinarily charged by railroads for such movement of men and freight.

The costs follow:

One horse plus $1\frac{1}{2}$ men readily excavate and move 15 cu. yds. of earth per day. Hence allow 360 cu. yds. per month per horse and 250 cu. yds. per month per man.

One man requires transportation at 1 ct. per mile, and freight on 200 lbs. of bedding, cooking utensils, tents, small tools, etc.

**Engineering-Contracting*, July 8, 1908.

Hence for 100 miles transportation each way, or 200 miles round trip, we have

200 passenger miles at 1 ct.....	\$2.00
1/10 ton bedding, etc., 200 miles at 1/2 ct. per ton mile.....	.10
Total	\$2.10

Since one man will excavate 250 cu. yds. per month, it costs \$2.10 divided by 250, or 0.8 ct. per cu. yd., if the job lasts only one month; but if the job lasts four months it costs 0.8 ct. divided by 4, or 0.2 ct. per cu. yd., because in that time a man will move 4 times 250 cu. yds., or 1,000 cu. yds., and will only require transportation once at a cost of \$2.10. Other months are in proportion. For any other haul than 100 miles multiply accordingly.

Each horse requires the following equipment:

	Lbs.
1/2 wheel scraper, at 500 lbs.....	250
1/2 wagon, at 2,000 lbs.....	1,000
Tents, harness, etc.....	250
Total	1,500

Allowing 18 horses per car of 24,000 lbs., each horse stands for freight equivalent to 1,500 lbs., hence:

Equipment for each horse.....	1,500
Weight of horse.....	1,500
Total, 1 1/2 tons or.....	3,000

For each 100 miles of haul we have, therefore, 200 miles round trip; hence 200 miles \times 1 1/2 tons \times 0.4 ct. = \$1.20.

Since each horse moves 360 cu. yds. per month, we have \$1.20 \div 360, or 0.3 ct. per cu. yd., if the job lasts only one month. But if the job lasts four months we have 1/4 of 0.3 ct., or 0.075 ct. per cu. yd. Other lengths of time and other hauls are in proportion.

Each horse consumes 1/2 ton of food per month; hence if food is hauled 100 miles we have 1/2 ton \times 100 miles \times 0.4 ct. = 20 cts.

Since the horse moves 360 cu. yds. per month, we have 20 cts. \div 360, or 0.05 ct. per cu. yd. for each 100 miles of haul.

Summing up, we have the following costs:

Duration of work.	Cost per cu yd. for transportation 100 miles and return.			
	Men. Cts.	Horses. Cts.	Food. Cts.	Total. Cts.
1 mo.....	0.80	0.20	0.05	1.15
4 mos.....	0.20	0.08	0.05	0.33
6 mos.....	0.13	0.05	0.05	0.23
8 mos.....	0.10	0.04	0.05	0.19
12 mos.....	0.07	0.03	0.05	0.15

Note.—If the haul is 300 miles, multiply by 3. If the haul is 500 miles, multiply by 5. If the haul is 1,000 miles, multiply by 10.

The above is for work done by wheel scrapers and wagons and carts, but for steam shovel work the following would be the approximate cost for transportation:

	Tons.
1 shovel.....	70
60 dump cars.....	120
Rail	65
Cross ties (6"x6"x6').....	75
Three small locomotives.....	35
Pumps, drills, etc.....	35
Total	400
400 tons X 100 miles X 0.4 ct. = \$160.	

Such a shovel as this will average at least 20,000 cu. yds. per month, hence we have $\$160 \div 20,000$, or 0.8 ct. per cu. yd. for transporting the shovel 100 miles. This is equivalent to 1.6 cts. for transporting the shovel the round trip of 200 miles, when the job lasts only one month. For four months the cost would be $\frac{1}{4}$ of 1.6 cts., or 0.4 ct. per cu. yd. Other months would be correspondingly in proportion.

Such a shovel does not consume more than 60 tons of fuel and supplies per month; hence we have 60 tons X 100 miles X 0.4 ct. = \$24. Since with this 60 tons of fuel there are 20,000 cu. yds. excavated, we have $\$24 \div 20,000$, or 0.12 ct. per cu. yd. With such a shovel there will never be more than 40 men engaged in operating the shovel, operating the dump cars and trains, as well as in making temporary roadways and repairing equipment; hence each of these 40 men averages 500 cu. yds. per month, which is double the output where men are working with wheel scrapers, carts, etc., as above given; therefore the cost of transporting men per cu. yd. on shovel work is approximately one-half the amount given in the previous table.

Summing up we have the following:

		Cost per cu yd. for transportation 100 miles and return.			
Duration of work.		Shovel. Cts.	Men. Cts.	Fuel. Cts.	Total Cts.
1 mo.....		1.60	0.40	0.12	2.12
4 mos.....		0.40	0.10	0.12	0.62
6 mos.....		0.26	0.07	0.12	0.45
12 mos.....		0.13	0.03	0.12	0.28

The above is for a haul of 100 miles, and for any other hauls multiply according to the length of haul.

If the workmen are of a restless disposition, and remain only a month or two on the job before quitting, the cost of their transportation varies not with the length of the job but with the average time they remain on it. When they quit of course their return fare is not paid.

Cost of Three Short Single-Track Tunnels.*—Short tunnels are usually constructed at less cost than long tunnels, not only because of the less cost of hauling and "muck" and the ease of ventilating the tunnel, but because a very inexpensive plant can be used. In limestone and sandstone formations the present contract prices average about

**Engineering-Contracting*, Aug. 21, 1907.

\$45 per lin. ft. of single-track tunnel for all lengths up to 1,000 ft. or so, even where common laborers receive \$2.25 a day. The following data give the cost (at contract prices) of three tunnels built in the West, and, both as to prices and as to quantities, these examples will be useful to engineers and contractors:

TUNNEL No. 1 (900 Lin. Ft.).

	Per lin. ft.
Excavating tunnel.....	\$45.00
2.7 cu. yds. enlargement for lining, at \$3.00.....	8.10
350 ft. B. M. timber lining, at \$20.....	7.00
5.7 lbs. iron, at \$0.03.....	0.17
Total	\$60.27

TUNNEL No. 2 (600 Lin. Ft.).

	Per lin. ft.
Excavating tunnel.....	\$45.00
2.7 cu. yds. enlargement, at \$3.00.....	8.10
370 ft. B. M. lining, at \$20.00.....	7.40
5.5 lbs. iron, at \$0.03.....	0.17
Total	\$60.67

TUNNEL No. 3 (400 Lin. Ft.).

	Per lin. ft.
Excavating tunnel.....	\$42.50
2.8 cu. yds. enlargement, at \$3.00.....	8.40
400 ft. B. M. lining, at \$20.00.....	8.00
7.4 lbs. iron at \$0.02.....	0.22
Total	\$59.12

In addition to the above costs which are based on the contractor's final estimate, there was a cost of \$3 per lin. ft. (or about 5%) for engineering and superintendence, and a cost of \$0.50 per lin. ft. for train service.

Cost of the Stampede Tunnel.*—Mr. Charles W. Hobart gives the following data on the Stampede or Cascade Tunnel of the Northern Pacific R. R. Bids were opened in New York Jan. 21, 1886, for a single-track tunnel, 9,844 ft. long, to be completed in 28 mos. Of the 12 bids, that of Mr. Nelson Bennett was lowest and was accepted. A forfeit of \$100,000 and 10% of the contract price for failure to complete within the time was required. Mr. Bennett telegraphed his general manager to gather men and clear a road to get the machinery on the ground. The plant was purchased for \$100,000 in New York and shipped. It consisted of 5 engines, 2 water wheels, 5 air compressors, 5 boilers of 70-hp. each, 4 fans, 2 electric arc light plants, 2 miles of 6-in. wrought iron, 2 miles of water pipe, 2 machine shop outfits, 36 air drills, 2 locomotives, 60 dump cars, 2 saw mills and other necessities. This plant had to be transported on wagons and sleds from Yakima, Wash., a distance of 82 miles to the east portal of the tunnel and 87 miles to the west portal. The first wagon loads started Feb. 1, and the first boiler

*Gillette's "Rock Excavation."

Feb. 23. By June 19 the plant for the east portal, and by July 15 the plant for the west portal had reached its destination. On Feb. 13 hand drilling was begun on the east portal and 411 ft. of tunnel had been driven when the machines began June 19. On March 15 hand drilling started at the west end and by Sept. 1, when the machines started, 488 ft. had been driven. The last 15 miles of the hauling before reaching the mountains was in mud, so that wagons were hauled by block and tackle, planks being laid down in front of the wheels and taken up as fast as the wagons passed. About one mile a day was covered in this way. When the mountains were reached sleds were improvised and hauled by block and tackle with teams. Wagons lightly loaded with provisions traveled 12 miles a day.

The cost of clearing the way and getting the machinery and materials on the work was \$125,000,* and 6 mos. time was required. The tunnel was to be 9,950 ft. long, 16½ x 22 ft. in the clear; 900 ft. had been driven by hand, leaving 9,050 ft. to be driven in 22 mos.

An 8-ft. heading was driven along the top of the tunnel and was kept 30 ft. ahead of the bench. The tunnel was timbered as work progressed. The average number of men employed, after the machinery was installed, was 350. They worked 10-hr. shifts, receiving \$2 50 to \$5 a day. Contractor boarded men at 75 cts. a day. A bonus of 25 cts. a day was paid each laborer for every foot gained during the month over the necessary average of 13.6 ft. a day in both headings combined, and each driller received a bonus of 50 cts. per day per ft. gained. Every day of the year was worked, requiring two shifts of 75 men each, beside the engineers, firemen, carpenters, machinists, etc., making a monthly payroll of \$30,000. The best month's progress was April, 1888, when a total advance of 540 ft. was made in the two headings, or 9 ft. a day per heading. The average progress for 21½ mos., with power drills, was 413 ft. per month for the two headings. On May 3, 1888, the headings met, and on May 14 the excavation was completed, 7 days before the time limit. The track was laid in two days more and on May 22 the first regular train passed through the tunnel.

The total explosives used were 309,625 lbs., as follows:

	No. of 50 lb. boxes.
Giant No. 1, 80 per cent.....	408¾
Giant No. 2, 45 per cent.....	2,123¼
Hercules No. 1, 60 per cent.....	1,609¼
Hercules No. 2, 45 per cent.....	1,781¾
Nitro glycerin No. 2.....	233
Forcite No. 2.....	41¼
Total No. of 50-lb. boxes.....	6,192

The average price of all explosives was \$10 a box, or 20 cts. per lb. The total number of men killed in the two years was 13. The following data were furnished by Mr. Andrew Gibson, Assistant Engineer. The American center-cut system of blasting was used;

Wages were \$2.50 for laborers, which is a high price.

20 to 22 holes, 12 ft. deep, being drilled in the heading, and about 18 holes in the bench. Each drill, in medium hard rock, would make 6 or 7 holes in 5 hrs., although at times in an exceedingly hard layer 15 hrs. would be required. About 400 lbs. of dynamite were used at each blast in each of the headings and benches. This would break 8 to 12 lin. ft. of tunnel, although in very hard rock at times only half this progress was made. The rock is basaltic,* with a dip of 5° to the west. It required immediate timbering, which delayed the drillers and muckers about 25% of the time. During the period of hand drilling there were 17 men, with about 28 muckers, employed in each heading, and 4 lin. ft. of tunnel in 24 hrs. were averaged. During the period of air drilling, 10 drills were used, 5 in each end, and the progress was 6.9 ft. in 24 hrs. per heading, or 207 ft. per mo. of 30 days. While the contract size of the tunnel was 18½ ft. wide, and 22 ft. from subgrade to face of arch, the timbered sections had to be excavated 19½ ft. wide by 24 ft. high, thus requiring 15.7 cu. yds. of excavation per lin. ft. where timbering was used, as against 12.36 cu. yds. where no timber was used. Timbers were 12 x 12 ins., except the 8 x 12-in. sills. Five segments were used in the arch, lagged with 4 x 6-in. pieces. Bents were spaced 2 to 4 ft. Water gave no trouble.

Mules were used for hauling up to the first half mile; then small locomotives, which hauled 8 to 12 cars. A "go-devil" or platform on wheels was used to great advantage in loading cars. The men wheeled the rock on plank runways from the heading to the "go-devil," dumping directly into cars below; and the muckers on the heading never interfered with those on the bench. It was also a great convenience in timbering. Before blasting the drills were loaded upon the "go-devil," and it was pushed back some distance from the face. Endless belt conveyors for removing muck to the "go-devil" were contemplated, but they were never used, as with the large force of men at work they would have been in the way.

The swelling of the shale on exposure often reduced a 12-in. timber to 4 ins.; hence it was necessary to line the tunnel with masonry. Concrete side walls and a brick arch were used for lining. The concrete mortar was brought in on cars and run back of the forms through spouts, without shoveling; then the broken rock was shoveled into the mortar from a flat car.

The total cost of the tunnel to the N. P. R. R. under Mr. Bennett's contract (which did not include masonry lining) was \$118 per lin. ft. Mr. Bennett's brother was the superintendent of the work. The actual cost of tunnelling the west end during the month of November, 1887, was \$75.75 per ft. for the 258 ft. driven, distributed as follows:

*Elsewhere it is stated that the rock was shale.

Labor.

Superintendent, $\frac{1}{2}$ mo., at \$500.....	\$ 250.00
Superintendent, 1 mo., at \$250.....	250.00
Master mechanic, $\frac{1}{2}$ mo., at \$150.....	75.00
Engineers, 4 x 30 = 120 days, at \$4.....	480.00

64 $\frac{1}{2}$ cords wood, at \$3.....	192.50
240 tons coal, at \$4.....	960.00
900 caps, at 1 ct.....	9.00
14,400 ft. fuse, at 1 ct.....	144.00
13,800 lbs. dynamite, at 16 cts.....	2,208.00

Total materials for 258 ft., at \$16.80 per ft.\$ 4,342.50

Plant

6 per cent of \$50,000 plant, 1 mo.....	\$ 250.00
1/28 of 75 p. c. depreciation * of \$50,000 plant.....	1,329.28
10 p. c. on all above to cover all possible omissions.....	†1,776.72

Total plant charges for 258 ft., at \$13.05..\$ 3,356.00

*Note that a liberal but not unusual allowance is made for plant depreciation.

†This 10 per cent, practically covers the cost of installing the plant.

Summary of cost per ft.

Labor	\$45.90
Material	16.80
Plant	13.05
Total	\$75.75

During this month the entire length was lined with timber, the rock being a soft basaltic rock that drills well but goes to pieces rapidly on exposure. There were no accidents or delays.

On the east end during this same month, with an equal force, the progress was 246 ft., at a cost of \$72.70 per ft. It will be noted that wages were high. It will also be noted that the cost of hauling and installing the plant is not included, although a liberal allowance is made for plant depreciation and in the 10% added to cover omissions.

The contractor received for his month's work on the west end of the tunnel:

258-ft. tunnel, standard sections, at \$78.....	\$20,124
862 cu. yds. extra excav., at \$4.50.....	3,879
78,000 ft. B. M. lining, at \$35.....	2,730

258 ft. of tunnel, timbered, at \$103.62.....\$26,733

The best month's record in driving a heading was 274 ft. but, as before stated, the average progress with the air drills was 207 ft. per mo. per heading, although in the month of November, 1887, 258 ft. were progressed on the west end, which was 25% better than the average progress. Assuming that 15.7 cu. yds. were excavated per lin. ft. of tunnel, the total excavation at the west end for November was 4,052 cu. yds. It is probable that the 862 cu. yds. extra excavation, above given, are included in this estimate, because the "standard section" differed from the timbered section by 3.2 cu. yds. per lin. ft., and in 258 ft. this would amount to 852 cu. yds. On this assumption (of 4,052 cu. yds.) the labor cost \$2.92 per cu. yd.; the materials, \$1.07 per cu. yd.; and the plant, \$0.83 per cu. yd.; total, \$4.82 per cu. yd. for the best month's work.

Further data on this tunnel are given in the following paragraphs.

Cost of the Stampede Tunnel and its Masonry Lining.*—The Stampede Tunnel on the Northern Pacific Ry. is 2,844 ft. long and was built in 1886 to 1888 by contract. The contract work included the excavation of this tunnel and the timber lining. Subsequently this timber lining was replaced with a masonry lining by the railway company's own forces. This article gives in detail the cost of the permanent masonry lining. To make the cost figures complete, however, we itemize the contract costs of the original construction as follows:

	Per lin. ft.
Excavation, standard section, at \$78.....	\$ 78.00
Extra excavation, 3.2 cu. yds., at \$4.50.....	14.40
Timber lining, 305 ft. B. M., at \$35.....	10.68
Traffic charges.....	0.77
Total	\$103.85
Ballast	0.90
Track materials.....	1.23
Track laying.....	0.18
Track surfacing.....	0.16
Engineering	5.00
Total	\$111.22

The above figures are the contract costs to the Northern Pacific Ry.

**Engineering-Contracting*, June 3, 1903.

The permanent masonry lining work, whose cost is given here, was begun June 16, 1882, and completed Nov. 16, 1896, the progress in lineal feet per year being as follows:

	Walls.	Arch.
1889	1,176
1890	1,280	538
1891	2,549	871
1892	5,028	1,402
1893	2,930	911
1894	3,229	2,812
1896	2,301	2,887

The side walls were of concrete and the arch was of brick, there being 30,259 cu. yds. of concrete side walls and 18,426 cu. yds. of brick arch, or a total of 48,685 cu. yds. of masonry lining in the 9,311 lin. ft. that were lined. There were, therefore, $5\frac{1}{4}$ cu. yds. of concrete side walls and 2 cu. yds. of brick arch, or a total of $5\frac{1}{4}$ cu. yds. per lin. ft. of tunnel.

The average cost of the lining was as follows:

<i>Concrete Side Walls:</i>	Per cu. yd.	Per lin. ft.
Cement, at \$2.90 per bbl.....	\$4.27	\$13.95
Rock, at 31 cts. per cu. yd.....	0.24	0.80
Sand, at 21 cts. per cu. yd.....	0.12	0.40
Traffic charges	0.35	1.13
Train service	0.96	3.12
Labor	2.10	6.87
False work	0.08	0.27
Tools, lights, etc.....	0.10	0.33
Engineering and superintendence..	0.16	0.53
Total	\$8.38	\$27.40

<i>Brick Arch:</i>	Per cu. yd.	Per lin. ft.
Cement, at \$2.90 per bbl.....	\$ 2.93	\$ 5.80
Brick, at \$7.12 per M	3.56	7.04
Rock backing, at 59 cts. per cu. yd.	0.41	0.81
Sand, at 40 cts. per cu. yd.....	0.14	0.27
Traffic charges	0.36	0.71
Train service	1.21	2.39
Labor	4.20	8.32
Falsework	0.22	0.43
Tools, lights, etc.....	0.21	0.41
Engineering and superintendence..	0.25	0.50
Total	\$13.49	\$26.68

Since the concrete side walls cost \$27.40 per lin. ft. and the brick arch cost \$26.68, the total cost was \$54 per lin. ft. of tunnel, which, if added to the \$111 above given, makes a grand total of \$165 per lin. ft. Had the masonry lining been built in the first place, the cost would have been considerably less.

The item of "traffic charges" covers freight on materials at 1 ct. per ton-mile. The item of "train service" covers hauling of sand, rock, etc., with a work train.

The cost of this lining was very much higher during the first years of the work. This was due partly to the greater thickness of the lining used at first, but it was principally due to the inexperience

ence of the men and the higher cost of materials. The following table shows the cost by six-month periods:

6 mos. ending.	—Brick Arch.—		—Concrete Wall.—		Total per lin. ft.
	Lin. ft.	Cost per lin. ft.	Lin. ft.	Cost per lin. ft.	
June 30, 1889.....	33	\$61.72
Dec. 31, 1890.....	1,143	61.72
June 30, 1890.....	257	63.24	\$124.96
Dec. 31, 1890.....	281	63.24	1,230	56.92	120.16
June 30, 1891.....	600	51.64	733	40.94	92.58
Dec. 31, 1891.....	271	51.64	1,816	40.94	92.58
June 30, 1892.....	517	34.90	2,422	22.06	56.96
Dec. 31, 1892.....	886	27.13	2,616	19.80	46.93
June 30, 1893.....	496	25.35	2,219	19.48	44.83
Dec. 31, 1893.....	416	20.96	711	19.46	40.36
June 30, 1894.....	904	20.21	3,229	16.55	36.76
Dec. 31, 1894.....	1,898	19.40
June 30, 1895.....	1,225	18.90	2,187	18.04	36.94
Dec. 31, 1895.....	114
Total	9,311		18,503		

The foregoing shows the progressive decrease in the cost per lineal foot. The following table shows the decrease in the cost per cubic yard:

Six mos. ending.	Brick Arch.		Concrete Walls.	
	Cu. yds.	Cost per cu. yd.	Cu. yds.	Cost per cu. yd.
June 30, 1889.....	33	\$12.26
Dec. 31, 1889.....	2,876	12.26
June 30, 1890.....	617	\$26.35

The cost of lining the tunnel during the six months ending Dec. 31, 1892, represents about an average of the whole job. It was as follows:

CONCRETE SIDE WALLS.

Materials:	Per cu. yd.
Cement, 1.5 bbls., at \$2.36.....	\$3.54
Sand, 0.33 cu. yd., at 36 cts.....	0.12
Rock, 0.5 cu. yd., at 55 cts.....	0.28
Dry rock backing, 0.04 cu. yd., at 55 cts.....	0.02
Total	\$3.96
Traffic Charges:	
Cement	\$0.24
Sand	0.17
Rock	0.18
Total	\$0.59

Work Train Service:

Hauling concrete, removing old timbers and excavating material, 0.081 day of work train, at \$26.90.....\$0.83

Labor:

Mixing cement dry, 0.104 day, at \$2.50.....\$0.26

Building walls, 0.247 day, at \$2.84..... 0.70

Removing timbers, excavating and preparing panel for concrete, 0.226 day, at \$2.83..... 0.64

Placing rock backing, 0.02 day, at \$2.50..... 0.05

Total\$1.65

Engineering, Superintendence and Miscellaneous:

Engineering\$0.29

Falswork, timber and iron..... 0.06

Lights, wear on tools, etc..... 0.03

Interest and depreciation of plant, 10% per annum on \$1,500, for 3½ mos..... 0.01

Total\$0.39

Total per cu. yd. in place.....\$7.42

The proportions were 1 cement, 3 sand and 5 rock. The dimensions of each side wall were 2 ft. 3 ins. thick and 16 ft. high. There were 1.83 cu. yds. of concrete per lin. ft. of side wall, or 2.66 cu. yds. per lin. ft. of tunnel. The average daily force, not including the work train crew, was:

1 foreman, at \$135 per mo.

1 foreman, at \$3.75 per day.

1 foreman, at \$3.25.

3 carpenters, at \$3

22 laborers, at \$2.50.

4 laborers, at \$2.

The average daily progress was 38.75 cu. yds. per day.

The average daily force "building the side walls" was:

1 foreman, at \$135 per mo.

2 foremen, at \$3.25 per day.

4 carpenters, at \$2.

12 laborers, at \$2.50.

The average daily force engaged in "removing timbers, excavating, etc.":

1 foreman, at \$135 per mo.

2 foremen, at \$3.75 per day.

2 carpenters, at \$3 per day.

14 laborers, at \$2.50 per day.

The cost of the brick arch during the same period was:

BRICK ARCH.**Materials:****Per cu. yd.**

Brick, 526, at \$7 per M.....\$ 2.68

Cement, 1.18 bbls., at \$2.40..... 2.83

Sand, 0.263 cu. yd., at 83 cts..... 0.21

Dry rock backing, 0.483 cu. yd., at 75 cts..... 0.36

Total materials\$ 7.08

Tragic Charges:

Brick	\$ 0.89
Cement	0.19
Sand	0.13
Total	\$ 1.21

Work Train Service:

Hauling brick and cement and removing debris and old timber, 0.046 day, at \$26.70.....	\$ 1.23
--	---------

Labor:

Mixing mortar and building arch, 0.78 day, at \$4.06.....	\$ 3.16
Placing rock, backing, 0.185 day, at \$2.68.....	0.36
Moving centers, preparing for work and removing timber 0.383 day, at \$2.87.....	1.10
Total	\$ 4.62

Engineering, Superintendence and Miscellaneous:

Engineering and superintendence.....	\$ 0.44
Falswork, timber and iron.....	0.05
Changing lights, wear on tools, etc.....	0.04
Interest and depreciation of plant, 10% per annum on \$1,500, for 2½ mo.	0.02
Total	\$ 0.55
Total per cu. yd.....	\$14.69

The brick arch was 5 rings thick, or 1 ft. 9 ins., and 28½ ft. around the arc. The bricks were 2½ x 3¾ x 8 ins. There were 1.85 cu. yds. of brick masonry per lin. ft. of tunnel, making the cost \$27.13 per lin. ft. for the brick arch. The average daily progress was 25.9 cu. yds., with the following force, not including work train crew:

- 1 foreman, at \$135 per mo.
- 1 brick mason foreman, at \$6.50 per day.
- 1 foreman, at \$3.75 per day.
- 1 foreman, at \$3.25 per day.
- 7 brick masons, at \$6 per day.
- 2 carpenters, at \$3 per day.
- 26 laborers, at \$2.50 per day.

The average gang engaged in "mixing mortar and building arch" was:

- 1 foreman, at \$135 per mo.
- 1 foreman, at \$3.75 per day.
- 2 brick foremen, at \$6.50 per day.
- 7½ brick masons, at \$6 per day.
- 1 carpenter, at \$3 per day.
- 31 laborers, at \$2.50 per day.

The average gang engaged in "placing rock backing" was:

- 1 foreman, at \$135 per mo.
- 2 foremen, at \$3.25 per day.
- 4 carpenters, at \$3 per day.
- 30 laborers, at \$2.50 per day.

The average gang engaged in "removing timbers, excavation, etc.," was:

- 1 foreman, at \$135 per mo.
- 2 foremen, at \$3.75 per day.
- 5 carpenters, at \$3 per day.
- 12 laborers, at \$2.50 per day.

As above stated, the cost during the last year of the work was very much reduced.

During the six months ending June 30, 1895, the cost of lining was as follows:

CONCRETE SIDE WALLS.

<i>Materials:</i>	<i>Per cu. yd.</i>
Cement, 1.33 bbls., at \$3.25.....	\$2.99
Sand, 0.47 cu. yd., at 18 cts.....	0.08
Rock, 0.79 cu. yd., at 39 cts.....	0.31
Total	\$3.38
<i>Work Train Service:</i>	
Hauling concrete, removing debris and old timber, 0.023 day, at \$22.90	\$0.51
<i>Labor:</i>	
Mixing cement, 0.07 day, at \$2.14.....	\$0.
Building walls, 0.28 day, at \$2.40.....	0.66
Removing timbers, excavating and preparing panel for concrete, 0.21 day, at \$2.62.....	0.54
Total	\$1.85
<i>Engineering and Miscellaneous:</i>	
Engineering and superintendence.....	\$0.23
Falsework, timber and iron.....	0.06
Tools, lights, etc.....	0.10
Interest and depreciation of plant, 10% per annum of \$1,500, for 3 mos.....	0.01
Total	\$0.39
Total per cu. yd.....	\$5.64

It will be noted that "traffic charges" (freight on the materials for concrete) appear to have been omitted.

The proportions of the concrete were 1:3:5. The side wall was 2 ft. 7 ins. thick by 16 ft. high, and each side wall contained 1.6 cu. yds. per lin. ft. The average progress per day was 46 cu. yds., and the working force was as follows:

- 1 foreman, at \$112.50 per mo.
- 1 foreman, at \$90 per mo.
- 1 foreman, at \$3.50 per day.
- 1 blacksmith, at \$3 per day.
- 2 carpenters, at \$3 per day.
- 19 laborers, at \$2.25 per day.
- 7 laborers, at \$1.75 per day.

The cost of the brick arch during the same period was as follows:

BRICK ARCH.

<i>Material.</i>	<i>Per cu. yd.</i>
Brick, 500, at \$6.86.....	\$ 3.18
Cement, 0.98 bbl., at \$2.25.....	2.21
Sand, 0.34 cu. yd., at 28 cts.....	0.09
Total	\$ 5.48
<i>Work Train Service:</i>	
Hauling material, debris, etc., 0.037 day, at \$24.25.....	\$ 0.91
<i>Labor:</i>	
Mixing mortar and building arch, 0.57 day, at \$3.15.....	\$ 1.80
Placing rock backing, 0.09 day, at \$2.29.....	0.21
Removing old timbers, excavating and preparing for arching and moving centers, 0.32 day, at \$2.48.....	0.80
Total	\$ 2.81
<i>Engineering and Miscellaneous:</i>	
Engineering and superintendence	\$ 0.23
Falsework, timber and iron.....	0.09
Tools, lights, etc.....	0.20
Interest and depreciation of plant, 10% per annum on \$1,500, for 3 mos.....	0.02
Total	\$ 0.54
Total per cu. yd.....	\$10.21

It will be noted that the item of "traffic charges" appears to have been omitted.

There were 5 rings of brick in the arch, giving a thickness of 1 ft. 9 ins., and the length of the arc was 28 ft. There were 1.85 cu. yds. of brick masonry per lin. ft. of tunnel. The bricks were $2\frac{1}{2} \times 3\frac{3}{4} \times 8$ ins.

The average progress per day was 44.3 cu. yds. with the following force:

- 1 foreman, at \$112.50 per mo.
- 1 foreman, at \$90 per mo.
- 1 foreman, at \$3.50 per day.
- 1 brick mason foreman, at \$5.50 per day.
- 2 brick masons, at \$5 per day.
- 1 carpenter, at \$3 per day.
- 1 blacksmith, at \$3 per day.
- 27 laborers, at \$2.25 per day.

The gang when engaged in "mixing mortar and building arch" was as follows:

- 1 foreman, at \$112.50 per mo.
- 2 foremen, at \$3.50 per day.
- 2 mason foremen, at \$5.50 per day.
- 1 timekeeper, at \$60 per mo.
- 17 brick masons, at \$5 per day.
- 1 blacksmith, at \$3 per day.
- 25 laborers, at \$2.25 per day.

The gang when engaged in "placing rock backing" was as follows:

- 1 foreman, at \$112.50 per mo.
- $\frac{1}{2}$ timekeeper, at \$60 per mo.
- $\frac{1}{2}$ blacksmith, at \$3 per day.
- $\frac{1}{4}$ carpenter, at \$3 per day.
- 22 laborers, at \$2.25 per day.

The gang when engaged in "removing old timbers, etc.," was as follows:

- 1 foreman, at \$112.50 per mo.
- 2 foremen, at \$90 per mo.
- 1 timekeeper, at \$60 per mo.
- 3 blacksmiths, at \$3 per day.
- 1 carpenter, at \$3 per day.
- 17 laborers, at \$2.25 per day.

Cost of the Cascade Tunnel.—The tunnel is 12,813 ft. long through the Cascade Mountains on the line of the Great Northern Ry. The width in the clear is 16 ft., and the height from top of rail to bottom of arch is 21 $\frac{1}{2}$ ft. It was begun, from two headings, Aug. 20, 1897, and completed Oct. 13, 1900. A top heading, 10 x 20 ft., was driven from each end; and the bench was taken out in two lifts. The average monthly progress was 175 ft. at each heading, or 5.76 ft. per day of 24 hrs. The best year's work was from June 1, 1899, to June 1, 1900, in which time 5,575 ft. were driven from the two headings, the monthly average being 232 ft. per heading. The best month's progress was 527 ft. from two headings; the best week's progress was 143 ft. from two headings; the best month's progress from a single heading (east) was 301 ft. The rock was medium hard granite, very seamy and very wet. Although hard to drill and blast, the granite disintegrated so rapidly that a temporary timber lining was necessary throughout, and it was afterward replaced with concrete.

The work was all done by day labor, no contracts being let, and, in consequence, it cost considerably more than would have been the case had it been built by contract. Three 8-hr. shifts were worked. There were 600 to 800 men employed, and they were not very efficient.

Four columns in a heading carried 5 drills (3 $\frac{1}{4}$ -in. size). From 24 to 28 holes were drilled 12 ft. in the heading, and fired in three rounds by electricity. Including the bench work there were 14 drills used at each end of the tunnel. Rock from the heading and top bench was wheeled in barrows out onto the "jumbo," or "go devil," and dumped through into cars below. A compressed air hoist on the "jumbo" served to lift large rock and to shift the "jumbo" back before firing. Eight electric motor cars were used to haul the muck, etc. One motor hauled 16 to 20 dump cars of 1 cu. yd. each up the 17% grade to the east portal, at 10 miles an hour. The rails were 50-lb. rails laid to a gage of 2 ft.

Large power houses were built at each portal. The east power house contained 1 Ingersoll-Sergeant duplex compressor, 18 x 24

ins.; 1 straight line compressor, 18 x 24 ins.; 1 Rand duplex compressor, 20 x 36 ins.; 1 Buckeye high-speed engine, 12 x 16 ins.; 1 Chandler & Taylor high-speed engine, 12 x 14 ins.; 4 150-hp. boilers; pumps, dynamos, fans and water heaters. Compressed air was delivered through 8-in. mains to the drills, at an initial pressure of 100 lbs.

The tunnel was lined with concrete from end to end, the temporary timber lining being removed. The concrete is nowhere less than 2 ft., and in places it is 2½ ft. thick; spawls and broken stone were packed above the concrete where necessary. To place the concrete without interfering with the muck trains, a platform 500 ft. long was erected, and the cars loaded with concrete were hauled up an incline by a compressed air hoist. The concrete was dumped on the platform and shoveled into the forms. While this was going on another 500-ft. platform was being built in advance. Side walls were built in alternate sections 8 to 12 ft. long, the weight of the timber arches being thus transferred to the walls. The concrete arch centers were made in 12-ft. lengths, of which there were 10 in each end of the tunnel. When the concrete had set, the 12-ft. arch center was lowered with screw jacks onto "dollies," pushed forward 12 ft. and jacked up again. Concrete was mixed, 1 cement, 3 sand and 5 parts rock. About 95,000 bbls. of Portland cement were used in lining the tunnel, an average of 7 bbls. per lin. ft. of tunnel. Work of lining was begun in December, 1899, and finished November, 1900; more than 1,000 ft. of lining having been placed in October, 1900, in the west end, although the general average was about 600 ft. of lining per month from each end. The tunnel was opened for operation Dec. 20, 1900.

Mr. Willard Beahan says that it was a serious mistake to have driven the heading in rock by hand 300 ft. in advance of the bench while waiting for the power plant to arrive, for the long heading overtaxed the transportation so that work on the heading had to be stopped until the bench was brought up. The use of four drill columns he regards as novel, and adds that there was plenty of room in which to work six drills, and that it was not necessary to shift any of the columns in drilling a set of holes.

The actual cost of this tunnel, as originally printed in *Engineering-Contracting*, Dec. 8, 1908, was as follows:

	Per lin. ft.
Engineering	\$ 4.20
Labor excavating tunnel.....	60.60
Explosives	7.40
Power	22.50
Tools (\$137,000)	10.00
Machinery (\$223,000)	16.20
Buildings	3.50
Timber lining	9.40
Concrete lining	43.50
Personal injuries	2.10
Hospital expenses	1.10
Permanent track through tunnel.....	2.80
Total	\$183.40

A comparison of this cost with that of the Stampede Tunnel, through the same mountain range, shows that the Stampede Tunnel was built at less cost, although high contract prices were paid.

Wabash R. R. Tunnels.*—I am indebted to Mr. T. H. Loomis, Div. Eng. P., T. & W. R. R. (Wabash system) for much of the following data kindly furnished by him when I went over the line in 1903 studying the methods and cost of excavation. Eight double-track tunnels were under way, the cross-section of each being as shown in Fig. 1. The material encountered was shale, sandstone, fire clay and occasional seams of coal—characteristic of eastern Ohio and western Pennsylvania. The section above the wall plates (i. e., the longitudinal timbers on top of the posts) requires an ex-

Fig. 1.—Double Track Tunnel.

cavation of 15 cu. yds. per lin. ft. The clear width between wall plates is $34\frac{1}{4}$ ft. The segmental arch timbers are 12×12 ins., lagged with 4-in. plank, the arch ribs being 3 to 4 ft. c. to c. The favorite method of attack, as shown in Fig. 2, was by what I will term the twin-heading method; two 8×8 -ft. headings being driven as shown, and afterward enlarged. The floor of these headings is $12\frac{1}{2}$ ft. above subgrade, thus leaving a $12\frac{1}{2}$ -ft. bench, $A C D E$, to be taken out. One machine drill is operated in each heading (two could be worked) for the drilling is easy. The rivalry between the two drilling gangs in these twin headings appeared to me to be one of the best features of this method of attack. It is certain that no hitherto published data show as low a cost per cubic yard for tunnel work as the data which I secured on this work. The weekly

*Gillette's "Rock Excavation."

progress was not rapid, but, as all the tunnels were comparatively short, there was no necessity of going to great expense in securing rapid progress—a fact that tunnel contractors should bear in mind. Steam drills were used in some of the short tunnels. The following is the actual cost of excavating and timbering the section of a tunnel above the wall plates (16 cu. yds. per lin. ft.), using air drills, for a distance of 100 lin. ft.:

Labor	\$2,597.45
2,000 lbs. 40% dynamite, at 12 cts.	260.00
476 gals. kerosene oil, at 12 cts.	56.40
1,875 gals. gasoline, at 12 cts.	225.00
3,000 bus. coal for compressor, at 9 cts.	270.00
Machine and lubricating oils.	62.50
Blacksmith shop	150.00
41,649 ft. B. M. timber, at \$23.	957.93
Total cost of 100 lin. ft.	\$4,509.28
Cost per lin. ft. above wall plates.	45.09
Cost per cu. yd. including timber.	2.06
Cost per cu. yd., excluding timber.	2.60

The material in this case was sandstone.

On another tunnel the section above the wall plates was excavated by hand at a cost \$40.90 per lin. ft., or \$2.73 per cu. yd., for a distance of 110 ft., the material being hard fire clay in the

Fig. 2.

Fig. 3.

upper half and shale in the lower half of the section excavated, making easier excavation than in the sandstone. The force engaged in hand drilling, by the twin-heading method, was:

	Wages per 10-hr. shift.
1 general foreman	\$ 4
1 foreman	3
1 blacksmith	2
2 carpenters, at \$3.	6
10 miners, at \$2.	20
10 muckers, at \$1.50.	15
1 team	4
Total per shift (10-hr.)	\$55

While these men took out the whole section above the wall plates (16 cu. yds. per lin. ft.) for \$2.73 per cu. yd. for labor and explosives (not including cost of timber), working in shale and fire

clay, they excavated a 7 x 8-ft. heading in sandstone for \$3.75 per cu. yd., distributed as follows:

	Per 10-hr. shift.
Labor on 7 x 8 heading.....	\$18.00
Dynamite	3.84
Repairs90
Light32
Total per shift.....	\$23.06

Each shift excavated 6.2 cu. yds. of this 7 x 8-ft. heading, making the cost \$3.75 per cu. yd., as above stated, equivalent to an advance of 3 ft. per shift.

No night shifts were being worked on the eight tunnels, and the progress per week in shale was 25 ft. when working by hand and excavating 15 cu. yds. per lin. ft.; and 50 ft. a week working with machine drills. In hard sandstone the weekly progress was about 15 ft. by hand and 30 ft. with machine drills, in all cases working only 1 10-hr. shift in the 24-hr. day.

The following is the actual cost of timbering on one job:

	Per M.
Georgia pine f. o. b. cars.....	\$23.60
Hauling 6 miles.....	3.00
Cost of framing.....	5.00
Cost of erecting.....	3.00
Total per 1,000 ft. B. M.....	\$34.60

The carpenters received \$3 per 10-hr. day, and laborers erecting received \$1.50. The cost of framing and erecting, including supervision, was \$8 per M, which was about \$2 more than it should have cost had there been more workers and fewer bosses. Over the rough roads each team hauled about 1,000 ft. B. M. per load and made one trip of 6 miles each way in a day. The cost of "packing" (i. e., placing small stones) above the lagging was 80 cts. per cu. yd.

We now come to what I have said are the lowest records of tunneling cost yet made public:

Tunnel heading in sandstone, double track full section above the wall plate grade (15 cu. yds. per lin. ft.):

	Cu. yd.
Drilling	\$0.60
Explosives40
Mucking85
Total	\$1.85

Tunnel bench in same tunnel:

	Cu. yd.
Drilling	\$0.40
Explosives20
Mucking32
Total	\$0.92

The sandstone was very hard, breaking in large blocks, which have to be drilled and shot before mucking. A steam shovel is used in the bench, and material of heading is carried about 400 ft. and dumped over the breast of bench, whence steam shovel loads it along with bench material.

In another tunnel, in a formation of practically level strata of slate, limestone (thin) and fire clay (a stone hard as limestone to drill, but disintegrating in the air) the cost was as follows:

Heading—full double-track sections—all above wall plates:

	Cu. yd.
Drilling	\$0.48
Explosives30
Mucking80
Total	\$1.58

Bench—same tunnel—full section:

	Cu. yd.
Drilling	\$0.30
Explosives20
Mucking18
Total	\$0.68

In the case of another tunnel in coal formation with a 5-ft. vein of coal running all through on the wall plate grade; steam drills used in rock, and steam coal augers in the coal, with steam shovel for mucking, the costs were as follows:

Headings—per cubic yard—double track:

Labor	\$0.966
Explosives and materials.....	.090
Total	\$1.056

Bench—same tunnel and formation:

	Cu. yd.
Labor	\$0.38
Explosives and materials.....	.04
Total	\$0.42

This last may seem too low, but it was in all probability the cheapest material a tunnel is ever built in, and the organization was so good that it was worked with extreme economy. A core of about 2 cu. yds. per lin. ft. was left in the middle of the heading (between the twin headings) and taken out along with the bench.

Mount Wood and Top Mill Tunnels.—Mr. W. J. Yoder gives the following data: The tunnels (built in 1888-1889) are within the northern city limits of Wheeling, W. Va., and the material penetrated was for the most part shale of the coal measures. The shale disintegrates rapidly upon exposure and must be supported. The block or American system of timbering was used for lining, and was kept never more than 50 ft. back of the face. All drilling was done by hand. A top heading 10 x 84 ft. was driven, and then widened; the bench was taken out in two lifts. The first or cut holes in the heading were drilled so as to blast out a long horizontal wedge

of rock near the roof; these holes being 5 to 6 ft. deep. Then a lower row of 5-ft. lift holes was fired. Finally the bottom of the heading was taken out like a bench by a row of vertical holes and a row of horizontal holes. In all 32 holes were fired in the heading, aggregating 160 lin. ft., and requiring 80 lbs. of 40% Forcite to load them. The effect of the firing was to make an advance of $2\frac{1}{2}$ ft., displacing 25 cu. yds. [The heading gang consisted of 1 foreman, 14 drillers, 12 muckers and 1 nipper.] About 25 lin. ft. of drilling was considered a day's (10 hrs.) work for 3 men. The muck was wheeled in iron barrows to a traveler and dumped down chutes into cars. The heading gang timbered and placed the packing above the arch, two 10-hr. shifts per week being needed for this work, leaving 10 shifts per week for advancing the heading. The timbering is fully described; 660 ft. B. M. of white oak were used per lin. ft. of tunnel. The bench holes were 8 ft. deep, churn drills being used except for the corner holes and for blockholing. The bench force consisted of 1 foreman, 6 drillers, 18 muckers, 2 mule drivers, 3 dump men and 1 nipper. The average haul was about 800 ft.

The maximum monthly progress (working two 10-hr. shifts) in a heading on the Mount Wood Tunnel was 130 lin. ft., the average monthly progress being 84 ft. The maximum monthly progress on the bench was $125\frac{1}{2}$ ft., the average being 97 ft. The average excavation was 10.2 cu. yds. per lin. ft. of heading and enlargement, and 18 cu. yds. per lin. ft. of bench. The total excavation in both tunnels was 49,670 cu. yds., and the excavation in approaches was 25,751 cu. yds.

The number of men employed was 350. The heading men were composed of two-thirds negroes and one-third Austrians. The foremen were Irish. The best drillers were negroes. No work was done Sundays or Saturday nights. The scale of wages (10-hr. shift) was as follows:

HEADING GANG.

1 foreman	\$4.00
14 drillers	1.75
10 muckers	1.50

COST OF LABOR PER LIN. FT. OF TUNNEL.

Labor excavating (heading, \$22.79; bench, \$20.95)	\$43.74
Hauling and dumping.....	5.65
Labor timbering	4.19
Labor framing timber.....	.77
Blacksmithing	1.00
Track repairs21
Labor electric lighting.....	.88
Superintendence and accounts.....	3.00
Total labor	\$58.44
Cost per cu. yd.....	2.06

The above does not include the cost of timber, oil, fuel, wear of tools or explosives. About 1 lb. of 40% Forcits was used per cu. yd. of tunnel excavation, or 28 lbs. per lin. ft. The labor cost was \$2.34 per cu. yd. of heading, and \$1.10 per cu. yd. of bench excavation, making an average of \$1.55 per cu. yd., not including the items of timbering, etc. The labor cost of erecting arch and packing back of it was \$3.19 per lin. ft. of tunnel; or \$7.80 per 1,000 ft. B. M. The labor cost of erecting plumb posts and side lagging and packing same was \$2.33 per lin. ft.; or \$4.27 per 1,000 ft. B. M. The contractors were Paige, Carey & Co., of New York, whose superintendent was Mr. Frank Moran.

Tunnel Driven by Hand on the B. & O.—Mr. J. G. G. Kerry gives description and cost of a short single-track tunnel built in 1891 on the W. Va. & P. R. R., a feeder of the B. & O. system. The tunnel is on a $\frac{3}{4}\%$ grade falling to the south, with a length of 624 ft., in a soft blue clay shale, nearly dry and showing little stratification. This shale disintegrates rapidly on exposure. The width was 23 ft., height from floor to spring line 13 ft.; semi-circular arch of $11\frac{1}{2}$ ft. radius. The area of the heading was 208 sq. ft.; bench, 299 sq. ft.; total, 507 sq. ft. Work was all done by hand. The heading gang consisted of 1 foreman, 8 miners, 6 muckers and 1 nipper. Common laborers were paid \$1.45 and miners \$1.75 per 10-hr. day. Three sets of holes (2 wet and 1 dry) were drilled in the heading; each set consisting of 4 holes about 4 ft. deep; and 24 ft. of holes was considered a good day's work for two miners. Each hole was loaded with 4 to 6 sticks ($\frac{1}{2}$ lb. per stick) of dynamite; and the average advance from a blast was $2\frac{1}{2}$ ft. A scaffold car, or go-devil, was used in handling the muck. It was provided with a derrick and also used for handling timbers, lagging and packing.

The bench gang consisted of 1 foreman, 8 drillers, 10 muckers and 1 nipper. The bench was shot down in 4-ft. holds or lifts, two half-depth blasts being made for each hold. Each blast consisted of four holes, two being center holes, and two nearly vertical under the wall plate. The charge was 10 sticks to an outside hole and 15 sticks to a center hole. Muck was taken out in 1 cu. yd. dump cars in trains of two. Stone flat cars with platforms flush with top of wheels were used for handling large rocks. The bench was kept two wall plate lengths behind the heading, making

the same progress, $2\frac{1}{2}$ ft. per shift. The actual excavation was at the rate of 5 ft. per shift, but the time consumed in pointing down projections, timbering and packing being equal to the time spent in excavation, reduced the average progress to $2\frac{1}{2}$ ft. per shift. The work was done by contract, and it cost the company at contract prices as follows.

11,726 cu. yds. of excavation at \$2.85.....	\$33,419
742 cu. yds. of packing, at \$1.75.....	1,298
256 cu. yds. of fallen rock, at \$1.25.....	320
\$03,000 ft. B. M., at \$30.00.....	9,090
Total 624 lin. ft. of tunnel, at \$70.70.....	\$44,127

The actual cost to the contractor was about \$35,000.

The method of handling and placing the segmental arch timbering is described in detail. The timbering consisted of a 7-segment arch of 12 x 12-in. white oak resting on 12 x 14-in. wall plates on top of the posts. The 16-ft. wall plates were jointed by halving for a foot at each end, so that the forward end always showed the lower half of the joint. The arches were 8 ft. c. to c. The segments of the arches were erected on temporary centers made of 2-in. plank. These centers were erected in two parts and joined at the crown by bolts; a long dog-hook, fastened to the center, was driven into the preceding arch to hold it in place laterally. The arch timbers were wedged solidly against the roof, and the centers withdrawn. The lagging was close laid, all voids being packed with broken sandstone.

Each end of the tunnel was lined with masonry for 50 ft., the centers used in this lining being 25 ft. long and mounted on rollers. During use the centers were supported on wedges, which upon being struck lowered the center enough to clear the rock-faced voussoirs. A hole was left in the crown of the arch-center lagging so that the voussoirs could pass through. Above this a piece or two of the tunnel lagging was removed, and an iron bar placed on the timber arches. A set of blocks was hung from this iron bar, and used to raise the voussoir stone. Gas pipe rollers were put under the stone to roll it to place on the center lagging. The stone was then canted up, and a rope slung around it, six men then sliding it to place.

The contract prices were \$9 per cu. yd. for portal masonry, \$3 for side walls and \$14 for arch sheeting. The cost at contract prices per lin. ft. of that part of the tunnel which was lined (excluding portals, fallen material, etc.), was:

	Per lin. ft.
Excavation, at \$2.85 per cu. yd.....	\$ 53.55
Packing, at \$1.75 per cu. yd.....	2.08
Timbering, at \$30.00 per M.....	14.75
Side walls	20.50
Arch	21.42
Total per lin. ft.....	\$112.30

Cost of the Busk Tunnel.—The Busk Tunnel Ry. Co. built a tunnel 9,395 ft. long on the Colorado Midland R. R. through the Rocky Mts., 11.7 miles S. W. of Leadville. The contract was let to Keefe & Co., and work was begun Sept. 15, 1890. After all but 921 ft. had been driven the work was turned over to the railway company and finished under the direction of their chief engineer, Mr. B. H. Bryant. The tunnel is single track, 15 x 21 ft., with 10.3 cu. yds. per lin. ft. excavation in rock and 13.8 cu. yds. where timbered. The heading was 7 ft. high and the full width of the tunnel. The first 8 holes, 8 ft. deep, were drilled in two rows from the top to bottom, holes being about 2 ft. apart at surface and converging toward the center. The firing of these holes made a V-shaped opening. A second set of holes was drilled parallel to the sides of the tunnel, and when fired the remaining rock was blown into the V-shaped opening. The bench was excavated in the same way. The progress was as follows:

Driving the 2 headings.....	1,118 days
Av. daily progress	8.4 ft.
Av. daily progress, best month.....	10.9 ft.
Best month's (28 days) progress, 1 heading	202.5 ft.

The rock was granite, and in places it disintegrated on exposure, requiring timbering; in other places it was so full of seams as to require timbering; so that 78 per cent of the tunnel was timbered. The contractor was paid for the tunnel as follows:

9,395 ft. of tunnel at \$62.50.....	\$587,103.75
32,575 cu. yds. enlargement for timbering at \$2.50	81,437.50
Cost of timber, 2,725,000 ft. B. M. at \$30.....	81,690.00
Labor timbering at \$12 per M.....	32,576.00

Total 9,395 ft. at \$62.50.....\$782,907.50

The plant at the Ivanhoe end consisted of three 100 hp. boilers, two 20 x 24-in. Ingersoll compressors, one 20 x 24-in. Norwalk compressor, one 10 hp. engine to drive electric light dynamo, one 20 hp. engine to drive a No. 6 Blake blower, 14-in. air pipe, two pumps with 14-in. steam cylinders and 10-in. stroke, six 3½-in. Ingersoll drills (4 in the heading and 2 on the bench), a small traction engine running on a 20-in. gauge track hauling nine 3-yd. dump cars. Coke was used as fuel for the traction engine, so that the smoke did not inconvenience the tunnel workmen.

Cost of a Tunnel Near Peekskill, N. Y.—The following data are given by Mr. Geo. W. Lee, engineer for Sundstrom & Stratton, the contractors who built the double track tunnel described. The tunnel is only 275 ft. long, and is on the line of the New York Central R. R., 2½ miles north of Peekskill. The yardage as shown on the plans was 7,028 cu. yds., but as the rock lay in strata dipping at an angle of 45°, it broke out on the uphill side so as to leave large pockets, in consequence of which the contractor took out 10 per cent more rock than he was paid for. Owing to the seamy condition of the rock, and the proximity of the tunnel to the main line traffic, very light charges of dynamite were used, which

increased the cost and delayed the progress. Rand steam drills, 3-in., were used. A heading 8 x 10 ft. was run and the bench was kept close behind. Rock from the heading was removed in small narrow gage cars; rock from the bench was loaded into standard gage cars by derrick cars. The following was the cost of the tunnel excavation:

Equipment (less present value), supplies and repairs	\$ 2,892.52
Dynamite and exploders.....	1,604.53
Coal	570.80
Oil, waste, etc.....	92.80
Lumber for houses and shops.....	129.88
Miscellaneous	92.10
Labor	22,212.86
Total	\$27,596.54
Average cost per cu. yd. paid for.....	2.93
Average cost per cu. yd. taken out.....	3.54

The tunnel was lined with 1:2:4 concrete; 682 cu. yds. in the bench walls; 932 cu. yds. in the arch; the portal head walls were of 1:3:6 concrete, 324 cu. yds. The cost of the concrete was as follows for the 1,948 cu. yds.:

Cement at \$1.68 per bbl.....	\$ 5,755.50
Sand at 75 cts. per cu. yd.....	662.94
Crushed stone at 80 cts. per cu. yd.....	1,303.20

Lumber.

Mixing platforms and runways.....	\$336.89
Ribs, including hand sawing.....	254.10
Backing boards.....	134.44
Lagging	341.04
Sheathing	268.49
Plates, sills, studs and braces.....	182.75
	<hr/>
	1,497.71
Coal	118.73
Oil	16.12
Hardware, nails, spikes, etc.	224.29
Tools	181.10
Freight on stone, cement, etc.....	2,889.86
Labor, including supt., foreman, etc.....	8,036.31
Total, \$10.72 per cu. yd.....	\$20,885.86

In the approaches to the tunnel and in widening cuts south of the tunnel 45,698 cu. yds. of rock were removed. On account of proximity to traffic, blasting could be done only at limited periods, which made the cost of excavation high. Rock was loaded on flat cars with stiff leg derricks provided with bull wheels. The cost was as follows:

Equipment (less present value, supplies and repairs	\$11,673.60
Dynamite and exploders.....	6,588.82
Coal	2,490.13
Oil, waste, etc.....	370.59
Lumber for buildings.....	634.23
Miscellaneous	373.19
Labor	69,550.86
Total	\$91,681.21
Average cost per cu. yd. paid for.....	2.24
Average cost per cu. yd. taken out.....	2.01

Cost of Tunnelling, Alaska Central Railway.—From data compiled by Mr. G. A. Kyle, and given in a great detail in *Engineering-Contracting*, April 7, 1909, I have prepared the following condensed summary.

The work comprises seven short tunnels located on the Alaska Central Ry., between miles 48 and 52. The work was begun by a contracting firm, but taken over by the railway and finished with company forces. The costs are all high, not only because wages were high and because of location in an inaccessible country, but because work done with company forces is almost invariably more expensive than work done by contract.

Table I shows the length of each tunnel, and the cross-section. It is worthy of note that the "overbreak" averaged 12.1%. The rock was a "hard blocky slate with fractures at right angles to the axis of the tunnels." It broke easily and almost to the theoretical lines of the tunnel, and required no timbering.

The standard cross-section was 14 ft. between side walls and 21 ft. between top of rail and top of tunnel.

Tunnel No. 1 was built by company forces and was begun Jan. 16, 1906. This tunnel was located $1\frac{1}{4}$ miles from the end of completed track. The tunnel was driven entirely from the north end on account of a snow slide on the south end, making it impossible to work on that end, as the work was mostly done in the winter months. The tunnel is 679 ft. long. The first 250 ft. was driven with steam power and drills. The character of material is of a hard rocky slate and is evidently in an ancient slide from the mountains, as the strata were badly broken up, which caused a great amount of overbreak outside of the standard sections, the same being 27 per cent. This tunnel was on a 14° curve and was widened to give a minimum clearance of 18 in. for the maximum length passenger car. The size of the tunnel was 17 ft. wide between timbers, and 21 ft. from top of rail to clearance at top of tunnel. Timber was used for 396 ft. in the north end. The balance was left unlined, but later had to be lined nearly its whole length at an extra high cost, which is not included in the costs as shown below.

The steam plant used in driving the first 250 ft. of the tunnel was one 40 hp. boiler, one 10 hp. boiler; three $3\frac{1}{4}$ -in. Rand drills were used in the heading. The work carried on with the following

TABLE I.—STATISTICS OF TUNNELS, ALASKA CENTRAL RY., SHOWING DIMENSIONS, QUANTITIES, ETC.

No. tunnel.	Length		Totals				Quantities, cubic yards				Per lin. ft.		Per cent. Overbreak in tunnel excavation.

Totals 1,945		3,441	41,648	5,060	46,708	Average yardage 13.074	Per ft. 1.500	13,574	Average yardage 1.500	13,574	Per ft. 13.074	Average 1.500	Average 12.1%

force in each shift of 10 hours (although work was carried on with day and night shifts during a short period):

- 1 foreman.
- 3 machine drillers.
- 3 machine driller helpers.
- 1 muck boss.
- 10 muckers, 2 in head and 8 on bench.
- 1 light tender.
- 1 man on dump.
- 1 man on cars.
- 1 horse.
- 1 engineer.
- 1 fireman.
- 1 blacksmith.

Making 24 men and 1 horse per shift.

The timbering was not kept up with the bench, as the material stood sufficiently well for the men to work, although it was considered dangerous at times.

There were used in blasting 21 or 22 holes in the heading 8 to 10 ft. deep, and the bench was taken out in two lifts generally. The heading was run from 40 to 60 ft. ahead of the bench and scaffolding used to dump the muck from heading directly into the cars from above, two plank runways supported on trestle being used for the purpose.

The steam plant was discontinued on April 14, 1906, as the heat from the escaping steam at the drills made the tunnel too hot for the men to work. The progress with the steam plant was satisfactory with the above exception and seemed to be about the limit that steam can be used economically, viz., 250 ft. from the end of tunnel. The steam was carried from the boilers to the drills in a 2½-in. pipe and the escaping steam was carried from the drills back out of the tunnels in a 2-in. pipe enclosed in a wooden box with the 2½-in. steam pipe to decrease the heat. The progress during the 84 days that the steam plant was used was 250 ft., and the progress made while the air drills were working was about 26 ft. per day, so that about the same progress was made during the steam plant's operation as with the air plant, which was 26.2 ft. This might be accounted for by the fact that from the time that the steam plant was discontinued, April 14, 1906, until April 28, 1906 (14 days), when the air plant was started, there was not much work done in the tunnel excepting to work on the bench, which was considerably behind at that time. From the time the air plant was installed until Sept. 25, 1906, 150 days, the tunnel was worked continuously and was practically finished. The time from Sept. 25 to Oct. 8, the time that the tunnel is shown as completed in Table II, was employed in dressing up and completing the timbering of tunnel. The actual days worked on the tunnel were 334, making the actual progress while work was going on 8 ft. per day. Considerable trouble was had in keeping the force

Lumber for scaffolding and misc'l., 39,383 ft. B. M., at \$12.00.....	0.684	0.037
Hauling above material, 112 tons, at \$1.60.....	0.256	0.014

Total materials.....\$ 2.620 \$0.142

Total making roads and trails.....\$ 1.717 \$0.093

Total excavation.....\$ 96.083

Total timber lining (see Table IV).....\$ 11.205 \$0.605

Total cost of tunnel.....\$138.453 \$7.477

Summary.

	Per lin. ft.	Per cu. yd.
Compressor and steam plant.....	\$ 3.943	\$0.212
Fuel compressor and steam plant.....	5.628	0.304
Engineers and firemen compressor plant.....	3.136	0.169

Total compressor plant.....\$ 12.707 \$0.685

Pipe line connections, etc.....2.350 \$1.26

Grand total compressor plant.....\$ 15.057 \$0.811

Lighting tunnel.....4.303 0.232

Blacksmithing 6.369 | 0.344 |

Labor on excavation.....79.401 4.288

Explosives 12.345 | 0.668 |

Material used in excavation for scaffolding, etc.... 2.620 | 0.142 |

Roads and trails.....1.717 0.093

Timber lining.....11.205 0.605

Engineering and superintendence.....5.436 0.294

Total cost of tunnel.....\$138.453 \$7.477

There were 63.3 lbs. of dynamite used per lin. ft. of tunnel, or 3.57 lbs. per cu. yd.

There were nearly 30 lin. ft. of hole drilled per lin. ft. of tunnel, or 1.6 lin. ft. of drill hole per cu. yd. The extravagantly

expensive cost of this drilling is seen when reduced to the cost per lin. ft. of drill hole:

	Per ft. of hole.
Total compressor plant charges (\$15.057 per lin. ft. of tunnel).....	\$0.51
Wages of drillers and helpers.....	0.23
Total per ft. of drill hole.....	\$0.74

The plant used on this tunnel was as follows:

1 40 hp. firebox, water bottom boiler with stack injector and feed pump.

1 12x12x14 inch Franklin straight line air compressor, steam driven, capacity 350 cu. ft. of air per minute.

1 30-inch by 10 ft. air receiver.

750 ft. 4-inch gas pipe.

400 ft. 2½-inch gas pipe.

300 ft. 1-inch gas pipe.

450 ft. 1-inch armored rubber air hose.

150 ft. 2-inch armored rubber air hose.

3 3¼ Rand drills.

4 3½ Rand drills.

2 2¾ Rand drills.

5 tripods.

3 columns.

5 arms.

1,000 lbs. X steel.

Blacksmith outfit.

Pipe tools.

Pipe fittings.

Repair parts for drills.

TABLE IV—COST OF TIMBER LINING.

	Total	Per lin. ft.
Company force, 148 ft. tunnel lining.		
80 cords wood, at \$3.32 per cord.....	\$ 266.57
80 cords wood, at \$3.00 per cord.....	240.00
Total cord wood.....	\$ 506.57
5,400 ft. B. M. timber, at \$22.22....	1,199.88
566 lbs. iron, at 5c.....	28.33
6,400 ft. B. M. timber, at \$12.....	648.00
Total for timber.....	\$1,876.21
Total for 148 ft. lin. lining.. . . .	\$2,382.78	\$16.010

Contract for 248 lin. ft.		
952 lbs. iron, at 5c.....	47.60	\$ 0.192
Lumber on hand.....	667.76	2.693
106,530 ft. B. M. timber, at \$12, at end of track..	1,278.36	5.154
106,550 ft. B. M. timber, at \$20.....	2,130.60	8.591
Timber framed on hand.....	84.00	0.339
Total timber for 248 ft. tunnel.....	\$4,208.32	\$16.969
99.74 cords wood, at \$4, labor.....	398.96
90.56 cords wood, at \$3, labor.....	271.68
190.30 cords wood, at \$3, material end track....	570.90
Total cords wood back filling.....	\$1,241.54	\$ 5.006
Cost of 248 lin. ft. lining.....	\$5,449.86	\$21.975
Total for 396 lin. ft. tunnel lining.....	\$7,832.64	\$19.782
Total for 699 lin. ft. tunnel lining.....	\$7,832.64	\$11.205

The wage scale was as follows:

Position.	Per month.	Per day.
Superintendent	\$300	...
Walking boss.....	* 175	...
Shift bosses.....	...	†\$5.00
Muck bosses.....	...	† 4.00
Machine drillers.....	...	† 4.00
Machine helpers.....	...	† 3.00
Carpenters	† 4.00
Blacksmiths	† 4.50
Powder thrower.....	...	† 3.50
Machinist	† 125	...
Engineers	† 125	...
Firemen	† 3.00
Muckers	†2.75 to 3.00
Carmen	†2.75 to 3.00
Other general labor.....	...	† 2.75

*And board. †Paid their own board at \$5 per week.

The prices of explosives were as follows:

	Per lb.
Dynamite, 70 per cent.....	\$0.186
Dynamite, 60 per cent.....	0.170
Dynamite, 40 per cent.....	0.160
Black powder.....	.075
Champion powder.....	.110
Vigorite120
Trimiff110
	per 100.
Caps	\$0.90
	Per
	100 ft.
Fuse	\$0.75
Electric exploders, 4' to 14' leads, average all lengths, 10 ft..	5.00

Tunnels Nos. 2, 3, 6 and 7.—The character of rock in all these tunnels was practically the same, being a hard blocky slate with fractures at right angles to the axis of tunnels. The rock drilled and broke easily and almost to the theoretical lines of the tunnel, and did not require any timbering, for the present at least.

The standard cross section was 14 ft. wide between side walls and 21 ft. between top of rails and clearance at top of tunnel.

The lighting was with torches and Wells standard lights, one of the latter in each face of tunnel, and gave good satisfaction, the electric lighting plant that was bought for the purpose not being used.

	Lbs.
Explosives used in these tunnels were.....	\$0.394
Per lineal foot of tunnel.....	44.7
Per cubic yard in tunnel.....	3 57
Per lineal foot of hole drilled in tunnel.....	1.46

The work was carried on in the same manner as tunnel No. 1, viz.: using 21 holes in the heading, 8 ft. deep, and the bench taken out generally in two lifts, the muck taken from the headings on wheelbarrows by two men and wheeled on planks supported by trestles and dumped directly into the cars from the wheelbarrows. The work was carried on in shifts of 10 hours each, part of the time day and night, with the following force in each shift, viz.:

- 1 horse.
- 1 foreman.
- 1 muck boss.
- 3 machine drillers.
- 3 machine driller helpers.
- 1 light tender.
- 8 muckers, 2 in heading, 6 on bench.
- 1 dump man.
- 1 car man.
- 1 blacksmith.
- 1 engineer.
- 1 fireman.

Making 23 men and 1 horse in all per shift.

When the company took these tunnels over from contractors, Mr. Martin Moran, who is an experienced tunnel man, was hired as general superintendent to look after the work.

There was also trouble in keeping men on these tunnels on account of scarcity of labor at that time, and a system of paying a bonus of so much per foot to each man connected with the work after a certain number of feet per day was driven, was put into effect, which is shown in Table II.

The actual work of driving tunnel No. 2 by air was begun Feb. 20, 1906, and finished May 12, 1906, requiring 81 days to complete the remaining 280 ft. or an average of 3.46 ft. per day.

Tunnel No. 3 was driven from both ends; from the south end 529 ft. and from the north end 426 ft. by air drills; 75 ft. of the south end was driven by hand, and the remaining 454 ft. by air drills. Work on the south end began with the air drills on Feb. 20, 1906, and finished July 11, 1906. The north end was begun Feb. 28 and finished July 11, 1906, an average of 3.20 lin. ft. per day on the south end and the same on the north end.

Tunnel No. 6 was begun with air June 18, 1906, and finished Oct. 15, 1906, requiring 120 days to finish at an average per day of 1.61 lin. ft. The slow progress of this tunnel is evidently on account of the lack of power to run three headings at a time, as they were working in tunnel No. 7 at both ends at the same time, and it was impossible to carry all the headings on full force at once.

Tunnel No. 7 was driven from both ends at once time, but the exact data are not available to segregate the number of feet driven on each end. This tunnel was begun May 24, 1906, and finished Nov. 4, 1906, requiring 145 days to complete at an average of 4 ft. per day.

See Table II for other data. Wages and prices of materials were the same as for tunnel No. 1, above given.

These four tunnels (Nos. 2, 3, 6 and 7) had a total length of 2,024 ft., involving the excavation of 25,257 cu. yds. of rock. There were 31.5 ft. of drill hole per lin. ft. of tunnel, or 2.43 ft. of drill hole per cu. yd.

The itemized cost of the work on these four tunnels averaged as given in Table V.

TABLE V.—AVERAGE COST OF 4 TUNNELS.

	Per lin. ft.	Per cu. yd.
<i>Compressor Plant:</i>		
Dep. compressor plant, interest, etc. (30% first cost)	\$ 2.402	\$0.192

Superintendence	289.60	1.28	.10
Total cost	\$17,822.60	\$58.62	\$4.78

It will be seen that the tunnels driven by company forces cost 50% more than the tunnels driven by contract.

Cost of the New Raton Tunnel.*—Mr. Joseph Weidel, Asst. Engr., A. T. & S. F. Ry., gives the following:

**Engineering-Contracting*, May 3, 1909.

During the latter seventies of the past century, when the Santa Fe Railway was built westward and southward through Colorado and New Mexico, a tunnel was found to be necessary in crossing the divide of the Raton Range, a spur of mountains projecting eastward from the Taos Range in southern Colorado. This tunnel was built during the years of 1878 and 1879, and while it was under construction a switch back was used in crossing the range. Its length is 2,037 ft., and it is on an ascending grade of 2% from the east; the summit being at the west portal. The grades approaching the tunnel, from either end, are 184.8 ft. per mile. The tunnel is 18½ ft. high above top of rail and has a clear width of 14 ft. About 50% of the tunnel is lined with timbers.

This original tunnel had been in constant use for about 29 years when the increase in traffic, size of rolling stock, and loads, and the necessity of extensive repairs forced the company to build a new tunnel. The new tunnel occupies a site adjacent to the old one and at the east portal the two are only 40 ft. apart, center to center. At the east portal the subgrade of the new tunnel is about 12 ft. lower than the subgrade of the old tunnel. The new tunnel is on an ascending grade of 0.50% from the east; the summit being at the west portal.

The new tunnel is 2,786 ft. long, 17 ft. wide at spring line, and 34 ft. high above top of rail and is lined throughout with a concrete wall of an average thickness of 24 ins. There are two shafts approximately 6 x 10 ft. in the clear. One of these shafts is 686 ft. from the east portal and the other 1,100 ft. from the west portal.

The contract for the construction of the tunnel was awarded to The Lantry Contracting Co., a Kansas corporation, organized for this particular purpose. The papers were signed on April 5, 1907, and stipulated that the tunnel was to be completed, ready for track laying, by March 1, 1908. There was a penalty and premium clause in the contract of \$100 per day for every day's variation from the stipulated time of completion.

In what follows, it must be borne in mind that the contractor had not hitherto been in the business of tunnel building and he consequently found himself without a suitable working plant or organization at the time the contract was signed.

Mr. Charles E. Higbee, of Denver, Colo., was engaged as Superintendent of Tunnel Excavation and Mr. S. A. Maley, of Kansas City, Mo., was engaged as Superintendent of Concrete Work. Both of these gentlemen had had wide experience in their respective fields, and it was under their direction that the work was successfully completed.

A central power plant was installed near the west end of the tunnel. The principal items of this central plant were, one battery of two horizontal tubular boilers of 160 hp. and 80 hp., respectively; one Sullivan Straight Line Air Compressor W. B. 3, 20 x 22-in. cylinder; one 90-hp. Armington & Sims steam engine for driving the generators; two 25-kilowatt Bipolar Edison Generators of 125 volts; together with pumps, tanks, steam and water pipes

and such other appliances as are needed in an up-to-date power house.

A secondary steam plant was located on top of the mountain for the purpose of supplying power for operating the hoists at the shafts. A 100-hp. boiler was installed and the steam was carried in pipes laid on the surface of the ground, from the boiler to the hoist, for a distance of 500 ft. each way.

From the central power plant at Lynn a 4-in. air line was laid along the surface of the ground, over the top of the mountain, to the Wootton portal. At the Lynn portal, as well as each of the shafts, 2-in. tees were inserted, from whence the air was carried down into the headings and shafts by 2-in. pipes.

The drilling machinery consisted of 10 Sullivan piston and 10 Jeffrey rotary power drills. For ventilating, 2 No. 4½ Baker's rotary blowers were secured. These were operated by 2 7½-hp. motors of 230 volts and 28½ amperes. This outfit was moved from place to place as needed. The cages in the shafts were operated by hoisting engines, using either compressed air or steam.

For excavating the bench, a No. 20 Marion steam shovel was used. This shovel was operated by compressed air from the central power plant. Three dinky engines kept the shovel supplied with cars. Ten 3-cu. yd. dump cars were needed to supply the shovel, 5 in a train.

The rock crushing and concrete mixing plant consisted of 1 Ajax boiler, an engine mounted on wheels, 1 Simmons No. 10 rock crusher, 1 ½-cu. yd. concrete mixer of the Ransome type, 10 1½-cu. yd. dump cars and an incline for hoisting the loaded cars from the tunnel grade onto the working platform at the spring line.

There was also constructed an electric light and power line over the mountain for supplying light and power to the camps and tunnel. A telephone system was also installed.

The grading outfit was of the usual kind.

Owing to the lack of water on top of the mountain the company shipped in four tank cars full every 24 hrs., approximately 40,000 gals. being required for all purposes each day.

On April 25, 1907, ground was broken for the power plant at Lynn. While the camp and power plant were in course of construction work on excavating the approaches at Wootton and Lynn was in progress. On April 3 work was begun excavating the shafts. The drilling was done by hand and the excavated material was hoisted by animal power. These shafts were dug about 8 x 12 ft. in the clear and were 109 and 115 ft. deep, respectively, measured from the crown of arch in tunnel. The material penetrated was soft sandstone, hard shale and some coal.

By May 9, when the power plant was ready for service, the excavation of the shafts had been practically completed, all of the work having been done by hand and animal power. For the benefit of those who may have occasion to construct shafts under similar

conditions, I submit the following table, which shows the cost of excavating Shaft No. 1:

Foreman, at \$4.50.....	\$ 375.25
Shaft men, at \$3.....	1,792.50
Nippers, at \$2.....	32.00
Timber men, at \$3.50.....	56.00
Teams, at \$2.50.....	132.50
Teamsters, at \$2.....	96.00
327 cu. yds. excavation, at.....	\$2,484.25

The cost per cubic yard of excavation was, then, as follows:

	Per cu. yd.
Labor	\$7.60
Explosives75
Supervision65
Total	\$9.00

It may be stated that this includes the placing of approximately 20,000 ft. B. M. of timber lining.

On May 9 the actual work of tunnel excavation was begun by shooting the first round of holes in heading No. 6 at the Lynn portal. On May 24 heading No. 5 was started and on May 28 heading No. 1

a

Fig. 4.—Cross-Sections of Tunnel.

was started. On July 9 headings No. 5 and No. 6 met at Station 7 + 12, Lynn end, and on same date headings Nos. 2, 3 and 4 were started. Headings Nos. 1 and 2 met on Aug. 8 at Station 8 + 10, Wootton end. Headings Nos. 3 and 4 met on Sept. 8 at Station 2 + 00, Wootton end, thus completing a hole through the mountain 2,786 ft. long in 122 days from time of beginning.

In taking out the headings it was found that from 12 to 18 holes were necessary to cover the face in a satisfactory manner. The center set of holes was pointed so as to remove a wedge of rock; other holes were then pointed straight ahead. Those at the sides, top and bottom were pointed slightly outward. The average depth of these holes was 8 ft and the diameter $2\frac{1}{2}$ in. Sullivan piston and Jeffrey rotary drills, the former mounted on tripods and columns and the latter on the usual frames, both operated by compressed air at 90 lbs. pressure, were used.

As soon as the drilling was finished the holes were cleaned by blowing compressed air into them. They were then charged with dynamite, which was exploded by fuse. Fuses instead of electric exploders were used because of the former permit of timing each shot in such a way as to give the best results from the explosives used. For instance, the central set of holes is fired first, removing a wedge so that the succeeding shots will have two free faces toward which they can break the rock. The "muckers" at the bottom are fired last. Their function is to throw back the debris so that the drillers will be delayed as little as possible before they can proceed with the next set of holes.

The shots were generally fired just before meal time. Immediately after they had been fired, compressed air was permitted to escape into the headings and the ventilating fans were started. It was thus possible to clear the headings of gases so that they could be entered after the meal hour without loss of time. Before firing the shots, sheets of boiler iron were spread on the ground just in front of the holes to facilitate the handling of debris after blasting.

When the workmen returned from their meals the headings had usually been cleared of gases and fumes and the drillers and their helpers would enter and proceed to shovel back any rock that was found to obstruct the working front. As soon as this was done, they proceeded to drill a new set of holes for the next blast. The debris was loaded by from 6 to 10 laborers onto cars of $1\frac{1}{2}$ cu. yds. and $\frac{3}{4}$ cu. yd. capacity. The former were used in the headings No. 1 and No. 6, while the latter were used in headings Nos. 2, 3, 4 and 5. The former were pulled by animal power to the portals and the latter were propelled by man power to the shafts. From the portals the $1\frac{1}{2}$ cu. yd. cars ran by gravity to the waste bank, the empties being brought back by horses or mules. The smaller cars at the shafts were raised to the surface by hoisting engines operating cages.

The following is a statement of the cost of excavating heading No. 4:

	Rate.	Total.
Machine foremen	\$4.50	\$ 495.00
Machine men	4.00	1,196.00
Machine helpers	2.50	1,046.00
Nippers	2.50	507.50
Muck foremen	3.50	387.00
Laborers	3.25	2,975.50
Teams	2.50	315.00
2,897 cu. yds. material excavated...		\$6,922.00

The cost per cubic yard for excavation was as follows:

	Per cu. yd.
Field labor	\$2.39
Labor operating power plant.....	0.31
Labor in camp and supervision.....	9.88
Powder, fuse and caps.....	0.55
Coal	0.80
Depreciation	0.66
Total	\$6.08

A summary of the total and unit costs of all 6 headings is given below:

No.	Length.		Total cost.	Cost. per cu. yd.
	Ft.	Cu. yds.		
1	476	3,165.....	\$17,534.10	\$5.54
2	210	1,028.....	5,550.58	5.41
3	400	1,845.....	8,320.96	4.51
4	600	2,334.....	12,233.78	5.27
5	312	1,584.....	9,274.52	5.86
6	788	2,897.....	14,710.76	5.08

The material penetrated in heading No. 1 was soft sandstone, while the other headings were mixed sandstone, coal and shale. The most rapid progress was made in heading No. 6, where there was no timber lining to contend with. The average daily progress in this heading was 12½ ft., while for the last nine days the daily average was 17 ft. This, of course, means per 24 hrs. About 55% of the headings were taken out through the shafts.

In moving the bench, holes were drilled vertically about 7 ft. apart. These were shot as in open cut work. The muck was loaded by a No. 20 Marion steam shovel, operated by compressed air. Ten 3-cu. yd. dump cars were used, five in a train. These trains were operated by three dinky engines, one switching at the shovel, one taking the excavated material to the waste dump and one in reserve.

Following is the steam shovel monthly progress.

July	50 ft.	October	355 ft.
August	420 ft.	November	565 ft.
September	540 ft.	December	500 ft.

About 88% of the bench was removed by steam shovel and 12% by hand. If we take into account the entire tunnel excavation, 25% came out through the shafts and 75% through the portals.

The steam shovel began work on July 22 and finished on Dec. 23, a period of 148 days. Below follows a table showing the cost of removing 29,417 cu. yds. of bench excavation by steam shovel:

	PAID	TOTAL
Foremen	\$4.50	\$ 1,300.50
Steam shovel engineer.....	6.50	1,839.50
Crane men	3.50	897.00
Dinky engineers	3.50	1,791.00
Machine men	4.00	3,604.00
Machine helpers	3.50	3,244.50
Pit men	3.00	5,792.00
Laborers	2.00	6,151.75
29,417 cu. yds.....		\$24,621.25

The cost per cubic yard was as follows:

	Per cu. yd.
Field labor	\$0.88
Labor operating power plant.....	0.09
Camp labor and supervision.....	0.26
Powder, fuse and caps.....	0.17
Coal	0.09
Depreciation ..	0.19
Total	\$1.68

In excavating the tunnel no unusual difficulties were encountered. There was very little water to contend with and the material penetrated was sandstone, shale and coal. About two-thirds of the entire tunnel had to be temporarily lined with timbers. The work was done in the following manner:

As soon as the headings had advanced sufficiently a gang of drillers was set to work enlarging the section to the full semi-circle required. Sills consisting of 12 x 12-in. timbers were bedded at the spring line on each side of tunnel, so that the outer face was a uniform distance of 5 or 12 ins. from the face of the concrete. Engineers gave grade and centers for these and in placing them they were set 4 ins. higher than the theoretical requirements. This was done to allow for subsequent settlement during the excavation of the bench. As soon as the sills were bedded to proper grade, the segments, six in number, were placed. These were made of 10 x 12-in. pieces, or an equivalent section of 3 x 12-in. or 4 x 12-in., was built up. The sill, by the way, was also built up of 3 x 12 or 4 x 12-in. pieces, set edgewise. The segments were spaced 3 ft. on centers. Over the segments 3-in. lagging was placed, this having previously been cut into 3-ft. lengths by means of a circular saw. As soon as the lagging was placed, the void spaces between the lagging and the roof of the excavation were packed solid with stones of various sizes. As fast as the bench was excavated by the steam shovel, it was of course necessary to support the sills at spring line. In this case ordinary piles about 12 ins. in diameter were used. These were spaced variously from 3 to 6 ft. apart, according to the load to be supported. Where the loads were light it was found that short stulls from 4 to 6 ft. long made of 3 x 8-in. stuff answered very well for supporting the roof timbering. In such cases, horizontal struts had to be inserted to prevent the timbers from kicking in at spring line.

The work of enlarging the section, the placing of timbers and the back filling was done by the same set of men. Owing to this circumstance the records of cost data are somewhat less satisfactory in this case than in other portions of the work. Of these three items the records for the cost of enlarging the tunnel section are quite reliable. By subtracting this cost from the total cost of performing the different classes of work, we have an amount which represents the cost of labor placing the timbers and the cost of labor placing the backfilling.

The cost of enlarging the tunnel section was \$2.55 per cu. yd. After repeated trials the cost of placing the timbers was ascertained to be \$15.55 per M ft. B. M. By subtracting these two, the cost of enlarging the section and the placing of the timbers, the remainder was assumed to represent the cost of back filling. By this process of reasoning it was found that the cost of placing the backfilling was \$1.50 per cu. yd. In the abstract such reasoning may be correct, but practically the writer has little faith in the results. Summing up, then, it may be assumed that the cost of enlarging the section is correctly represented by \$2.55 per cu. yd., that the cost of placing the timbers lies between \$12 and \$18 per M

ft. B. M. and that the cost of placing the backfilling was not ascertained.

While the steam shovel was taking out the bench a gang of men was excavating for the footing course of the concrete walls. As soon as portions of these trenches were excavated another gang placed the concrete in the foundation. The mixing was done by hand on sheets of boiler iron placed in front of the trenches. These were moved from place to place as required. However, before any concrete was placed, carpenters erected a sufficient amount of forms to define the neat line of concrete at grade. For setting these forms engineers gave the grade and center points and after the concrete was once placed to this line no further instrumental work was required. All of the foundation concrete, up to the grade line of the tunnel, was placed in the manner indicated above.

For the real work of lining the tunnel the contractor installed a rock crushing and concrete mixing plant in the approach at Lynn, about 200 ft. from the portal. The rock was quarried from the adjacent hill, within 100 ft. of the crusher, which was a No. 10 Simmons. The mixer was of the Ransome type, mixing $\frac{1}{2}$ cu. yd. per charge. The crusher was at the top of the approach slope, about 20 ft. above grade. A bin, divided into three compartments, was placed above and to one side of the track in the approach. In the bottom of the compartments were chutes discharging into a measuring hopper. Immediately below the hopper was the mixer and below the mixer and a little to one side stood the cars that received the mixed concrete. The rock was carried from the crusher into the bin by a small chain elevator and the sand was handled in a similar manner. The cement was carried to the bin in sacks. Water was supplied by a 3-in. pipe discharging into the mixer, the amount being controlled by a boy operating a valve. One man operated the measuring apparatus and one attended the mixer.

It will be seen that the entire process of handling the material from the crusher until the concrete reached the cars was mechanical and from the bin to the cars gravity did the work.

The crusher was operated by a stationary engine and the mixer and elevators by independent electric motors. The cars were handled by dinky engines. The sand was shipped from La Junta. The crushing and mixing plant was a complete success from every point of view.

Originally it was the contractor's intention to place all of the concrete lining, above foundation line, off a movable platform at spring line. With this idea in view a standard flat car was secured from the railway company and by means of framework placed upon this car a platform 17 ft. wide and 50 ft. long was supported at the elevation of spring line. This car was carried on a track laid in the center of the tunnel. In order to elevate the concrete cars as they arrived from the mixing plant to spring line, an inclined plane (Fig. 5) with a narrow gauge track and mounted on wheels was coupled onto the platform mentioned above. On the flat car was mounted a hoisting engine operated by compressed air. The cars were pushed to the bottom of the incline by dinky engines,

where a cable was hooked onto them and they were then hoisted to the top of platform by means of the holsting engine. Once on top the concrete was dumped onto the platform and cars returned by gravity to tunnel grade. The concrete was then shoveled into the forms and the idea was that the arch ring would also be turned

Fig. 5.—Method of Handling Concrete for Lining.

at once before advancing the incline and platform to a new position. It was found to be impossible to turn the ring fast enough without delaying the placing of concrete in bench walls. A feature of the forms was to use two 40-lb. bent rails, one on each side and meeting at soffit line, as ribs for supporting lagging for concrete. It is evident that a movable platform will not permit of bracing these

ribs crosswise of the tunnel axis. Owing to this circumstance these ribs lacked stiffness and bulged out considerably when concrete was shoveled into the forms. The long and heavy bent rails were also very difficult to handle. Owing to these drawbacks, this method of placing the concrete was abandoned.

During the short time that the above method of placing the concrete was in vogue it became evident that, in order that work might be carried on without interruption, a platform of considerable length was necessary. It was decided, therefore, to erect a fixed platform at spring line 17 ft. wide and 500 ft. long. Instead of the bent rails for ribs, 6 x 8-in. vertical studding spaced 4 ft. on centers was used. These pieces extended from grade line to spring line and were cross braced about 10 ft. above grade line. On top of these uprights were placed 6 x 10-in. caps, which acted as beams for carrying the loose 2-in. platform floor. The lagging was placed directly behind the vertical studs, to which it was loosely nailed. The old movable platform, mounted on a flat car, and the inclined plane, were then run up to the 500-ft. fixed platform and the concrete was hoisted as before.

While the carpenters were placing the fixed platform, the mixed concrete was brought in and dumped onto sheets of boiler iron at grade line and from there was shoveled into the forms to a height of about 6 ft. above grade. By the time that this height was reached the platform was ready and all concrete above this 6-ft. line was then placed from the fixed platform at spring line. In the center of this platform, for its full length, was a track connecting with the track on the incline. The cars, after they had been hoisted to the platform, were pushed by men to different places and dumped. The cars were then pushed back to the incline and lowered to tunnel grade by gravity, controlled by hoisting engine on movable platform. The concrete was shoveled into the forms until the spring line was reached. As soon as a portion of the bench walls had reached spring line a gang of men erected rail ribs of a 40-lb. section bent into the form of a semi-circle to receive the lagging for turning the arch ring. These rails were generally made in two pieces and were spaced 4 ft. on centers. The lagging was 2-in. stuff and was placed as fast as the placing of concrete required it. The distance from spring line to soffit line is $8\frac{1}{2}$ ft. The placing of concrete in the arch ring for the first 6 ft., did not differ materially from the method of placing it in bench walls, only a little more tamping was necessary to fill the voids. After a point was reached where it was too high to cast in the concrete from the platform at spring line, a small movable platform on wheels, about 8 x 10 ft. and 4 ft. high, was pushed under the arch and the concrete was shoveled from platform at spring line onto this smaller platform and from there into arch ring until only a 3-ft gap remained to be

This was an awkward job and required the closest attention on the part of the foreman to prevent the men from slighting their work. The concrete had to be shoveled in endwise and to facilitate this the length of the lagging for the last 3 ft. of arch ring was cut

down to 3-ft. lengths. The concrete for this was made dryer to prevent it from sloughing back when the tamper was withdrawn.

The temporary timber lining was imbedded in the concrete and had been so placed that at least 6 ins. of concrete was in front of all ribs and sills. In places where the timber had settled or swung out of line, the timbers had settled to such an extent as to weaken the arch, the wooden ribs were replaced by bent rails.

The progress made in lining the tunnel by months was as follows:

	Cu. yds.
October	326
November	1,000
December	985
January	1,986
February	4,173
March	2,981
April	1,026

Besides the tunnel lining proper, the two shafts were also lined with concrete. This was done by force account. At the Wootton end a reinforced concrete portal wall was built and at the Lynn end one of plain concrete was constructed.

The cost per cubic yard of placing concrete, exclusive of the cost of cement, was found from records kept by the assistant engineer to be as follows:

	Per cu. yd.
Forms and platforms, labor.....	\$0.63
Forms and platforms, lumber.....	0.54
Crushing and quarrying rock.....	0.89
Cost of sand (no freight).....	0.18
Cost of handling sand at tunnel.....	0.18
Cost of handling cement at tunnel.....	0.17
Cost of housing cement at tunnel.....	0.04
Mixing and transporting concrete.....	0.41
Placing concrete into forms.....	0.81
Removing forms and pointing.....	0.22
Supervision and camp labor.....	0.66
Labor operating power house.....	0.20
Coal	0.34
Depreciation of plant.....	0.65
Nails, oil and candles.....	0.03
Rental on rails and ties.....	0.03
Total	\$6.08

The lining of the tunnel proper was completed on April 15, while the whole contract was finally completed on June 20, 1908, 444 days after ground was broken.

The cost of the contractor's plant in this case was estimated at \$55,000. The outfit was purchased especially for this contract and at the conclusion of the work the contractor offered to sell the plant at 60 cts. on the dollar. This fact accounts for the heavy depreciation charge in the unit costs.

The unit costs given in this article are based upon records kept by the writer as assistant engineer in charge for the railway company. A man was employed to keep this record, who had no other duties to perform, and the results were tabulated every day. From facts known to the writer it is his belief that 10% should be added to these figures to arrive at the actual total cost.

The work was planned and carried on under the direction of Chief Engineer C. A. Morse, of Topeka, Kan., and Engineer F. M. Bisbee of La Junta, Colo. The field force consisted of Assistant Engineer

Fig. 6—Cross-Section of Tunnel.

Fig. 7.—Longitudinal Section of Tunnel.

Jon. Weidel with an instrument party and, latterly, during the construction of concrete work, one day and one night Inspector.

Cost of Driving a Tunnel in Earth.*—During the past decade a

**Engineering-Contracting*, July 1, 1908.

large number of descriptions have been written of driving tunnels through rock, but only a few tunnels excavated through soft materials have been described in engineering literature, and then only those in which special methods were used, or unusual difficulties encountered. The tunnel described in this article could not be classed as unusual in any respect, nor were any novel methods used on the work, but inasmuch as we are able to give the itemized cost of the tunnel, it may prove of interest.

The tunnel was on the line of one of the large western roads, on the outskirts of a town, crossing under some of the streets, but without many houses in that neighborhood. The length of this single-track tunnel was 2,360 ft. It was lined with timber as shown in Figs. 6 and 7. The cross-section was designed to have ultimately a lining of concrete. There were about 15 cu. yds. of excavation to the running foot figured for the cross-section as designed, which meant a total excavation of 35,385 cu. yds., not including any slips or falls.

The material excavated was mostly a glacial deposit or till, there being at one end some cemented gravel that had to be blasted while the other end was mostly sand. Temporary timbers had to be used and some trouble was experienced with the earth slipping, as the method of putting in the timber roof shows.

The work was done by company's forces and the following wages were paid, the working day being 10 hrs.

Resident engineer.....	\$250.00 per mo.
Assistant engineer.....	125.00 per mo.
Transitman	85.00 per mo.
Draftsman	75.00 per mo.
Rodman	50.00 per mo.
Chainman	40.00 per mo.
Axeman	2.25 per day
Extra chainman.....	2.25 per day
Superintendent	225.00 per mo.
Accountant	75.00 per mo.
Purchasing agent.....	70.00 per mo.
Material clerk.....	70.00 per mo.
Clerk	40.00 per mo.
Cook	45.00 per mo.
Heading foremen.....	5.00 per day
Bench foremen.....	4.00 per day
Track foremen.....	2.50 per day
Foremen	2.50 per day
Miners	3.00 per day
Muckers	2.00 per day
Nippers	2.00 per day
Team and driver.....	5.00 per day
Horse and driver.....	3.00 per day
Rail drillers.....	2.50 per day
Trackmen	2.00 per day
Dumpmen	2.00 per day
Carpenter foreman.....	3.50 per day
Carpenters	2.50 per day
Blacksmith	3.00 per day
Helper	2.00 per day
Timber inspector.....	2.50 per day
Timekeeper	2.25 per day
Mortormen	2.75 per day

The following men were used at times and paid the following wages:

Electrician	\$100.00 per mo.
Linemen	\$2.50 to 2.75 per day
Carshop foreman.....	3.00 per day
Carshop carpenter.....	2.50 per day
Mechanists	\$2.50 to 3.50 per day
Masons	4.00 per day

Engineering and Superintendence.—Under this head is given the cost of superintendence and the engineering work. The superintendence was a cost that would have come under the contractor's item of general expense, if the work had been done by contract. The two items of engineering and superintendence were kept together, but the superintendence was more costly than the engineering, as the resident engineer gave only part of his time to the tunnel work, and even the assistant engineer's salary was not charged in full against the tunnel. The items going to make up this charge were:

Payroll	\$4,582.67
Supplies and incidentals.....	174.81
Board	662.99
Telephone for office.....	21.30
Light for office.....	61.16

Engineering and superintendence.....\$5,544.93

This gives a cost of 16 cts. per cu. yd. of excavation and a cost of \$2.35 per lineal ft. of completed tunnel.

Camp and Offices.—A camp was built near the tunnel site for the men to live in, and an office was also established for the superintendent and the engineers. A temporary depot was built, and a freight house to store supplies. Electric lights were used in some of these buildings, and water was also placed in some, being procured from the town.

The total cost of camp was \$3,177.93, and, as some of the buildings were sold and the depot was given to the operating department of the road, a credit of \$492 was made to this account, making the net cost of the camp \$2,685.93. This means a cost per cu. yd. of excavation of 8 cts., and a cost per lin. ft. of tunnel of \$1.14. When work is done by contract the item of camp comes under general expense, but, as a contractor usually charges his men a small rental for houses or bunks, there are generally enough credits made to the camp account to balance it.

Plant.—In spite of the length of this tunnel, being such as to class it as a long tunnel, a compressor plant was not used, but an electric motor was installed and used in operating a motor car to haul material from the tunnel. The motor had been used on some other job and had to be repaired. The total charge for motor, supplies, repairs, operation and power was \$3,132.29. When the tunnel was finished the motor was sent to another tunnel that was being driven and a credit was made for the motor of \$1,696.36, and \$360 for power furnished for other purposes, leaving a net charge of \$1,165.93. The cost per cu. yd. of excavation was 3 cts.,

while the cost per lin. ft. of tunnel was 49 cts. In contract work this item would be classed under the head of plant.

Tools.—The tools used on the job were small ones for the excavation and timber work, with the exception of the electric locomotives and the cars for hauling earth and timber. The cost of the tools and supplies was \$6,520.04. The cost of repairing and maintaining these was:

Labor	\$2,684.95
Coal	135.38
Lumber	195.76
Iron	417.84
Total	\$3,433.73

This makes a total expenditure for tools of \$9,953.77. At the end of the job, a credit was made of \$3,929.16 for tools and supplies sent to another job, leaving a net charge for tools of \$6,024.61. This charge properly belongs under the item of plant, yet, inasmuch as the depreciation on small tools is much greater than on machinery, it is well to keep a separate account of tools. The cost per cu. yd. for tools was 17 cts., while the cost per lin. ft. of tunnel was \$2.55.

Explosives.—A car load of Forcite dynamite was bought for the job, but only a small part of it was used. The strength was 40 per cent, and it cost $12\frac{1}{4}$ cts per lb. Two 30-hole exploding batteries were bought, and electrical exploders to use with the batteries. The total cost of explosives was:

Dynamite and exploders.....	\$2,638.48
2 batteries	80.00
Wire	40.00
Total	\$2,758.48

At the end of the job, the batteries and unused explosives were sent to another piece of work. A credit of \$60 was made for the two batteries, and \$2,030.29 was credited for the explosives. Consequently there remained a net charge of \$468.19 for blasting. This makes a charge of 2 cts. per cu. yd. and 28 cts. per lin. ft. of tunnel.

Tunnel Excavation.—The excavation was done in the usual manner. The heading was excavated and timbered, then widened out and the roof supported in the manner shown in the illustrations, with the addition of temporary props. Then the bench was excavated and the permanent timbering finished. The excavated material was wheeled out of the heading in wheelbarrows, and horses were used in pulling the cars from the bench excavation to the dump, but as the haul became long, the electric locomotives previously referred to were used. Candles were used to give light in the headings, the expense for this being \$116.71. Electric wire was strung for the motors and also for lighting purposes. The costs for the hauling has been included in that for plant, but this work for the lighting and the power rented, with the lights, wires, etc., cost \$1,191.57, making a total cost of \$1,308.28. This makes a

cost of 4 cts. per cu. yd. for lights, and 55 cts. per lin. ft. of tunnel.

Another item of cost was some incidentals on the outside of the tunnel, such as small drains at street crossings, some clearing, a temporary trestle, the blocking up of a warehouse, and other details on which \$1,158.27 was spent for materials and labor. For these incidentals the cost per cu. yd. was 3 cts. and the cost per lin. ft. of tunnel was 49 cts.

The expenses for labor and teams was \$75,762.10, making a cost per cu. yd. of \$2 14 and per lin. ft. of tunnel of \$32.12.

Timber Lining.—The total amount of timber used was 2,434,200 ft. B. M., costing \$20,223.18. This is exclusive of wedges, cordwood and iron. Cordwood was used for packing, the plans calling for 533 cords, but only 451 cords were bought, the price per cord being \$1.50. The deficiency was made up by using old pieces of temporary timbers and scraps. The cost of the cordwood was \$658.16. Wedges were made from 2x12 boards, and cost to make from 1¼ to 2 cts. a piece. These were made by contract, about 15,000 being used, costing \$2,586.95. The iron and nails used cost \$669.79.

The amount of permanent timber called for by the plans was 1,687,200 ft. B. M. The average price paid for this was \$8.40 per M. In addition to this 747,000 ft. B. M. were used as temporary timbers and for other purposes. This cost an average price of \$8.10 per M. The cost of labor for framing and placing timber, exclusive of the time of the men from the mucking gangs that may have been used temporarily, was \$8,615.40. This gives a cost for framing and placing per M. ft. of timber as called for by the plans of \$5.10, while the cost per M. for the total amount of timber used was \$3.54. Separate record was not kept of placing the cordwood. The total cost of the lining was:

Lumber	\$20,223.18
Cord wood	658.16
Wedges	2,586.95
Iron	669.79
Labor	8,615.40
Total	<u>\$32,753.48</u>

The cost of each of these items per cu. yd. of excavation was:

	Per cu. yd.
Lumber, at \$8.30.....	\$0.57
Cordwood	0.02
Wedges	0.07
Iron	0.02
Labor	0.24
Total	<u>\$0.92</u>

The cost of lining per lin. ft. of tunnel was:

	Per lin. ft.
Lumber, at \$8.30.....	\$8.53
Cordwood	0.28
Wedges	1.09
Iron	0.23
Labor	3.65
Total	<u>\$13.83</u>

Personal Injury.—No one was killed in building this tunnel; however, a number of men were hurt, but none seriously. Various expenses were incurred on account of those injured, there having been paid out \$2,170.45, making a cost per cu. yd. of 6 cts., and per lin. ft. of tunnel of 92 cts.

Summary of Cost.—The total cost of the entire work was:

Engineering and superintendence.....	\$ 5,544.03
Camp	2,685.93
Personal injury.....	2,170.45
Plant	1,165.93
Tools	6,024.61
Expenses	652.19
Tunnel Excavation:	
Light	1,308.28
Incidentals	1,158.27
Labor	75,762.10
Timber Lining:	
Lumber	20,223.18
Cord wood	658.16
Wedges	2,586.95
Iron	669.70
Labor	8,615.40

Total\$129,241.27

The cost per cu. yd. for each of these items was:

	Per cu. yd.
Engineering and superintendence.....	\$0.16
Camp	0.08
Personal injury	0.06
Plant	0.02
Tools	0.17
Explosives	0.02
Tunnel Excavation:	
Light	0.04
Incidentals	0.03
Labor	2.14
Timber Lining:	
Lumber	0.57
Cord wood	0.02
Wedges	0.07
Iron	0.02
Labor	0.24

Total\$3.65

The cost per lin. ft. of tunnel for each item was:

	Per lin. ft.
Engineering and superintendence.....	\$ 2.35
Camp	1.14
Personal injury	0.92
Plant	0.49
Tools	2.55
Explosives	0.28
Tunnel Excavation:	
Light	0.55
Incidentals	0.49
Labor	32.12
Timber Lining:	
Lumber	8.53
Cord wood	0.28
Wedges	1.09
Iron	0.28
Labor	3.65

Total\$54.82

The total payroll on the job amounted to about \$90,000 and it will be noticed that the amount paid out for personal injuries was \$2,170.45. If liability insurance had been taken out for this job the rate would have been less than 2 per cent, hence money would have been saved. It is always well on construction work to carry this kind of insurance.

No record was kept of the slips and slides that occurred in the tunnel, but some must have occurred as glacial drift is apt to be treacherous material to tunnel through, and this must not have been an exception to the rule, as the large amount of temporary timber used bears witness.

Considering the high wages paid, and the fact that the work was done by day labor, the cost is not excessive, but no doubt timber was wasted, yet the prompt use of temporary timbers in some places may have saved money when heavy slips were threatened.

The engineering and superintendence together were less than 6 per cent of the total cost. This would mean that the engineering expense did not exceed 2 per cent, and the cost of locating the work is included in this. The item of general expense, as a contractor would have classified it, including superintendence, camp, and personal injury, was about 6 per cent. This could have been cut down a little by taking liability insurance, and charging rent for the camp. The plant and tool charge was a little more than 6 per cent. The tunnel lining was 25 per cent of the total cost.

The excavation of the heading was commenced in March. Work was started at both ends of the tunnel. During April no work was done inside the tunnel, but in May active operations were commenced and night and day forces were put to work. The headings were finished in August, and the benches cleaned up by the middle of September. Each heading foreman worked from 9 to 10 men, while the bench foremen worked from 15 to 20 men in their gangs. At one end of the tunnel a bench sub-foreman with extra men were used for several months. When work first commenced, the track gangs had from 10 to 15 men in them, there being a track gang for each end of the tunnel; but, as soon as the work was well under way, these gangs were cut down to 6 men each, and at the end only 4 men were kept in a gang. The timber gangs, consisted of a foreman, from 7 to 10 carpenters and a timber inspector. There was a night and day gang of carpenters from May to September.

Cost of Lining the Mullan Tunnel.—The tunnel is 3,350 ft. long, 20 miles west of Helena on the Northern Pacific Ry. Falls of rock and fires in the tunnel had caused numerous delays. The original timbering consisted of sets 4 ft. c. to c. of 12 x 12-in. timbers, with 4-in. lagging. The size was 16 x 20 ft. in the clear.

Concrete side walls (30-in.) and four-ring brick arch were built in place of the old timbering. A 7-ft. section was first prepared by removing one post and supporting the arch by struts. Two temporary posts were sent up and fastened by hook bolts; and a lagging was placed back of them to make forms to hold the

concrete. Several of these 7-ft. sections were prepared at a time, each two being separated by a 5-ft. section of the old timbering.

The mortar car delivered Portland cement mortar (1 to 3) through a chute, making an 8-in. layer of mortar into which broken stone was shoveled until all the mortar was taken up by the stone voids. In 10 to 14 days the walls were hard enough to support the arches which were then allowed to rest on the walls, and the posts of the remaining 5-ft. sections were removed, and concrete placed as before. About 4 parts of mortar were used to 5 parts of broken stone, which is a very rich concrete. The average progress per working day was 30 ft. of side wall, or 45 cu. yds. From 3 to 9 ft. of brick arch were put in at a time, depending upon the nature of the ground. To remove the old timber arch, one of the segments was partly sawed through, and a small charge of dynamite exploded in it; the debris being caught on a platform car, from which it was removed to another car and conveyed away. The center was then placed, and the cement car used to mix mortar on. Brick were $2\frac{1}{4} \times 2\frac{1}{4} \times 9$ ins., four ringings, making a 20-ft. arch and giving 1.62 cu. yds. per lin. ft. of tunnel. The bricks were laid in rowlock bond. Two gangs of 3 bricklayers and 6 helpers each, laid 12 lin. ft., or 19.4 cu. yds., of brick arch per day.

The foregoing description of the work is given by Mr. H. C. Relf. The following data were published in *Engineering-Contracting*, July 17, 1907.

For most of the distance it was lined with concrete side walls and concrete arch, but for part of the distance a brick arch was used instead of concrete. The brick was used only where it was necessary to support the roof by timbering, for wherever the roof would stand without props the concrete was used on account of its much greater cheapness.

The concrete side walls were 14 ft. high and had an average thickness of $2\frac{1}{2}$ ft. Therefore each side wall averaged nearly 1.3 cu. yds. per lin. ft., and the two walls averaged 2.59 cu. yds. per lin. ft. of tunnel. The concrete was mixed 1:3:5, being, we believe, unnecessarily rich in cement. The average amount of concrete placed in the walls per day was 50 cu. yds.

COST OF SIDE WALLS.

Materials:	Per cu. yd.
1.33 bbl. cement, at \$2.00.....	\$2.66

Materials	\$3.16
Labor on concrete.....	0.84
Labor removing timber, etc.....	0.95
Train service	0.75
Miscellaneous	0.34

Total **\$6.04**

In the two side walls there were 2.59 cu. yds. of concrete per lin. ft. of tunnel, hence the cost of the side walls was $\$6.04 \times 2.59 = \15.64 per lin. ft. of tunnel.

The concrete arch varied in thickness, averaging from 14 to 20 ins. at the springing line to 8 to 14 ins. at the crown. The arch averaged 1.2 cu. yds. per lin. ft. of tunnel. About 20 cu. yds. of arch were placed per day. The arch concrete was mixed 1:3:5 and the cost was as follows:

COST OF CONCRETE ARCH.

Grand total	\$10.35

It will be noted that the "train service" is an item that really should be considered as a part of the cost of the materials, for the cost of the sand and stone is the cost f. o. b. cars at the sand pit and at the quarry, to which should be added the cost of hauling them to the tunnel—to-wit, the "train service."

Summing up, we have the following as the cost per lineal foot for lining this single-track tunnel with concrete:

		Per lin. ft.
2.59 cu. yds. side walls, at.....	\$ 6.04	\$15.64
1.20 cu. yds. arch, at.....	10.33	12.40
2.79 cu. yds. Total.....	\$9.38	\$28.04

It should be remembered that the higher cost of the arch concrete is due in large measure to the fact that 1.8 cu. yds. of dry rock packing above the arch is included in the cost of the concrete. Strictly speaking, this dry rock packing should not be charged against the arch concrete, and, segregating it, we have the following:

		Per lin. ft.
2.59 cu. yds. concrete side walls, at.....	\$6.04	\$15.64
1.20 cu. yds. concrete arch, at.....	8.13	9.82
2.16 cu. yds. dry rock, at.....	0.55	1.19
Labor placing 2.16 cu. yds. at.....	0.64	1.39
Total		\$28.04

This is a much more rational analysis of the cost and a still further reduction in the cost of the arch concrete might be made by prorating the train service item (\$1.50 per cu. yd. concrete). At least half of this train service should be charged to the dry rock backing, for there are 1.25 cu. yds. of sand and broken stone to 1.80 cu. yds. of dry rock backing.

The amount of this dry rock backing, or packing, varies greatly in different parts of a tunnel. In the first half of this tunnel it averaged 1.8 cu. yds. per lin. ft., while in the second half it averaged

nearly 2.4 cu. yds. per lin. ft. In a subsequent issue we shall give the cost of lining a tunnel that averaged 1.4 cu. yds. of dry rock packing per lin. ft.

As previously stated, part of this tunnel was arched with brick instead of concrete. About one-third of the tunnel was thus arched with brick, laid 2 to 5 rings thick, and averaging 1.28 cu. yds. per lin. ft. of tunnel.

The average progress was 13 lin. ft. per day. The brick were 2¼x4x8 ins. in size. The cost of the brick arch was as follows:

<i>Materials:</i>		Per cu. yd.
500 brick, at	\$7.00	\$3.50
1.02 bbl. cement, at.....	2.00	2.04
0.4 cu. yd. sand, at.....	0.25	0.10
Total		\$5.65
1.5 cu. yds. dry rock backing at.....	\$0.55	\$0.83

Train service	1.50	
Miscellaneous	0.35	
Total	\$11.24	
Dry rock backing.....	0.83	
Labor placing rock backing.....	1.14	
Grand total	\$13.21	

The cost per lin. ft. of tunnel for lining with a brick arch resting on concrete side walls was as follows:

	Per lin. ft.
2.50 cu. yds. concrete side walls at \$6.04.....	\$15.64
1.28 cu. yds. brick arch at \$11.24.....	14.39
1.92 cu. yds. rock backing at \$0.55.....	1.06
Labor placing 1.92 cu. yd. rock backing at \$0.76	1.46
Total	\$32.55

The previous remarks about train service apply in this case also.

Not much has ever been published on the cost of tunnel lining. Several examples of such cost are given in Gillette's "Rock Excavation," but the costs there given are considerably higher than those above recorded. In making comparisons, however, the reader is cautioned to compare the cost per cubic yard of lining as well as the cost per lineal foot of tunnel. The character of the ground and the opinion of the engineer influence the thickness of the lining used, so that one tunnel may contain twice as many cubic yards per lineal foot as another tunnel of equal size.

Masonry lining put in at the time of construction is obviously cheaper than lining put in to replace an old timber lining. Not only does the passage of trains delay work, but the cost of removing the old timber lining is no small item itself. The work above described involved the removal of an old timber lining, yet it was done at a very low cost, particularly when one considers that it was done by company forces and not by contract.

Cost of Lining a 1,000 Ft. Railway Tunnel.*—This tunnel was lined with concrete side walls and a brick arch, the length of the lining being about 1,000 lin. ft. The two concrete side walls averaged 2.2 cu. yds. per lin. ft. of tunnel, and the cost was as follows, per cu. yd.

	Per cu yd.
1.1 bbl. cement at \$2.00.....	\$2.20
0.9 cu. yd. stone at \$0.60.....	0.54
0.5 cu. yd. sand at \$0.12.....	0.06
Tools	0.04
Light	0.01
Falswork, timber and iron.....	0.07
Labor excavating for and building side walls.....	1.76
Engineer and superintendence.....	0.15
Work train service.....	0.90
Total	\$5.75

Laborers received \$2.00 a day on the concrete work. We are unable to give the cost of the labor in as much detail as was given in our issue of July 17, but the total cost per cubic yard is nearly the same in both cases. The cost of the sand was merely the cost of loading. Work train service (90 cts. per cu. yd. of concrete) covers the cost of hauling sand and broken stone.

There were four rings of brick in the arch which averaged 1.8 cu. yds. per lin. ft. of tunnel. The brick measures $2\frac{1}{2} \times 3\frac{3}{4} \times 8$ ins. The cost of the brick arch was as follows per cu. yd.

**Engineering-Contracting*, Aug. 14, 1907.

Materials.	Per cu. yd.
1.1 bbls. cement at \$2.00.....	\$2.20
480 brick at \$7.00.....	3.36
0.4 cu. yds. sand at \$0.50.....	0.20

Summary of Tunnel Lining.	
	Per lin. ft.
3.2 cu. yd. concrete sidewalls at \$6.72.....	\$21.30
1.8 cu. yd. brick arch at \$9.63.....	17.33
Total	\$38.63
The two portals were of concrete and each contained 250 cu. yds.	
The average cost of each portal was as follows:	
	Per portal.
275 bbls. cement at \$2.00.....	\$ 550
225 cu. yds. rock at \$0.60.....	135
110 cu. yds. sand at \$0.12.....	13
Work train service.....	150
Lumber for forms.....	70
Labor, erecting and removing forms.....	140
Labor excavating for and building portals.....	500
Engineering and superintendence.....	50
Total	\$1,608
This is equivalent to \$6.45 per cu. yd. of concrete in the portals.	
The cost of two portals, \$3,216, distributed over a tunnel 1,000 ft.	
long, adds \$3.22 per lin. ft. to the cost of the masonry lining.	

Cost of a Brick and Stone Lining.—(The data on tunnels above described should be consulted for data on concrete lining.) Drinker gives the following data on the lining of Carr's Tunnel (825 ft.) on the Pennsylvania R. R. in 1868-1869. Brickwork: 609,000 brick in the arch (5 per cent broken and lost); 10.44 bushels of neat cement (no sand used in the mortar) laid 1,000 bricks, the mortar forming 30 per cent of the brick masonry; the arch was 25 ins. thick, 24½-ft. span and 9-ft. rise:

	Cost per M.
Bricks f. o. b.	\$ 8.80
Loss in handling.51
Unloading and delivering.	1.92
Laying.	5.84
Cement.	5.10
Total	\$22.17

Bricklayers received 40 cts. per hr.; helpers, 17½ cts. per hr.; carpenters, 27½ cts. per hr.; laborers, 17 cts. per hr.

Stonework: 1,730 perches (25 cu ft.) of rough masonry for side walls, presumably sandstone; 187 perches of ring stone; 25 perches wasted in dressing. The bench walls were 4 ft. wide at the bottom, 2 ft. at the top and 13 ft. high.

	Cost per perch.
Quarrying (1,730 perches)	\$ 4.80
Cutting (1,730 perches)	4.36
Hauling (1,942 perches)	1.06
Handling and laying (1,917 perches)	2.80
Cement, 1.65 bu. per perch (8 1/4 per cent of the Masonry)81
Total	\$13.83

Stone cutters and masons received 35 cts. per hr.; quarrymen, 17½ cts.; laborers, 17 cts. The stone side walls were laid in 8 courses averaging 2 ft. thick each; hence there were 52,800 sq. ft. of beds cut; and estimating each stone 3 ft. long and dressed for 1½ ft. back of the face on joints, there were 14,300 sq. ft. of joints, making a total of 67,100 sq. ft. of cutting which cost 11.2 cts. per sq. ft. This is said to have been too high a cost, if the measurements were correct.

Arch centering cost \$1,400, to which was added \$600 for moving the centering forward from time to time; making \$2.40 per lin. ft. of tunnel, to which must be added \$0.70 per ft. for scaffolding.

Weights and Price of Rails.—Steel rails are sold by the ton of 2,240 lbs. The standard price for many years past has been \$28 per ton at the mills, Pittsburg, Chicago, etc. Railways have charged one another ½ ct. per ton-mile freight on rails.

The number of tons of rails per mile of single track is exactly

11
— of the weight of the rail in pounds per yard of length. Thus a
7
track laid with 80-lb. rails will require $\frac{11}{7} \times 80 = 125.5 +$ tons per
7
mile of single track.

Prices of Rails Since 1876.*—We publish below the price of steel rails at Pittsburgh for the years 1876 to 1907 inclusive. We also include the price of iron rails from 1876 to 1882. After the last named date iron rails were seldom laid.

It will be noted that since 1888 the price of rails has never varied much from the present price, except in the years 1897 and 1898.

The Cost of Track Laying.†—Contracts for track laying on new railway construction are not at all uniform as to specified methods of payment, largely because of varying practice as to the time and method of ballasting. If the ballast is not placed at the time of track laying, it is customary to divide the payment for track work in two parts—(1) track laying and (2) surfacing track.

Track laying involves the unloading of the ties and rails from the cars, trimming the earth to true grade to receive the ties, delivering and placing the ties and rails thereon, curving the rails and joining them.

The railway company usually stands the cost of loading the ties, rails, etc., at the material yard and the transportation to the site of track laying work. This expense is charged upon the railway company's books as "train service."

**Engineering Contracting*, July 8, 1908.

†*Engineering-Contracting*, Oct. 7, 1908.

Surfacing track consists in shoveling earth in between the ties, aligning the track and tamping. Where suitable material for filling between the ties is not at hand, it is hauled in on cars at the expense of the railway company, and the contractor loads and unloads these cars at a separate unit price agreed upon. Such material if hauled in is usually gravel, and is called ballast.

On the Northern Pacific Railway the contract prices for track laying and surfacing have been quite constant for the last 30 years, being about \$250 per mile for track laying and \$200 per mile for surfacing. The engineer's preliminary estimates of the cost of "train service" have usually been about \$100 a mile, but the actual cost has ranged from \$75 to \$150 a mile. Summarizing we have:

	Per mile.
Tracking laying (contract price).....	\$250
Surfacing (contract price).....	200
Train service (including loading).....	125
Total	<u>\$575</u>

Of course the length of all permanent siding is included in arriving at the mileage.

In addition to this item of "train service" there is the cost of transporting workmen to the site of the work, for, under most contracts, the railway company agrees to carry the contractor's workmen free over its own lines. The railway also frequently agrees to carry the contractor's plant, including animals, free for some prescribed distance. This cost of transporting men and plant has seldom exceeded \$25 per mile of track. This brings the total cost up to about \$600 a mile. An allowance greater than this is usually an error on the side of liberality.

The item that we have called "train service" is commonly underestimated by engineers who have not had access to the books of railway companies, so that an analysis of items that go to make up this cost of train service will prove of decided value to the majority of railway engineers. Such an analysis follows:

	Per day.
1 engineman	\$ 3.60
1 fireman	2.00
1 conductor	3.00
2 brakemen at \$2.....	4.00
1 engine	7.50
14 flat cars at 35 cts.....	4.90
4 tons coal at \$3.....	12.00
Oil and waste.....	0.75
Total	<u>\$37.75</u>

In round numbers we may call it \$40 a day for a train and train crew.

It must be remembered that the train crew is paid by the month and not by the day. Hence the average number of miles of track laid per month should be divided by the total number of working

days in the month and not by the number of days actually worked in arriving at an average daily mileage for track laying to be divided into the cost of train service.

It must also be remembered that the number of trains required can not be determined by the average haul of materials, but by the longest haul from the material yards to the front.

Usually three trains are needed in building a long line, where the track laying gang is large enough to lay 2 miles of track a day when working. Due to spells of bad weather, delays occasioned by non-completion of bridges, etc., the monthly average will not be more than 40 miles, or 1.5 miles per working day. Hence 3 trains at \$40 equals \$120, which divided by 1.5 miles gives \$80 per mile for train service.

To this must be added the cost of unloading rails and ties in the material yard. The rails and fastenings weigh about 120 tons per mile, and the ties weigh about 200 tons per mile of track. Practically all the steel has to be unloaded and loaded again, but usually the ties are delivered with such regularity that only a small portion of them needs to be stored. Contract prices for loading rails at 10 cts. a ton are not uncommon, although the price frequently runs as high as 25 cts. By common forces, materials should be unloaded and reloaded for 25 cts. a ton. Hence, if all the track materials were thus handled, the yard expense would not exceed \$80 per mile of track. Under ordinary conditions not more than half the materials are thus handled in the yard, so that the yard cost averages about \$45 per mile of track. Adding this to the item of train service we have the total of \$125 per mile of track, as above stated.

Where all the track is to be ballasted at once, the present practice is to include the cost of "surfacing track" as a part of the cost of ballasting.

To indicate how the contract prices run under such conditions, we may cite the bids on the Portland & Seattle Ry., in 1906, which were as follows:

Track laying, including loading of track materials but not including unloading in the yard, \$300 per mile.

Tie plating (fully tie plated), \$75 per mile.

Labor on single tie plates, 1½ cts. each.

Labor on switches, \$25 each.

Ballast, 27 cts. per cu. yd.

This price is for gravel ballast and includes all the cost of loading and unloading the same and tamping it under the ties, and lining up the track, but does not include the train service nor the wear and tear on the steam shovel which is furnished by the railway company. The train service rarely exceeds 8 cts. per cu. yd. and another 1 ct. will usually cover steam shovel repairs and depreciation. This 9 cts. added to the contract price of 27 cts. gives a total of 36 cts. per cu. yd. of gravel ballast in place. This is a liberal estimate under ordinary conditions.

We give the following as confirming the above given estimate of \$150 per mile for "train service," yard work and transportation of men in track laying:

On the Seattle and Montana Ry., built in 1891, the train service, etc., cost \$67 per mile of track for 79 miles.

On the Idaho division of the Great Northern Ry. (110 miles long), built in 1892, the train service, etc., cost \$125 per mile of track.

On the Cascade division of the Northern Pacific Ry., built in 1884, the cost of train service, etc., was \$170 per mile of track. This was a difficult section over the Cascade Mountains. On an easier section the corresponding cost was \$150 per mile.

On the Snake River branch of the O. R. & N., built in 1893, the cost of train service, etc., was \$154 per mile, to which must be added \$18 per mile for the cost of transporting men, etc.

It will be seen from these figures that engineers quite commonly underestimate the total cost of track laying and surfacing. Frequently estimates may be seen that contain no allowance whatever for train service and work at the material yards.

Cost of Tracklaying, M., St. Paul & S. S. M. Ry.—About 263 miles of track were laid in 1892-3 from Valley City across North Dakota. The tracklaying and surfacing were done by the railway company, not by contract. The track was 72-lb. rails laid on 16 ties to the 30-ft. rail. The construction train was made up of 32 cars, the locomotive being in the middle of the train. The next car behind the locomotive was an ordinary flat car loaded with telegraph material; then followed 15 box cars loaded with ties. In front of the locomotive were the following cars, No. 1 being the one farthest front.

No. 1, Pioneer car. This was double deck, containing blacksmith shop, store room, general foreman's office, telegraph office, two sleeping rooms, and three extra berths. In front of the car was a platform carrying extra splice bars, bolts and spikes.

No. 2, store car. This was double deck, and had a store room for provisions and one for clothes, sleeping berths for cooks and a sleeping apartment above.

No. 3 and 4, dining and sleeping cars, double deck.

No. 5, kitchen car, single deck.

No. 6, dining and sleeping car, double deck.

No. 7, feed and fuel car, ordinary box car.

No. 8, water car, flat car with a 2,000-gal. tank at each end.

No. 9 to 16, flat cars with rails and spikes.

Work commenced at 7 a. m., the teams hauling ties from the five rear cars. The ties were shoved from the car down a tie chute, provided with three rollers, and were loaded into a V-shaped rack on a wagon holding 25 ties. The rails were unloaded onto the ground from both sides of the cars, and the train pulled back out of the way. The rails were loaded onto two "iron cars" and hauled to the end of the track by horses. The iron car gang would "drop" 100 rails (1,500 ft. of track) in half an hour. As soon as a pair was dropped upon the ties, a hook gage was thrown over them, at the forward end, and the horse pulled the car forward 30 ft. Two more

rails were then run out, and so on. The tracklaying force was as follows:

	Per day.
Iron car gang, who dropped rails, 22 men at \$2.25.....	\$ 49.50
Strappers, who adjusted and bolted splices, 6 men at \$2.00...	12.00
Spike peddlers, 2 men at \$1.50.....	3.00
Tie-spacing gang, 12 men at \$1.50.....	18.00
Men lining ties, with rope and stakes, 2 men at \$1.75.....	3.50
Men spacing joint ties, 2 men at \$1.75.....	3.50
Men leveling grade cut by tie wagons, 4 men at \$1.50.....	6.00
Spikers, 16 men at \$2.00.....	32.00
Nippers, holding up end ties for spikers, 8 men at \$1.50.....	12.00
Tracklining gang, 6 men at \$1.75.....	10.50
Teamsters for tie wagons (\$35 per mo. and board), 40 men at \$2.00.....	80.00
Men unloading ties from cars, 15 men at \$1.75.....	26.25
Men unloading rails and fastenings from cars, 4 men at \$1.75	7.00
Telegraph gang, 8 men at \$1.75.....	14.00
Telegraph operator (\$50 per mo.), 1 man at \$2.00.....	2.00
Drivers of iron car horses, 2 men at \$1.75.....	3.50
Blacksmith, 1 man at \$2.25.....	2.25
Night watchman, 1 man at \$1.50.....	1.50
Cooks (\$50 per mo.), 2 men at \$2.00.....	4.00
Baker, working nights, 1 man at \$2.50.....	2.50
Walters, 5 men at \$2.00.....	10.00
Storekeeper, 1 man at \$2.50.....	2.50
Foremen (\$65 per mo. each), 5 men at \$2.80.....	14.00
General foreman (\$150 per mo.), 1 man at \$6.00.....	6.00
Total	\$225.50

Note that the teams of horses are not included, but the drivers of the teams are included in the above. The men were boarded for \$3.50 a week, and this was deducted from the wages of all except teamsters.

The average daily wage of these 167 men was \$1.35.

The telegraph gang, consisted of 8 men and 1 foreman. The cedar poles were 25 ft. long, spaced 30 to the mile, set 5 ft. in the ground. The wire was stretched from a reel on a small hand wagon pushed by the men.

This force of 167 men and about 90 horses averaged 3 miles of track per day. If we consider horses (not including driver) as costing \$1 per day, we have a total daily cost of \$415.50, not including the cost of operating two locomotives and trains, which may be rated at \$40 each (including wages, fuel, interest and depreciation). This brings the total cost to \$495.50 per day, or \$165 per mile, including the erecting of the telegraph line, but not including the cost of surfacing the track. On one occasion the above force laid 4 miles in 10 hrs. In dry open country, like North Dakota, this method was faster than working with track machines and no more expensive. In swamp, very hilly or timbered country, the track-laying machines are especially serviceable.

The track surfacing gangs followed the tracklayers and surfaced the track so as to make a safe roadway and prevent bending of the rails and splices before the ballasting was done. These gangs numbered 40 to 45 men under a foreman and sub-foreman. About 250 men were required for surfacing, and they went to and from work on hand cars, their boarding cars being located on the sidings

which were put in about every 10 miles. If these men received \$1.50 per day, the surfacing cost \$375 per day, or \$125 per mile. Hence the total cost of laying and surfacing would be \$290 per mile.

Cost of Tracklaying, 50-lb. Rails.—In 1881 the following gang averaged one mile of track laid per day by contract. The track was not surfaced by this force.

This does not include the cost of "surfacing," nor does it include "train service."

Tie gang.	Per day.
1 panel spacer, at \$1.50.....	\$ 1.50
1 tie surfacer, at \$1.50.....	1.50
2 tie liners, at \$1.50.....	3.00
3 tie unloaders, at \$1.50.....	4.50
6 tie spreaders, at \$1.50.....	9.00
1 waterboy, at \$1.25.....	1.25
1 foreman, at \$3.00.....	3.00
Iron gang.	
1 gager, at \$2.00.....	2.00
2 heelers, at \$2.00.....	4.00
2 unloaders, at \$2.00.....	4.00
6 iron men, at \$2.00.....	12.00
1 waterboy, at \$1.25.....	1.25
1 foreman, at \$3.00.....	3.00
Front gang.	
1 tie spacer, at \$1.50.....	1.50
1 spike peddler, at \$1.50.....	1.50
2 nippers, at \$1.50.....	3.00
4 spikers, at \$2.00.....	8.00
6 strappers, at \$1.50.....	7.50
1 waterboy, at \$1.25.....	1.25
1 foreman, at \$3.00.....	3.00
Tie loading gang.	
16 men (4 gangs of 4 each), at \$1.50.....	24.00
1 waterboy, at \$1.25.....	1.25
1 foreman, at \$3.00.....	3.00
Backspiking gang.	
1 tie spacer, at \$1.50.....	1.50
2 spike peddlers, at \$1.50.....	3.00
4 nippers, at \$1.50.....	6.00
8 spikers, at \$2.00.....	16.00
1 waterboy, at \$1.25.....	1.25
1 foreman, at \$3.00.....	3.00
Lining gang.	
5 men, at \$1.50.....	7.50
1 waterboy, at \$1.25.....	1.25
Backfilling gang.	
15 men, at \$1.50.....	22.50
1 waterboy, at \$1.25.....	1.25
1 foreman, at \$3.00.....	3.00
Hauling gang.	
18 teamsters, at \$1.80.....	32.40
1 waterboy, at \$1.25.....	1.25
40 mules' feed, at \$0.40.....	16.00
1 wagon master, at \$3.00.....	3.00
General force.	
1 camp boss, teamsters' camp, at \$2.25.....	2.25
1 blacksmith, at \$2.25.....	2.25
2 night watchmen, at \$2.25.....	4.50
1 tool man, at \$2.00.....	2.00
1 bookkeeper, at \$4.00.....	4.00
1 superintendent, at \$5.00.....	5.00
Material train, fuel and wages.....	24.00
Total per day and per mile.....	\$266.90

The force, as above given, can lay $1\frac{1}{2}$ miles of steel track per day, but cannot keep up the back work and average much more than one mile. All ties are full spiked; 15 ties to a 30-ft. rail; 50-lb. steel rails. The ties and steel are delivered to the contractor on cars at the last side track; and side tracks are about 8 miles apart.

A material train is made up of 10 tie cars, each holding 135 ties, and 3 steel cars, each holding 60 rails. This train is at the boarding train at 6 a. m., in time to take the force to the front after breakfast. The backfillers, liners and backspikers are dropped where work had stopped the day before, and the 10 cars of ties (which are in the rear of the locomotive) are uncoupled far enough back to give the train room to move ahead with the 3 cars of steel (which are in front of the locomotive) as far as the "iron car" upon which 30 rails at a time are loaded and pushed up front. The two unloaders in the iron gang assist in loading the iron car; and, while the rails on the iron car are being laid, they throw off another 30 rails from the flat cars ready to be loaded on the iron car. The 10 cars of ties are brought up as fast as the track will allow, and only enough are unloaded by the tie loaders at one time to keep the wagons busy. At noon the train carries the force back to dinner, the empty flat cars are sidetracked, and another train of 10 tie cars and 3 steel cars brought up in time to take the men back after dinner.

In laying the track, the panel spacer with a 30-ft. pole and pick keeps far enough ahead to do duty as the roadmaster. The front gangs of spikers (2 on each rail) spike 3 ties in each panel, always the joint and the 6th and 11th ties, skipping 4 ties each time. Of the 5 strappers, one untrims the plates, leaving plates, nuts and bolts on the joint tie, and the other 4, working 2 on a side, strap up and bolt the joints. Should the backspikers get behind, they are assisted by the frontspikers. Should the backfillers get behind, they are reinforced by the tie gangs, and the iron gang and strappers can be putting in the sidings.

Of the teams, 16 are used to haul ties, 1 to pull the iron car, and 1 to haul water to the boarding train. The 16 teams haul 14 loads of 12 ties each per day, making 2,688 ties.

Cost of Tracklaying on the A., T. & S. Fe R. R.—With a well-organized force the cost of laying and surfacing the Arkansas City extension of the A., T. & S. Fe. in 1888, was \$393 per mile for a month's work. On the same road the following force laid 3 miles per day:

<i>Laying.</i>	<i>Per day.</i>
15 men running iron cars, at \$1.75.....	\$ 26.25
2 men unloading iron, at \$1.75.....	3.50
24 men spiking, at \$1.75.....	42.00
8 men strapping, at \$1.75.....	14.00
5 men spacing ties and "squaring" joints, at \$1.75.....	8.75
4 men lining track, at \$1.75.....	7.00
7 men setting "joint and center" ties, at \$1.75.....	12.25
2 men carrying gages, at \$1.75.....	3.50
2 men distributing spikes, at \$1.75.....	3.50
1 man caring for tools, at \$1.75.....	1.75
48 men bedding ties, at \$1.40.....	58.80
12 men ("nippers"), at \$1.40.....	16.80
18 men handling ties, at \$1.40.....	25.20
2 men stretching tie line, at \$1.40.....	2.80
4 men carrying water, at \$1.40.....	5.60
1 general foreman.....	3.33
1 foreman iron car.....	2.50
1 foreman tie bedding.....	2.50
1 foreman handling ties.....	2.50
1 foreman tracklining.....	2.50
1 foreman spiking gang.....	2.00
10 extra men, at \$1.40.....	14.00
22 teams hauling ties, at \$3.50.....	77.00
1 team hauling iron car, at \$3.50.....	3.50
Total laying 2 miles at \$170.76.....	\$341.53

In addition to this the surfacing of 2 miles of track per day cost as follows.

<i>Surfacing.</i>	
30 shovelers, at \$1.40.....	\$112.20
2 "back-bolters," at \$1.75.....	3.50
1 foreman raising track.....	2.00
1 foreman.....	2.50

Total surfacing 2 miles at \$60.10.....\$120.20

Train Service and General.

Superintendent of tracklaying.....	\$ 5.00
Timekeeper.....	2.00
Train and engine crews.....	15.04
Engineering.....	10.97

Total, train crews, etc., 2 miles at \$17.00.....\$34.01

Summary.

	<i>Per mile.</i>
Tracklaying.....	\$170.76
Tracksurfacing.....	60.10
Train service, etc.....	17.00
Total.....	\$247.86

This does not include the cost of supplying and distributing of ballast by train. On the Larned branch 15 miles were laid in 7 days, but under the favorable circumstance of light grades, light work, light earth for ballast, and roadbed in first-class condition.

It will be noted that the cost of "train service" appears not to include the delivery of materials from material yards, nor does it include fuel, and interest and depreciation on plant.

Cost of Tracklaying, A., T. & S. Fe R. R.—Some rapid work was done (1899) in the extension of the A., T. & S. Fe Ry. from Stockton, Cal., to Port Richmond. The rails were laid with broken

joints, 17 ties per rail. One stretch of 11 miles (62½-lb. rails) was laid at the rate of 2,846 ft. per day, with a force of 46 men, on level grade. Another stretch of 17 miles (76-lb. rails) was laid at the rate of 3,600 ft. per day, with 48 men, on a descending grade of 1%, with curves at intervals of ¼ mile. The best day's work, on the level grade, was 5,400 ft., with 52 men. The force was as follows:

Foreman	1
Sub-foreman	3
Strappers	4
Iron car men.....	10
Spikers	8
Nippers	4
Tie line man.....	1
Lining ties.....	2
Tie plater.....	1
Spike peddler.....	1
Spacing ties.....	2
Spacing rails.....	3
Back bolting	2
Tie carriers.....	10
Picking up materials.....	1
Total	52

Cost of Tracklaying, P., S. & N. R. R.—Mr. G. C. Woollard gives the following on tracklaying on the Pittsburg, Shawmut & Northern R. R. The length of track laid was 8 miles. With a gang of 46 men and 3 foremen the average day's work was 2,870 ft. of track laid; the best day's work was 3,290 ft. There were 18 men and a foreman in the tracklaying gang, 17 men and a foreman in the supply gang; 11 men and a foreman in the backtailing gang. Beside these men there were a locomotive engineer, fireman, conductor and a brakeman. No teams were used. Trucks passed one another by raising one truck to a vertical position on the cross-ties and then allowing it to drop back to an oblique position, keeping it from turning over by means of a prop while the loading truck passed. There were 18 oak ties to a rail, and rails were 85-lb. All the work was on a 2% down grade, which facilitated delivery of materials by gravity.

Cost of Tracklaying with Machines. — Tracklaying machines do not lay the track, but merely facilitate the delivery of ties and rails on a series of rollers from the cars to the tracklaying gang of men. In rugged or swampy country a tracklaying machine is especially economic, because the ties cannot be easily delivered by teams.

With a Holman tracklaying machine, 120 miles of the Washington County Ry. (Maine) were laid in 1899. The best day's work was 3 miles laid in 9 hrs. with 110 men.

On the Burlington & Missouri River Ry., with a gang of 86 men and a Holman machine, 1½ miles per day were laid at a cost of \$100 per mile. The rails were 85-lb. rails, with 18 ties to a rail. Curves of 1° to 1½° were laid. Equally good work was done with the Harris tracklaying machine.

On the Chicago, Rock Island & Pacific Ry., 1,300 miles of track were laid with a Harris machine in 1886 and 1887. The average cost of laying 2 miles per day was as follows:

	Per day.
1 general foreman.....	\$ 5.00
2 assistant foremen, at \$3.....	6.00
109 laborers, at \$2.....	218.00
1 engine and train crew.....	20.00
Total, 2 miles, \$124.50.....	\$249.00

To this must be added \$10 per mile for preparatory work in transferring material to cars in the yard, and \$5 per mile royalty for use of the Harris machine, bringing the total to \$140 per mile. It will be noted that this does not include the cost of surfacing.

The Harris machine is said to be quicker than the Holman, where long stretches are to be laid; but the Holman is more economical for short stretches or where delays are frequent, as the gang is smaller.

Another machine that has been extensively used is the Roberts.

The Hurley Tracklaying Machine Co., of Chicago, make an excellent machine with which 2 to 4 miles per day can be laid and quarterspiked with a gang of 40 men.

Cost of Laying a Narrow Gage Track.—Where ties and rails are dumped along in small piles, and where no grading has to be done, a gang of 3 men will average 210 ft. of track laid in 10 hrs. This applies to a light 3-ft. gage track made of 30-lb. rails on 6 x 6-in. ties, 5 ft. long, spaced 3-ft. centers. With wages at 15 cts. per hr., the labor cost is practically 2 cts. per ft. of track, or \$100 per mile, after the materials are delivered.

A Method of Unloading Rails.—An effective method of unloading rails, along a track where new rails are to be put in, is as follows: The car is provided with a tail board that hangs down and drags along on the track, forming an inclined plane. A hook on a rope is hooked into a rail, and another hook, on the other end of the rope, is hooked over a tie. As the car moves slowly forward the rail is dragged out. By having two of these ropes and hooks, pulling out two rails at a time, 71 rails were unloaded in 25 mins. from a drop end gondola, and 86 rails in 42 mins. from a solid end gondola.

Cost of Renewing Rails on the C., C., C. & St. L. Ry.*—The following is given by Mr. John Barth, and relates to the cost of taking up 30-lb. rail and laying 30-lb. rail.

To unload the new rail I used a rail unloader, which was operated by air, furnished by the work engine, which took a foreman and five men besides the train crew to operate. Any good handy man could run the loader. I made comparison with loading and unloading rail, and found that we could handle the rail considerably

**Engineering-Contracting*, Oct. 6, 1909.

cheaper with the machine. It cost to unload the new rail and fastenings, per mile:

Labor	\$ 9.75
Work train service.....	9.58
Fuel, oil and waste.. ...	7.58

Making, per mile for unloading, a total of.....\$26.91

This was on single track where we had an average of 17 trains during the 10 working hours. To get the above estimate of cost of unloading I took total cost of unloading 85 miles of rail, and divided by 85 which gives the average cost per mile. Some days we were hung up on account of trains and did very little work, and other days we could do more.

We loaded the old rail with the rail loader, and it cost practically the same to load it as it did to unload the new rail.

In laying this rail I used gangs of one foreman, assistant foreman, timekeeper, and two flagmen, and 44 men. Had my gangs organized as follows:

Six men with claw-bars pulling spikes.

Three men with spike mauls to loosen up spikes that were stuck and to knock down stubs.

Four men throwing out the old rail.

One man with nipping bar to cant the old rails up out of the old bed, and 3 men to shove it out.

Three men driving plugs in the old holes, which should be distributed ahead of the work.

In taking up light rail and laying heavier rail, pull the outside spikes. In doing this, I had 1 man with an adze to adze off the very highest ties only and to cut off the plugs that stick up.

Twelve men with tongs to set in the new rail, which should be set in one rail at a time.

One good hustling fellow to put in the expansion shims and keep the rail gang moving, using steel cut nails for shims, making the expansion according to the thermometer by using different sizes of nails, putting the nail in crosswise against the ball, so that it will be out of the way in putting on the angle bars. The first few trains over, this nail will slip out.

Two men with bars with claws on one end and pointed on the other to shove the rail into the spikes at center and quarters.

Four men with spike mauls. These men start off leaving eight ties unspiked between each man, and go ahead, each man spiking every eighth tie from the last one that he spiked. This spikes every other tie, and prevents the men running around each other.

One man with a claw bar and adze to pull out the spikes that come in the way of the angle bars at the new joint, and to adze down the high ties at the new joint.

Five men putting on angle bars, and bolting up, putting two bolts at each joint, all bolts and angle bars to be distributed ahead of the rail laying for each day's work only. Have plenty of wrenches and spike mauls, and when connection is being made, or waiting for

trains, turn the men that are working in the tong gang and those throwing out rail, back to do full bolting and full spiking.

Two men with a push car, to keep the connection rails, off-set splices, and everything needed in making a connection, and extra tools, right up with the rail-laying, so that when connection is to be made they will be on the ground. Have the spikers and bolters in starting out assist these two men in loading the connection rails. Always move the last new rail ahead and use it as a connection rail all the way through. This will always give you a good joint.

The foreman should watch the time of the regular trains, and go ahead of the spike pullers, and pick out his place for making a connection, and have four picked men out of the gang that set in the rail to make the connection, using short pieces of rail. I used pieces from 4 ft. to 4 ins. long and used off-set bars from 90 lbs. to 80 lbs. I always found that my new rail fell short. I was putting down 33-ft. rail and taking up 30-ft. rail, and every ten rail lengths we could make a good connection by pulling the 80-lb. rail against the 90-lb. and using short pieces of 80-lb. rail to fill in the gap. In closing up at night, if I thought it necessary, I would cut in a long piece of rail.

The two men handling the push car and keeping the tools and connections up with the rail laying, should also keep the tools in good repair, such as keeping handles in the mauls, and have a general supervision of the tools.

The assistant foreman should be back among the workmen and see that the track is kept safe spiked and bolted, and ready for trains by the time a connection is made.

Section men should follow up and tamp any ties that may be hanging or shim them up as the season of the year may require.

Gage the track when you space the ties, as you will have to do it at that time any way, and it avoids cutting up the ties with spikes.

In taking up 80-lb. rail and putting down 90-lb. rail, pull the outside spikes of both rails. In doing this you avoid adzing, as the new rail will set up on the shoulder of the tie on the outside and give the wheels a full bearing on the ball of the rail. In taking up and laying rail of the same size, pull the inside spikes on both rails, and adze the ties down so as to give the wheel a perfect bearing on the ball of the rail. To do this it would take five extra men to do the adzing above the 44.

Full bolt and spike the new rail and uncouple the old rail as far as you go each day. This usually can be done while waiting on trains. If not, take the time to do it. This is the reason I did not work larger gangs of men, as 44 or 46 men just about cleaned up each day's work even.

This rail laying was done on single track where we had an average of 17 trains in our 10 working hours, and was laid at a cost of \$134.24 per mile. We laid an average of 3,500 ft. of rail per day.

Since there are 141 tons of 90-lb. rails per mile, this cost is equivalent to \$0.95 per ton.

Rail Relaying Gang.*—At the last annual convention of the Roadmasters' and Maintenance of Way Association a committee report was read on relaying rail and the organization for the work. According to the report 51 men will make a good rail gang for 85 to 100-lb. rails, this gang being made up as follows: 1 foreman, 1 assistant foreman, 12 men on the tongs, 7 men pulling spikes, 6 men adzing, 1 man plugging spike holes, 4 men throwing out old line of rails, 10 men spiking, 5 men bolting, 2 flagmen, 1 tool man, and 1 water man. All rails should be laid one at a time, except in a yard where business is too heavy to permit of the use of the tracks. Heavy adzing should, if possible, be done in advance of rail laying.

A gang of this size can lay one mile of track per day on the average railroad. At this rate, and assuming wages to average \$2 per man, it would cost \$100 per mile for relaying rails.

Labor Cost of Renewing Rails.—During a traffic of one train per hour, in winter, the cost of taking up old rails, unloading and placing new 72-lb. rails on a single track, was \$140 per mile. The wages of common laborers were \$1.25 per 10 hrs.

Labor Cost of Renewing Rails.—In 1904 and 1905, old 72-lb rails were taken up and new 85-lb. rails laid on certain sections of track in the state of Washington at the following costs per mile. The first work involved 27 miles of single track.

	Per mile.
Unloading and distributing.....	\$ 34.60
Laying and surfacing.....	294.15
Picking up and piling old steel.....	38.15
Total	\$366.90

Since 85-lb. rails weigh 134 tons per mile, the labor cost of renewing these rails was \$2.75 per ton.

On another 18-mile stretch, the cost was as follows:

	Per mile.
Unloading and distributing.....	\$ 35.05
Laying and surfacing.....	393.70
Picking up and piling old steel.....	28.60
Total	\$467.35

This is equivalent to nearly \$3.50 per ton, which is an unnecessarily high cost. The wages of laborers were \$1.75, and of spikers \$2.25 per day.

Cost of Laying Side Tracks and Switches.†—Practically nothing has ever been printed as to the cost of laying sidetracks and spurs. We purpose giving in this article eight examples of the actual cost of this sort of work on a western railway.

The grading was done, in most cases, by contract and its cost is not included in the following costs, unless specifically mentioned. The tracklaying and surfacing were done by company forces.

*Engineering-Contracting, Jan. 15, 1908.

†Engineering-Contracting, Nov. 4, 1908.

Example 1.—This is a spur track 400 ft. long.

Labor.	
8 days, foreman at \$1.50.....	\$12.00.
16 days, laborers, at \$1.25.....	20.00
Total labor, 400 ft. at \$0.08.....	\$32.00
Materials.	
158 cedar ties at \$0.35.....	\$ 55.30
1 set stub switch ties, 3,200 ft. B. M. at \$15....	48.00
800 ft. S. H. (second hand), 56 lb. rail, 6 and 1836/2240 tons at \$16.....	109.31
52 S. H. angle bars, 728 lbs., at \$1.37.....	9.97
100 S. H. track bolts, 85 lbs., at \$1.95.....	1.66
400 lbs. new spikes at \$1.85.....	7.40
1 frog (56 lb.).....	8.00
1 S. H. switch lock.....	0.25
2 S. H. 2 way switch chairs, 190 lbs., at \$1.65..	3.14
6 connecting rods, 5' 2", at \$1.35.....	8.10
1 S. H. long connecting rod.....	2.50
1 high switch stand, 2 way.....	8.00
Total materials.....	\$261.63
Grand total, 400 ft., at \$0.73.....	\$293.63

Example 2.—This work involved putting in a switch to connect two tracks, the length of track laid being 118 ft.

Labor.	
4½ days, foreman at \$1.80.....	\$ 8.10
14½ days, laborer at \$1.25.....	18.13
4 days, laborer helping engineer stake out spur, \$1.25	5.00
Total labor, 118 ft. at \$0.265.....	\$31.23
Materials.	
19 S. H. switch ties at \$0.10.....	\$ 1.90
1 set switch ties, 2,677 ft. B. M. at \$14	37.48
108 ft. new 75 lb. rail, 1 460/2240 tons, \$27....	32.54
127 ft. S. H. 75 lb. rail, 1 935/2240 tons, \$16....	22.68
22 new 25 lb. angle bars, 528 lbs., \$1.45.....	7.66
62 track bolts, 52.7 lbs., \$2.00.....	1.05
256 track spikes, 143.4 lbs., \$1.68.....	2.41
1 new 75 lb. 1-7 frog.....	16.65
1 new sw. lock.....	0.46
1 S. H. sw. stand, 2 way, low.....	4.40
2 new switch points (75 lb.) at \$7.40.....	14.80
12 new tie plates at \$0.25.....	3.00
8 new rail braces at \$0.155.....	1.24
1 main rod.....	0.96
3 connecting rods at \$0.50.....	1.50
8 clips at \$0.27.....	2.16
24 clip bolts, 12 lbs., at \$3.10.....	0.37
1 S. H. short connecting rod.....	1.10
Total materials.....	\$152.32
Grand total, 118 ft., at \$1.55.....	\$183.55

Example 3.—This work consisted in putting in a passing track 2,500 ft. long.

Labor tracklaying.	
20 days, foreman at \$1.80.....	\$ 36.00
78 days, laborer at \$1.35.....	105.30
Total labor, 2,500 ft. at \$0.056.....	\$141.30

Materials.

2 S. H. head blocks, 224 ft. B. M., at \$6.....	\$ 1.34
1,245 S. H. ties at \$0.145.....	180.53
2 sets sw. ties, 34,045 ft. B. M., at \$20.00.....	68.09
42 planks (3 x 12-16), 2,016 ft. B. M., at \$11....	22.17
4,969 ft. S. H. 56 lb. rail, 41 911/2240 tons, at \$16	662.51
340 S. H. A bars, 4,590 lbs., at \$0.88.....	40.39
182 new trk. bolts, 155 lbs., at \$1.85.....	2.86
592 S. H. trk. bolts, 503 lbs., at \$1.40.....	7.04
5,100 spikes, 2,856 lbs., at \$1.65.....	47.12
2 frgs (1-9), 60 lbs., at \$13.25.....	26.50
2 H. T. 2 way sw. stands at \$7.25.....	14.50
2 long conn. rods at \$2.10.....	4.20
2 S. H. conn. rods at \$1.05.....	2.10
14 S. H. conn. rods at \$0.52.....	7.43
8 sw. stand bolts, 12 lbs., at \$2.25.....	0.27
8 sw. nuts.....	0.23
40 sw. chairs (60 lb.), 357 lbs., at \$1.45.....	5.18
2 sw. locks at \$0.29.....	0.58
2 S. H. guard rails (60 lbs.) at \$1.27.....	2.54

Total materials.....\$1,695.67

4,720 cu. yds. grading at 13 cts..... 613.60

Labor ballasting.

5½ days, foreman at \$1.80.....\$ 9.90

11 days, laborer at \$1.35..... 14.85

Total labor ballasting.....\$ 24.75

Grand total, 2,500 ft., at \$0.75..... 1,875.32

Example 4.—The work consisted in laying a passing track 2,500 ft. long, including grading, ballasting and surfacing.

Labor grading:

15 days, foreman at \$1.80.....\$ 27.00

10 days, laborer at \$1.25..... 22.48

195 days, team at \$3.50..... 682.50

Total grading.....\$ 731.98

Labor laying track.

4 days, foreman at \$1.80.....\$ 7.20

80 days, laborer at \$1.25..... 100.00

Total, 2,500 ft. at \$0.043.....\$ 107.20

Labor moving a switch.

1 day, foreman.....\$ 1.80

8½ days, laborer at \$1.25..... 10.63

Total\$ 12.43

Labor surfacing track.

4 days, foreman at \$1.80.....\$ 7.20

20 days, laborer at \$1.25..... 25.00

Total\$ 32.20

Work train service ballasting.

1.4 days, engine service (140 mi.) at \$27.50...\$ 38.50

15 days, conductor at \$80 mo..... 4.44

3 days, brakeman at \$60 mo..... 6.67

Total\$ 49.61

Materials.

4,760 lin. ft. S. H. 56 lb. rail, 39 1493/2240 tons, at \$16.....	\$ 684.66
128 lin. ft. S. H. 50 lb. rail, 2133/2240 tons, at \$16.....	15.24
1 new No. 9 frog.....	13.25
1 new No. 1 frog (56 lb.).....	12.25
4 guard rails at \$1.27.....	5.08
1,088 ties at \$0.23.....	250.24
2 sets sw. ties, 5,354 ft. B. M., \$12.00.....	64.25
4 H. B. bolts, 12 lbs., \$2.25.....	0.27
318 S. H. 56 lb. A bars, 4,462 lbs., \$0.88.....	39.18
2 sw. stands, \$7.25.....	14.50
12 S. H. 50 lb. splice bars, 108 lbs., \$0.88....	0.95
8 sq. nuts, 2 lbs., \$2.90.....	0.06
648 new track bolts, 551 lbs., \$1.85.....	10.19
2 sw. locks, \$0.45.....	0.90
4,990 new track spikes, 2,974 lbs., \$1.65.....	46.11
2 long conn. rods, \$2.10.....	4.20
4 new 2 way sw. chairs, cast 382 lb., at \$1.45	5.54
2 new tie rods, \$1.10.....	2.20
10 new conn. sw. rods, \$1.10.....	11.00
8 rail braces, \$0.91.....	0.73
12 crossing plank (3 x 12—16), 576 ft. B. M. at \$10.00.....	5.76
12 lbs. spikes, \$1.85.....	0.22
2 sets frog blocking, \$1.20.....	2.40
Total materials.....	\$1,129.18
Grand total, 2,500 ft. at \$0.829.....	\$2,072.60

Example 5.—This is an industry spur 550 ft. long, and the cost of labor only is given. The rail was 56-lb., and the cost of materials can be easily estimated from the examples previously given.

10 days, foreman, \$1.80.....	\$ 18.00
30 days, laborer, \$1.50.....	45.00
24 days, team and driver, \$4.00.....	96.00
Total, 550 ft., at \$0.28.....	\$159.00

Note the high cost due to team work.

Example 6.—This consisted in making an extension 180 ft. long to an existing spur, so that no switch was put in.

Labor:

3.6 days, foreman, at \$55 mo.....	\$ 6.75
11.6 days, labor, at \$1.50.....	14.16
4.8 days, labor, at \$1.20.....	5.04
Total labor, 180 ft., at \$0.144.....	\$25.95

Material:

360 ft. S. H. 60-lb. rail, 3 480/2240 tons, \$24.20...\$	77.79
24 S. H. A. bars, 342 lbs., \$1.53.....	6.23
190 track spikes, 106 lbs., \$1.59.....	1.69
48 S. H. tr. bolts, 41 lbs., \$2.04.....	0.84
90 treated ties, \$0.26.....	23.40
Total	\$117.95
Grand total, 180 ft., at \$0.80.....	\$143.90

Example 7.—This consisted in building an industrial spur 550 ft. long. The low cost of the labor should be noted, as compared with that in Example 5, where an inordinately high team cost appears.

Engineering:

8 hrs. asst. engr., at \$100 mo.....	\$ 2.58
8 hrs. roadman, at \$50 mo.....	1.29
8 hrs. chainman, at \$40 mo.....	1.03

Total engineering\$ 4.90

Labor:

55 hrs. foreman, at \$55 mo.....	\$ 9.75
475 hrs. laborer, at \$1.25 day.....	59.20

Total labor, 550 ft., at \$0.126.....\$ 68.95

Material:

1,052 ft. S. H. 56-lb. rail, 19,637 lbs., at \$24.30..	\$212.10
30 ft. scrap rail (56-lb.), 560 lbs., at \$7.37..	1.84
76 A bars (56-lb.), 1,082 lbs., at \$2.25.....	27.63
122 lbs. tr. bolts, at \$3.19.....	4.12
700 lbs. tr. spikes, at \$2.98.....	18.06
1 rigid frog (1-9), 60-lb.....	21.06
1 sw. stand	0.68
4 sw. bolts	0.20
1 long conn. rod.....	2.32
1 split sw. compl. (60-lb.).....	23.52
2 guard rails, 10 ft., 50-lb.....	6.56
12 S. H. rail braces, 8½ cts.....	1.02
1 sw. lock	0.38
1 set sw. ties, 3,282 ft. B. M., at \$8.50.....	27.91
1 sand bumper	9.20

Total materials\$362.59

Grand total\$436.44

It will be noted that no charge for cross ties (other than the set of sawed switch ties) is made. Hence the cost of materials is incomplete.

Example 8.—This is a crossover track, 496 ft. long.

Engineering:

1 day, asst. engr.....	\$ 2.75
1 day, rodman	1.80
1 day, chainman	1.30
Engr. expense	4.25

Total\$ 10.00

Labor:

Putting in sw. ties and grading new crossover track:

1.5 day, foreman, at \$75 mo.....	\$ 3.75
1.5 day, timekeeper, at \$60.....	3.00
1.5 day, asst. foreman, at \$60.....	3.00
38 day, laborers, at \$1.75.....	67.35

Total\$ 77.10

Putting in crossover track:

1 day, foreman, at \$75.....	\$ 3.42
1 day, timekeeper, at \$60.....	1.93
1 day, asst. foreman, at \$60.....	1.94
39.8 day, laborers, at \$1.75.....	69.65

Total\$ 75.94

Surfacing crossover track:

0.4 day, foreman, at \$75.....	\$ 0.97
0.4 day, asst. foreman, at \$60.....	0.97
0.5 day, timekeeper, at \$60.....	0.96
11.5 day, laborers, at \$1.75.....	20.10

Total\$ 22.80

Materials:

50 ft. 80-lb. 1st qual. rail, 1,333 lbs., at \$29.30..	\$ 17.43
87 ft. 80-lb. 2d qual. rail, 1 80/2240 tons, at \$29.80	28.89
\$79 ft. S. H. 68-lb. rail, 6 1951/2240 tons, at 24.20	166.27
41 S. H. ties, at \$0.10.....	4.10
130 treated ties, at \$0.37.....	48.10
1 set sw. ties.....	27.81
1 set sw. ties.....	22.51
14 new 24-in. 80-lb. A bars, 290 lbs., \$1.30...	3.77
2 new W. joints, \$0.96.....	1.92
50 S. H. 36-in. 68-lb. A bars, 1,200 lbs., \$0.98..	11.76
4 new 24-in. offsets, 68 lbs., \$1.37.....	0.93
125 new tr. bolts, 157 lbs., \$2.48.....	3.89
1,321 new spikes, 745 lbs., \$1.88.....	13.97
1 new No. 9 sprg. rail frog (77 1/2-lb.).....	35.50
1 new No. 7 frog (68-lb.).....	13.70
1 S. H. sw. stand.....	2.98
1 new sw. stand.....	5.55
8 sw. stand bolts, 14 lbs., \$3.66.....	0.51
1 sprg. switch comp., 15 pta. (68-lb.).....	18.11
1 sprg. switch comp., 15 pta. (68-lb.).....	9.41
1 S. H. long conn. rod.....	0.70
1 short conn. rod.....	0.34
2 guard rails comp. (80-lb.).....	12.65
2 S. H. 68-lb. guard rails, 680 lbs., \$13.80..	4.19
2 sw. locks repd., \$0.18.....	0.36
2 sets frog blocking, \$0.15.....	0.30
1 sw. lamp	1.85
68 new tie plates, 273 lbs., \$2.15.....	5.87
415 S. H. tie plates, 1,177 lbs., \$1.875.....	22.07
9 S. H. wall rail braces, 23 lbs., 11.05 cts..	0.12

Total material\$486.56

Grand total, 496 ft., at \$1.366.....\$672.40

The high cost of the labor is attributed to "extra labor expended in clearing and to considerable interference by switch engine, this work being done in the yards."

Summary.—On short sidetracks or cross-overs the cost of putting in a switch constitutes a much larger percentage of the total cost than on long sidetracks. Hence the cost of labor, as well as of materials, is greater per lineal foot of short sidetrack than of long sidetrack.

Estimated Cost of Growing Tie Timber.*—In a paper read before the Engineers' Club of Philadelphia, Mr. E. A. Sterling, Forester of the Pennsylvania Lines, stated that in their work on the Pennsylvania Lines east of Pittsburgh and Erie, over 2,000,000 trees had been planted on lands acquired in connection with widening and straightening the main line, and in the construction of low

**Engineering-Contracting*, April 22, 1908.

grade lines. The actual cost of plant material and planting last spring was \$11.29 per thousand trees.

Mr. Sterling gave the following as an estimate of the returns per acre, which may be expected from such work, if red oak is planted on land valued at \$10 per acre, with interest at $4\frac{1}{2}\%$, compounded annually, and the crop maturing in 40 yrs.:

Land at \$10, at $4\frac{1}{2}\%$, for 40 yrs.....	\$ 58.16
Plant material and planting \$10, at $4\frac{1}{2}\%$ for 40 yrs.....	58.16
Taxes, 3 cts. per annum, at $4\frac{1}{2}\%$ for 40 yrs...	3.21
Management and protection, 15 cts., at $4\frac{1}{2}\%$ for 40 yrs.....	16.05
Sawing or hewing 400 ties, at 10 cts.....	40.00
Hauling 400 ties, at 5 cts.....	20.00
Total, 400 ties, at 48 cts.....	\$195.58

By the above estimate 400 ties would be produced per acre every 40 yrs. at a cost of 48 cts. each, including compound interest charges at $4\frac{1}{2}\%$. Mr. Sterling states that the estimate of 40 yrs. will hold for red oak and Scotch and red pines; while chestnut should make ties in 30 to 35 yrs. and locust in 25 to 30 yrs., if not eaten up by the borers. The trees at the end of this period should average 15 ins. on the stump. The tax rate of 3 cts. per acre, used above, is far below the present rate, but is what would be considered a fair charge in a European forest.

Cost of Making Hewed Ties.—From a pine tree that is 14 ins. diameter at the height of a man's shoulder, from 3 to 5 pole ties may be made. The ties are hewed 8 to $8\frac{1}{2}$ ft. long, 6 ins. thick, with two hewed faces 3 ins. wide, and the bark on the sides is peeled with a tie peeler. It is said that a skillful man can cut and make 40 to 50 of these ties per day, but it would not be safe to figure on such an output. In the state of Washington, 25 to 35 fir ties per man per day are a fair output. This includes cutting down the small fir trees from which the ties are made. The men who do this work are called "tie hackers."

In Missouri 25 white oak ties per man per day are regarded as a good output, the men receiving 10 cts. per tie.

A Cheap Way of Loading Ties.—The following described device is simple and well adapted to handling other materials than ties. It consists of an overhead trolley, traveling on a 4-in. I-beam that serves as a rail. In loading box cars with ties, one end of this I-beam is supported on a light wooden A-frame, 7 ft. high and standing about 15 ft. from the car door; the other end of the I-beam enters the car door, and inside the door it is fastened to two bars ($\frac{1}{2} \times 3$ ins.) that branch, forming a Y with curved branches, so that one trolley can run toward one end of the car, another trolley toward the other end. The trackway in the car is hung from the roof rafters by clamps. From each of the trolleys is suspended, by a chain, an L-shaped tie stirrup for carrying a tie. Two men unload a tie from a truck and place it on the tie-stirrup, one man (one on each trolley) runs the tie into the car, the track having a slight down grade, and one man (one at each end of the car)

assists in unloading and piling. The man then takes the trolley off the track and carries it back to the loader. Thus with a gang of 6 men as much work is done as with 10 men unaided by this device. A gang of 6 men loaded 3,325 large creosoted hewn ties in 9 hrs., no effort being made to make a record. When timed they unloaded a truck of 30 ties into the car in 2 mins. Creosoted ties weigh 200 to 250 lbs. each, and as one man by using a trolley can easily transport them it is evident that much labor is saved. I would suggest the use of a similar device for handling sacks of cement (2 sacks on a double stirrup), for handling brick, two-man stone, etc.

Cost of Burnettizing Timber and Ties.*—The following data relate to the cost of treating timber by the zinc chloride process, known as burnettizing. The extremely low cost of preserving timber in this manner will doubtless astonish many of our readers who are more familiar with the relatively high cost of creosoting. In this article we shall show that burnettizing costs about \$2.50 per 1,000 ft. B. M., or 3 cts. per cu. ft.; and in a subsequent article we shall give similarly detailed figures showing a cost of \$16 per M., or 16 cts. per cu. ft. for creosoting.

The plant has a capacity of 2,500 ties per day, and the following is the average cost of a year's work:

	Cts. per cu. ft.
0.3 lb. zinc chloride, at 3.8 cts.....	1.14
Fuel, at \$3.50 per ton.....	0.25
Oil, etc.	0.06
Current repairs	0.10
Switching engines, etc.....	0.10
Depreciation, 10% of \$75,000 plant divided by 2,500,000 cu. ft.....	0.30
Labor	1.05
Total per cu. ft.....	3.00

The ties were 7 x 9 ins. by 8 ft., containing 3.5 cu. ft. each, hence the cost per tie and per 1,000 ft. B. M. was as follows:

	Cts. per tie.	Per M ft. B. M.
Zinc chloride, at 3.8 cts. lb.....	4.00	\$0.95
Fuel	0.87	0.21
Oil, etc.	0.21	0.05
Current repairs	0.35	0.08
Switching engines, etc.....	0.35	0.08
Depreciation	1.05	0.25
Labor	3.67	0.88
Total	10.50	\$2.50

The amount of zinc chloride per cubic foot is somewhat less than is commonly used, being 0.3 lb. as compared with 0.4 to 0.5 lb. per cu. ft.

Cost of Burnettizing Ties on the S. P. Ry.—On the Southern Pacific Ry., in 1893, the cost of burnettizing ties was 9½ to 12 cts.

**Engineering-Contracting*, July 3, 1907.

per tie 6 x 8 in. x 8 ft. About 221,000 "sap" ties were treated during the year, these ties being purchased at the mills in Texas for 22 cts. each.

Cost of Creosoting Piles and Ties.*—In our issue of July 3 we gave the itemized cost of burnettizing ties, the total cost being \$2.50 per 1,000 ft. B. M., or 10½ cts. per tie of 7 x 9 in. x 8 ft. The following data relate to the cost of creosoting ties and piles. Creosoting is a much more expensive process, but the burnettizing treatment is of no use where timber is constantly exposed to the action of water, as is the case wherever piles are used. Water leaches out the zinc chloride in a comparatively small time whenever the timber is constantly submerged, and, even where it is exposed to frequent rains the zinc chloride is dissolved little by little until there is no longer enough left in the timber to protect it from the fungus of decay. Could someone devise a method of filling the outer pores of burnettized wood with some waterproof compound it would be possible to use the zinc chloride for preserving the body of timber that is exposed to water. For example, it might be practicable to treat the surface of burnettized timber with the Sylvester process which has been so successfully used in waterproofing masonry, namely, by coating with soft soap and alum in such a manner as to fill the pores with a curd like precipitate. Indeed, it might be practicable to treat timber, first with zinc chloride and subsequently with creosote, so that the creosote would form the outer protective shell.

The following costs represent the average of a year's work in a plant having a capacity of 500,000 cu. ft., or 6,000,000 ft. B. M. per annum.

The cost of treating the timber was as follows, per cu. ft.:

	Cts. per cu. ft.
1.05 gal. creosote, at 11.5 cts.....	12.08
Fuel (\$3.50 per ton) and other supplies.....	1.82
Labor	3.75
Depreciation, maintenance and repairs.....	1.50
Total	19.15

This is equivalent to \$19 per 1,000 ft. B. M., which is more than six times as expensive as burnettizing.

A 7 x 9-in. x 8-ft. tie contains 3.5 cu. ft., hence the cost of creosoting each tie was \$7 cts., as compared with 10½ cts. by the zinc chloride process (burnettizing).

About 300,000 lin. ft. of piles were creosoted, and it was found that the piles average 1.11 cu. ft. of timber per lin. ft. of pile. Hence the cost of creosoting was 21½ cts. per lin. ft. of pile.

In analyzing the above costs per cu. ft. it will be noted that the item of depreciation and maintenance is 1.5 cts. per cu. ft., which is equivalent to \$1.80 per M. This item is based on an allowance of 10% per annum for depreciation of a \$75,000 plant, plus current repairs and insurance.

**Engineering-Contracting*, Aug. 7, 1907.

See the section on Timber in this book for further data on creosoting.

Cost of Treating Ties With Zinc Chloride and Creosote, Galesburg, Ill.*—The Chicago, Burlington & Quincy Ry. has built a plant for treating ties at Galesburg, Ill. The plant is situated on a tract of 30 acres with a space for tracks having a capacity of 2,000,000 ties, although at present there are tracks for a storage of only 1,000,000. For fire protection in the yard, hydrants are spaced 300 ft. apart, being supplied with water from a 100,000-gal. storage tank, fed by a well 1,300 ft. deep. The tracks in the yard are laid with three rails, as narrow gage cars are used to deliver the ties to the retorts.

The plant was located at Galesburg as it is the connecting point of the Burlington lines with the south, the principal source of the supply, and on this part of the system there are always available stock cars for the shipment of the treated ties. Box cars cannot be used for this purpose on account of the odor which is retained in the cars when loaded with creosoted timber.

The main building is 152 x 115 ft., divided into three rooms, one containing three retorts, another the engines and tanks, the third being the boiler room. There is also a test room, fitted up for treating four ties. The building is of reinforced concrete throughout. The window sashes are of metal, glazed with wire glass, while the doors are all covered with sheet metal.

The retort room is the full length of the building and 38 ft. wide, the retorts being 122 ft. long and 6 ft. in diameter, made of $\frac{3}{4}$ -in. steel, furnished by the Allis-Chalmers Co. Each has a capacity of 650 ties, while the plant treats 6,000 ties in 24 hrs.

There are three 150-hp. boilers, one being for emergencies. There is no chimney, induced draft system being used. The engine room, 30 x 115 ft., contains an Ingersoll-Rand compressor, with a capacity of 525 cu. ft. of free air per min., a Knowles fire pump, three Knowles pressure pumps, one Knowles oil pump and one Battle Creek vacuum pump. There is also a small electric light plant in this room.

The tank room, 39 x 50 ft., contains a 25,000-gal. steel working tank and a 100,000-gal. steel mixing tank for creosote. On the outside, close to the main building, are the storage and measuring tanks, one 500,000-gal. steel tank for creosote storage and two 5,000-gal. steel tanks for measuring creosote, two 50,000-gal. wooden tanks for zinc chloride and one 25,000-gal. iron storage tank for zinc chloride. The two steel outside tanks are arranged for heating with steam coils.

The plant is arranged with its pipe connections between pumps, tanks and retorts, so that the straight zinc chloride process, of the two, known as the Card process, may be used on one retort or on all

**Engineering-Contracting*, Sept. 2, 1906, an abstract of an article in *The Railway Age*.

three. In the Card process, which is a modification of the Rutger, the zinc chloride and creosote are continuously agitated under pressure by centrifugal pumps, and ordinary coal tar creosote can be used. Each retort is connected with an electrically driven centrifugal pump, which forces the liquid in at the bottom and exhausts it from the top of the retort. The vacuum in retorts is obtained by a Baragwauth barometric condenser, with an auxiliary air pump $6\frac{1}{2} \times 12 \times 12$ ins. having a connection with the air chamber of the condenser. The condensing pipes are placed on the roof of the engine room.

The Rutger process has been used in Germany, but it requires a creosote having special qualities and is expensive. In the Allardyce process the zinc chloride is put in first and then the creosote, while the Ruping process aims to reduce the expense for creosote by first filling the wood cells with compressed air and then coating them with creosote.

Seasoned ties are treated directly, but if green they are first steamed under pressure of 5 to 20 lbs. from 1 to 2 hrs. The sap is blown off every 15 to 30 mins. With the Card process a vacuum of 27 to 28 ins. is held on the retort for an hour, and, with the vacuum still on, the mixture of zinc chloride and creosote is run in by gravity, entirely filling the retort, and requires about 12,000 gals. The liquid is heated to 180° F., and at this temperature the two ingredients do not separate as rapidly as in a cold solution. The centrifugal pumps are then started and the liquid is circulated at the rate of 2,500 gals. per min. and the whole charge is changed every 7 or 8 mins. At the same time the pressure pumps are started and pressure gradually increased to 150 lbs. and held at that for 2 to 4 hrs., or until a sufficient amount of the liquid is absorbed by the timber.

The pressure pumps are connected to the 5,000-gal. measuring tanks which have gauges operated by floats, and in this way the volume of liquid forced into the timber is known. When the gauges show a sufficient amount the pressure is released and the remaining liquid is forced back into the mixing tank. Then a vacuum of 24 to 28 ins. is created and held for an hour, taking out all surplus liquid into the underground tanks, where it is allowed to settle and then returned to the mixing tank. This last treatment is for the purpose of removing the surplus creosote remaining on the surface of the ties, so they can be handled comfortably, and 500 gals. saved from each retort.

The retort door is then opened and the cars withdrawn by wire cable operated by electric motor and switched to the platform, where they are loaded directly for shipment. Each tie is marked with a short thick nail having the year of treatment on its head. The ties are loaded by the Anzler loader at a cost of 25 cts. per tram.

An approximate cost of the new plant is as follows:

Land	\$ 28,000
Tracks	50,000
Sewers	5,000
Well	6,000
Platform	3,000
Building	30,000
Three retorts	30,000
Tanks of all kinds.....	10,000
Pipes and valves and labor.....	20,000
Pumps	6,000
Boiler and settings.....	5,000
Electric light plant.....	3,000
Mundy hoists	2,500
	<hr/>
	\$198,500

Thirty men are employed in the offices and plant, there being a chief engineer and chemist, 2 engineers and 2 assistant engineers for day and night, 3 sub-foremen and 2 motormen, besides the laborers.

The liquid used is a mixture of 17% creosote and 83% zinc chloride solution, the latter containing 3% chloride and the rest water. The creosote has a specific gravity of 1.045 and contains about 35% naphthaline and 5% tar acid. The cost of creosote is 6½ to 7 cts. per gal.

The cost of treating a pine tie is estimated as follows:

	Per cu. ft.	Per tie . (\$ cu. ft.)
0.5 lb. dry zinc chloride, at 4cts.....	\$0.020	\$0.060
0.8 lb. creosote, at 3 cts.....	0.024	0.072
Labor, fuel, supplies and supt.....	0.013	0.040
Interest and depreciation.....	0.005	0.15
	<hr/>	<hr/>
Total	\$0.062	\$0.187

This figure is the cost during the winter months. The cost is less in warm weather—probably as low as 16 cts. About 46% of the ties treated at this plant are red oaks, and 35% yellow pine, the rest being gum, elm, beech, birch, etc.

The plant was designed under the supervision of T. E. Calvert, chief engineer, and F. J. Creiger, who now has charge of the plant.

It will be noted that at 6.2 cts. per cu. ft., the cost of treatment is equivalent to \$5.17 per 1,000 ft. B. M.

Cost of Treating Ties and Their Life.—In 1885 the A., T. & S. F. Ry. began treating ties by the zinc-tannin, or Wellhouse, process. Up to 1901, its cost of treating some 4,000,000 ties is said to have been 15 to 18 cts. per tie.

New Mexico mountain pine ties having a life of 4 yrs. when untreated have a life of 10½ to 11 yrs. when treated.

In 1888 the Chicago, Rock Island & Pacific Ry. contracted to have ties treated for 16 cts. per tie.

Some 4,750,000 hemlock and tamarack ties had been treated up to 1901, and the average life of these ties has been 10½ to 11½ yrs., depending on location.

In 1887 the Southern Pacific Ry. began burnettizing ties (zinc chloride process) without subsequent treatment. Up to 1901 it had treated 2,500,000 pine ties, which last 4 yrs. when untreated. The life of the treated ties was 7 yrs. where the rainfall was heavy (Glidden Division) to more than 9 yrs. where the rainfall was light (Del Rio Division). The average of all was 8½ yrs. life.

Not including interest or depreciation of plant, the cost of treatment was only 6.44 cts. per tie, in 1898.

About 0.24 lb. dry zinc chloride was used per cu. ft. of timber, or half the standard used in Europe.

Life of Treated Ties.—The records of treated pine ties taken out of the A., T. & St. P., showed the following averages:

	Life, yrs.
1897.....	10.18
1898.....	10.56
1899.....	10.61
1900.....	10.78
1901.....	10.68
1902.....	10.76

These ties were treated with the two-injection Wellhouse process. These figures relate only to the ties removed on account of rot.

Life of Ties.—For the fiscal year ending June 30, 1901, seven railways reported that untreated oak ties (white, post, burr, etc.) were in use on the following mileage:

	Miles of main line.	Miles of all track.
Chicago and Northwestern (Madison Div.)..	614	764
Illinois Central (Elgin Div.).....	286	321
Illinois Central (Springfield Div.).....	454	553
Nashville, Chattanooga & St. Louis.....	1,195	1,414
Penn. Lines (Pittsburg Div.).....	442	594
Southern Ry. (Eastern Dist.).....	2,200	2,749
Southern Pacific (Atlantic System).....	2,107	2,697
Total	8,298	10,012

There were 17,471,116 oak ties in these tracks, and 2,147,584, or 12.3% more renewed during the year, which is equivalent to a life of about 8 yrs.

The average life of ties, as estimated by different railways, was as follows:

Railway.	Kind of tie	Life in Years.—	
		Main track.	Side track.
Chicago and Great Western.....	Oak	8	10
Chicago and Northwestern.....	"	7	10
Illinois Central	"	7	9
Nash., Chatta. & St. L.....	"	7	9
Norfolk & Western.....	White Oak	8.5	9.5
Pitta. & Lake Erie.....	"	8	10
Boston & Maine.....	Chestnut	8	12
Illinois Central (Louisiana)....	Cypress	9	13

The French State Railway gave the following as the life of creosoted ties:

	Life Years on		
	Main line.	Siding.	Total.
Creosoted pine	16	6	20
Creosoted oak	18	7	25
Creosoted beech	20	10	30

Estimated Life of Ties in 1894.—Bulletin No. 9 (1894) of the Forestry Division, U. S. Dept. of Agriculture, states that when there were 235,000 miles of track (all main, branch and side tracks) in the U. S., 76,000,000 ties were annually required for renewals. This is equivalent to 324 ties renewed per mile of all tracks. If there were 2,800 ties per mile, the life was 8.7 yrs. The estimate of 76,000,000 ties for renewals may be accurate, since the reports of the railways to the Interstate Commerce Commission give the number of ties used each year for renewals.

Due to the use of heavier rails than were common in 1894 (15 yrs. ago), the life of ties is greater now than then.

Life of Ties as Affected by Weight of Rail.—Mr. P. H. Dudley states that on the New York Central Ry., when 65-lb. rails were used, the life of a yellow pine tie was 8 or 9 yrs. Since the introduction of 100-lb. rails, the life has increased to 11½ yrs. The ties are no longer cut by the rails nor injured by the frequent tamping required with lighter rails. He states (in 1901) that not 5% of the ties are now removed for other causes than decay, whereas 40% of the ties under 65-lb. rails were taken out because of cutting under the rail and other injury. Eighteen ties used per 30-ft. rail length, or 3,168 per mile. The average tie renewals from 1890 to 1900, was 293 ties per mile, or 9¼%, for untreated ties of all kinds.

Spacing of Ties on Different Railways.—In 1901 the following was the spacing of ties on different railways:

	Ties per mile.	
	Main track.	Side track.
Baltimore & Ohio.....	2,856	2,650
Chicago & Great Western.....	3,000	2,800
Chicago & Northwestern.....	2,990	2,500
C., M. & St. P.....	3,000	2,640
C., C. & St. L.....	3,000	2,800
Illinois Central	2,168	2,640
Louisville & Nashville.....	2,816	2,112
Michigan Central	3,168	2,375
Nashville, Chatta. & St. L.....	2,900	2,640
New York Central.....	2,000	2,500
Norfolk & Western.....	2,816	2,600
Penn. Lines (Pittsburg Div.).....	2,816	2,388
Pittsburg & Lake Erie.....	2,640	2,640
Southern Pacific (Atlantic Syst.)...	2,816	2,664
Southern Ry. (Eastern Dist.).....	2,816	2,640
Wabash (Detroit Div.).....	2,900	2,800
Union Pacific (2,816 on branches)...	2,992	2,640

It is probably very close to an average to say that there are 2,900 ties per mile of main line and branches, and 2,640 per mile of sidetrack and yards, in the railways of the United States. Since there are 0.4 mile of sidetracks and yards per mile of main track

and branches the average of all tracks would then be 2,820 ties per mile of track.

Labor Cost of Renewing Ties.—The cost of distributing new ties, taking out old ties and laying new ones, and disposing of the old ties by burning, averaged as follows for the years 1904 and 1905 on one of the divisions of the Northern Pacific Ry. in Washington:

	Per new tie.
Distributing	\$0.028
Laying	0.110
Disposing of old tie.....	0.009
Total	\$0.147

Wages averaged \$1.45 per day for section men and \$2.00 per day for section foremen. The ties were laid on a gravel ballast.

Prices of Ties and Labor Cost of Renewals.—In 1901 the following was the cost of ties and of placing them in track on several typical railways:

Road.	Kind	Cost deliv. at track...	Cost loading on cars...	Cost per 100 miles haul.	Cost of dis-tributing...	Cost putting in track...	Total cost, cts.
So. Pacific	Redwood	32	1	1	1 1/2	10 1/2	52 1/2
Mich. Cent.	Oak	45	1 1/2	4 1/2	1	10	60
Wabash	Oak	40	1 1/2	5	1	10	55
N. Y. Cent.	Y. Pine	59	1 1/2	4	1	10	77 1/2
Louisville & N.	Y. Pine	45	1 1/2	15	61 1/2
Denver & R. I.	Red Spruce	32	1	1 1/2	1	1 1/2	37
Mo. Pacific	Oak	32	1 1/2	5	1 1/2	6 1/2	49 1/2
Lake Shore & M. S.	Oak	55	1 1/2	15	71 1/2
Union Pacific	Oak	56	..	1 1/2	1 1/2	10	71 1/2
Union Pacific	Wyo. Pine	40	..	2 1/2	2	11	57 1/2

Average Price of Ties in America.—The annual reports made by the different railways of America to the Interstate Commerce Commission contain statements of the number of ties used in renewals and of the average price paid for ties at the point of distribution. Unfortunately the reports made by the Interstate Commerce Commission contain none of these data. However, the reports give the total cost of tie renewals each year, which is approximately \$120 per mile of all track. If there are 2,800 ties per mile, and if 10% are renewed annually, then the average cost of ties is 46.4 cts. This does not include the cost of distributing and laying the ties. If 11% of the ties are renewed annually, the average cost of ties is 42.2 cts. per tie. It is reasonably certain that, including side tracks and yard tracks, tie renewals (untreated ties) average 10 to 11% per year for American railways, variations from this average depending on kind of wood, climate, weight of rail, etc.

Cost of Gravel Ballast.—A common amount of gravel ballast is 1,600 cu. yds. per mile of track, and rarely need the cost exceed 40 cts. per cu. yd., including the labor of putting the ballast under the ties and surfacing the track. A not unusual contract price is 27 cts.

per cu. yd. for loading ballast on flat cars with steam shovels, unloading with ballast plows, and putting under the ties, and surfacing of track. In addition to this the railway company must pay the cost of hauling the ballast—work train service—which should not exceed 17 cts. per cu. yd. even for a haul of 100 miles.

The following is a typical gang for loading, hauling and unloading

Ballast

<i>Steam Shovel.</i>		Per day.
1 foreman, \$150 per mo.....		\$ 6.00
1 engineman, \$125 per mo.....		4.30
1 cranesman, \$90 per mo.....		3.50
1 fireman, \$60 per mo.....		2.30
1 watchman, \$60 per mo.....		2.30
1 timekeeper, \$60 per mo.....		2.30
6 pit laborers, at \$2.00.....		12.00
6 laborers "throwing" pit tracks and repairing		12.00
Total		\$ 45.20
Repairs to steam shovel.....		8.00
Total steam shovel loading		\$ 53.20
<i>Hauling Ballast.</i>		
1 conductor	\$ 3.50	
2 brakemen, at \$2.50.....	5.00	
<i>Engine service on work train.</i>		
1 engineman	\$ 4.50	
1 fireman	2.50	
Coal and oil.....	8.50	
Engine rental and repairs.....	12.00	
		27.50
Engine service "spotting" cars.....		27.50
Rental and repairs, 40 flat cars, at \$0.50.....		20.00
Total hauling ballast		\$ 83.50
<i>Unloading and Distributing Ballast.</i>		
1 operator of unloading plow.....	\$ 3.00	
10 laborers, at \$2.00.....	20.00	
Coal and oil for unloader.....	4.00	
Rental and repairs of unloader.....	4.00	
Total unloading ballast		\$ 31.00
Grand total		\$167.70

When this crew is handling 800 cu. yds. of gravel per day the cost is:

	Per cu. yd.
	Cts.
Loading	6.7
Hauling	10.4
Unloading	3.9
	21.0

In addition to this, the labor cost of tamping ballast under ties and track surfacing is about 12 cts. per cu. yd.

It often happens that gravel pits must be stripped of overlying earth, that considerable grading is necessary for tracks into the pit, that the gravel is cemented and requires some blasting, and that "pit rent" must be paid for the gravel. All these items, however, will rarely amount to 7 cts. per cu. yd., so that the total

cost of the gravel in the track should rarely exceed 40 cts. per cu. yd.

Where traffic on a road is so congested that a ballast train cannot average more than 100 miles traveled per day, and where the load hauled is only 150 cu. yds. per train, it is evident that 5 trips of 10 miles and return will be required to haul 800 cu. yds., and to the figures above given must be added another train for each additional 10 miles of distance from the gravel pit to the dump. However, on long hauls it is obvious that much heavier train loads will ordinarily be used, thus keeping the cost down.

Cost of Gravel and Rock Ballasting Old Track.*—The following matter has been taken from the report of a committee read before the 1907 convention of the Roadmasters and Maintenance of Way Association: On a northern division of the Chicago & Northwestern Ry. the cost of ballasting one mile of track with gravel was \$1,020, figured on the basis that 3,400 cu. yds. of material would be used per mile. The gravel was unscreened and unwashed and was used just as it came from the pit. The gravel was placed for a 12-in. raise with standard gravel roadbed on the top of 11½-ft. slope 1½ to 1, and 16 ft. wide from bottom ballast line to ballast line. The itemized cost per cubic yard was as follows:

	Per cu. yd.
Cost of gravel loaded on cars at pit.....	\$0.079
Hauling and unloading, 50-mile haul.....	0.107
Ballasting	0.123
Total	\$0.309

On a division of the Lake Shore & Michigan Southern Ry. for the year 1906 the cost of ballasting with gravel was as follows:

	Per cu. yd.
Gravel, washing and loading.....	\$0.18
Hauling	0.07
Digging out old ballast.....	0.15
Unloading and placing in track.....	0.15
Total	\$0.55

For crushing limestone ¾ to 1½ ins. in size the cost was as follows:

	Per cu. yd.
Cost of stone.....	\$0.535
Digging out old ballast.....	0.150
Hauling, unloading and placing in track.....	0.400
Total	\$1.085

For ballasting with crushed stone on a division of the Atchafalaya, Topeka & Santa Fe Ry. the cost was as follows:

	Per cu. yd.
Crushed stone at crusher, loaded on cars.....	\$0.615
Haul, 50 miles.....	0.055
Labor (Mexican) inserting.....	0.330
Total	\$1.00

*Engineering-Contracting, Dec. 25, 1907.

For a 12-in. raise 3,400 cu. yds. of ballast are used per mile, making the cost \$3,400. The present standard on this road requires the ballast to be dressed level with the top of the ties for the full length of the tie and 6 in. beyond the ends of ties, making the top widths of the ballast 9 ft. and giving a slope of $1\frac{1}{4}$ to 1; this gives a roadbed 18 ft. wide from ballast line on one side to ballast line on the other side, with a 12-in. raise.

Cost of Gravel Ballasting.—About 30 miles of single track railroad were ballasted with gravel sufficient to raise the ties 8 in. Ties had 10-in. face, were $8\frac{1}{2}$ ft. long, and there were 18 ties to a 30-ft. rail. A $2\frac{1}{2}$ -yd. steam shovel was used to load flat cars. About 4 ft. of earth had to be stripped off the gravel pit. The gravel was hauled by two trains of 35 apron flat cars each, each car holding 6 to 7 cu. yds. Two locomotives were used to haul these trains and one locomotive in the pit to spot cars. The cars were unloaded with a plow, and it will be noticed that the damage to the cars caused by the plow was very high. The cost to the railway company per cubic yard of ballast in place was as follows:

	Cts. per cu. yd.
Pit rent	1 $\frac{1}{2}$
Loading, hauling and dumping.....	16 $\frac{1}{2}$
Repairs to cars.....	5
Shoveling and tamping ballast in track.....	8
Total per cu. yd.....	30
Common laborers were paid \$1.25 per 10 hrs.	

Cost of Cemented Gravel Ballast.*—There are two principal points in the territory east of Memphis where cementing gravel is worked for the purpose of supplying ballast to railroads; one at Iuka, Miss., on the Southern Ry., known as the Tishomingo Gravel Pit, owned and operated by the Tishomingo Gravel Co., of Memphis, Tenn., and one at Perryville, Tenn., on the Memphis & Paducah Division of the Nashville, Chattanooga & St. Louis Ry., owned and operated by the Perryville Gravel & Ballast Co., of Memphis, Tenn.

As the character of the gravel and the manner of working the two pits are somewhat different, they will be handled separately.

Tishomingo Gravel.—This is a water-worn gravel lying in a compact mass requiring blasting before it can be handled with a steam shovel. It is composed of 20% clay, 5% sand, and 75% gravel. This gravel as a rule is small and none of it large enough to require crushing to make it suitable for ballasting purposes. In order to get it in shape to load with steam shovel, it is loosened up by blasting. This is accomplished by digging a tunnel about 20 x 26 ins. in cross-section into the material a distance of about 26 ft., then turning at right angles for a distance of 10 ft. (see Fig. 8). This digging is done by a man lying down using a pick with a very short handle. The cost of digging these tunnels is 50 cts. per ft.

**Engineering-Contracting*, April 14, 1909.

The charge is placed in the extreme end of the tunnel and a portion of it refilled as shown on sketch. From 75 to 100 carloads of material is loosened up at each blast. This material is then loaded by steam shovel onto cars. The cost of this material is as follows:

	Per cu. yd.
Loading	\$0.09
Hauling	0.20
Unloading and distributing.....	0.07
Putting under ties and surfacing.....	0.11
Total	\$0.47

The advantages of its use are: Small cost, quick cementing qualities, holds track in line and surface well under fairly heavy traffic, does not churn, very little dust and has great resistance to erosion

Fig. 8.—Chamber Blast.

by water. Considered an excellent ballasting material. Has the disadvantage of growing prolific crops of weeds and grass, making it costly to keep clean.

Perryville Gravel.—This is an angular gravel lying in compact mass requiring blasting before it can be handled.

Large pockets of clay are encountered, making it preferable to load by hand in order to get the best material. It is composed of 10% clay and 90% gravel, with chemical analysis of 97% silica, 2.5% alumina and 0.5% iron. There is found in this pit considerable large stone, which has to be crushed before it is suitable for use. The cost of this gravel per yard is as follows:

	Per cu. yd.
F. o. b. cars at pit.....	\$0.27 1/2
Hauling, 100-mile train service.....	0.20
Unloading and distributing.....	0.04
Stripping, putting under and surfacing.....	0.20
Total	\$0.71 1/2

Cost of Washing Gravel.—A large gravel washing plant was built in 1906 by the Lake Shore & Michigan Southern Ry., at Pleasant Lake on the Ft. Wayne branch of the Lake Shore. The plant handles 3,000 cu. yds. of raw gravel daily. A 75-ton steam shovel with a $3\frac{1}{2}$ -yd. bucket loads dump cars, which are dumped into two hoppers that discharge upon two inclined conveyors (made by the Link-Belt Co.), having a capacity of 4,000 cu. yds. per 10-hr. day. The conveyors discharge upon a short flume (8 ft. long) where the gravel encounters the water. Thence the material passes over several fixed screens, all material larger than 3-in. being shunted to a gyratory rock crusher.

The washed gravel for ballast collects in hoppers whence it is drawn off into cars, and the sand (all material larger than $\frac{1}{8}$ -in.) collects in other hoppers, whence it is drawn off into cars.

The output for a typical day is as follows:

	Cu. yds.
Raw gravel	3,270
Washed gravel	1,335
Washed sand	1,650

The following is the crew required to operate the plant:

- 1 foreman.
- 1 clerk.
- 1 engineman at plant.
- 1 fireman at plant.
- 1 shopman.
- 1 carpenter.
- 2 men on two sand settlers.
- 4 men dumping gravel cars.
- 4 men keeping track clean at washer.
- 10 men repairing cars and calking ballast cars with hay.
- 2 locomotive crews delivering gravel.
- 2 locomotive crews removing washed gravel.
- 1 steam shovel crew
- 30 men in section gang.

The washing plant is driven by a 200-hp. Erie steam engine, but the driving load on the engine is only 132 hp., of which 105 hp. is required to operate the pump supplying the wash water. A 10-in. single-stage centrifugal turbine pump (Werthington), having a 2,400-gal. rating under a 90-ft. head, is used; but the pump is not called upon to deliver more than 1,650 gals.

The cost of the plant and land was as follows:

Plant for washing.....	\$25,000
Land	15,000
Grading	10,000
Bridge work	2,500
Miscellaneous	5,000
Track	36,000
Total	\$93,500

Assuming that the gravel pit will be exhausted in 5 years, we have the following annual and daily cost (300 days per year):

	Per year.	Per day.
Plant, 15% of \$25,000.....	\$ 3,750	\$13.75
Track, 10% of \$36,000.....	3,600	18.00
Grading, 20% of \$10,000.....	2,000	10.00
Bridging, 20% of \$2,500.....	500	2.50
Miscellaneous, 20% of \$5,000.....	1,000	5.00
Land, 20% of \$15,000.....	3,000	15.00
Total	\$13,850	\$69.25

Assuming that 3,000 cu. yds. of sand and gravel are produced daily, half of which is sand, for which there is no market, we have the following cost:

	Per day.	Per cu. yd. of gravel.
Operating expense	\$250.00	\$0.167
Plant and land depreciation.....	69.25	0.046
Plant interest (at 5% of \$93,500) ..	23.35	0.015
Total	\$352.60	\$0.228

This does not include the cost of stripping the gravel which was about 6½ cts. per cu. yd., making the total cost of this washed gravel nearly 30 cts. f. o. b. cars.

For description and drawings of this Pleasant Lake washing plant, and for hints on ballasting, see *Engineering-Contracting*, April 14, 1909.

Cost of Ballasting, Using Dump Cars.—The Goodwin steel car is largely used by contractors, and railway companies, for ballasting and for dumping earth and rock on standard gage tracks. Its dimensions are 36 ft. long, 9 ft. ¼ in. height above rails, and it weighs 47,500 lbs. Its capacity is 40 cu. yds., or 80,000 lbs. A train of cars can be dumped at one time all together, or one at a time, by one man operating a compressed air valve, or they can be dumped by hand. The car is so designed that its load may be placed between the rails; on either side of the track, or on both sides, or in any combination of ways desired. In grading and ballasting 22 miles of track with 30,000 cu. yds. of gravel, during the winter of 1904-5, an average train of 8 40-cu. yd. Goodwin cars was used, the average haul being 14½ miles. The gravel came from the pit quite wet, but required little or no spreading as plows and scrapers are not needed when these cars are used.

Mr W. B. Stimson, Superintendent Grand Rapids & Indiana Ry., gives the following data on the loading and hauling of gravel for ballast:

Rodger ballast cars were used, working two trains of 25 cars per train. Sixteen miles of track were ballasted with 1,039 carloads, or 26,800 cu. yds. of gravel, or 1,300 cu. yds. per mile, the average haul being 7 miles. The cost was as follows for the 16 miles:

	Total.	Per day.
Two train crews, 12 days each.....	\$ 175.60	\$14.58
Locomotives, enginemen and watchmen.	199.25	16.60
Fuel for locomotives.....	254.10	21.17
Telegraph operator	15.50	1.28
Pit foreman	28.84	2.40
Pitmen	100.35	8.36
Steam shovel, including rent of shovel, fuel and wages.....	323.52	26.96
Total, at 5.3 cts. per cu. yd.....	\$1,096.56	\$91.35

In addition to this it cost 6.7 cts. per cu. yd. to spread and tamp the gravel in the track, each laborer averaging 75 ft. of track per day. Including in the expense of 5.3 cts. per cu. yd., is the cost of moving the two trains and the steam shovel 166 miles to the pit, and half a day's time setting up the shovel and getting ready to work; so that the actual working time of the shovel was only 10½ days, making an average of 2,000 cu. yds. loaded per day of 12 hrs. The depth of the face at which the shovel worked was only 8 ft. The above is an exceedingly low cost.

The Rodger ballast car is 8 ft. 9 ins. x 34 ft. over sills, weighs 28,000 lbs. and its capacity is 60,000 lbs., or 20 cu. yds. of gravel heaped measure. The car is hopper bottomed, with plows and scrapers for spreading the ballast. One car is dumped at a time and fills about 80 ft. of track.

Cost of Rock Ballast.—The Railroad Gazette, Nov. 16, 1906, p. 438, gives the following cost of re-ballasting an Eastern railway:

	Per cu. yd.
Rock on cars at Rockland Lake.....	\$0.575
Floatage from Rockland Lake.....	0.086
Distribution by train (Rodger cars and ballast plow)	0.035
Labor putting in track.....	0.058
Total	\$0.754

This does not include cost of preparing the old track, forking up old ballast, lifting track, etc.

It is estimated that \$0.15 per cu. yd. would cover the added cost of putting rock ballast in a new track, including cost of lifting track, tamping, surfacing, etc.

Prices of Frogs and Crossings, Etc.—The prices used in estimating the cost of frogs, etc., on the New York Central, in 1902, were:

No.	Wt. of Rail, Lbs.	Description.	Price.
6	80	Rigid, Bolted	\$27.00
10	80	Rigid, Bolted	32.00
10	65	Spring R.	43.50
8	60	Rigid, Bolted	23.00
8	65	Rigid, Bolted	24.00
8	75	Rigid, Bolted	28.50
Type A	80	Crossing Bolted	\$35.00 to \$65.00
10	75	Spring R. Bolted	51.00
7	80	Rigid, Bolted	27.50
10	80 (5 1/4")	Spring R.	49.25
10	67 (4 1/2")	Spring R.	44.50
18	80 (5 1/4")	Rigid, Bolted	45.00 to 70.00
Rail braces, 3.32 lbs. each, each.....			\$.16%
Rail joints (80-lb. rail), Weber, insulated.....			5.25
Rail joints, Atlas, com.....			3.75
Rail joints, 22-in. for 80-lb. rail.....			2.50
Replacers, Little Giant.....			15.00
Rail bender, roller.....			142.00
Rail chairs, cast, per 100 lbs.....			2.48
Rail chairs, weights:			
4 ins. high, 19.5 lbs.			
3 ins. high, 18.6 lbs.			
Switch stand, Ramapo, low.....			10.00
Smoke jack in place.....			40.00
Track drill.....			10.00
Track jack.....			2.00

Cost of Track Scales.—On the N. Y. Central a 100-ton track scales, 42 ft. long, cost as follows, in 1902:

Scales and materials.....	\$1,760
Labor.....	640
Total.....	\$2,400
8.7 tons rails (relays), at \$20.....	174
15 ties, at \$0.60.....	9
Miscellaneous material.....	150
Labor laying track, etc.....	70
Grand total.....	\$2,803

No piles were used in foundation.

The cost of 50-ton track scales, 42 ft. long, on the Northern Pacific, in 1899, averaged as follows:

Scales, delivered.....	\$ 530
Other materials.....	170
Labor (\$175 to \$300).....	250
Total.....	\$1,000

The cost of 80-ton track scales, 50 ft. long, in 1905, was as follows:

Scales and materials.....	\$1,250
Labor (\$500 to \$700).....	650
Total.....	\$1,900

Cost of Water Tanks.—On the Chicago & Northwestern, in 1896, the following was the cost of four different 50,000-gal. tanks, 16 x 24 ft., on 24-ft. posts:

TANK No. 1.**Material:**

Water tank, including hoops, etc.....	\$ 275
Two 8-in. standpipe.....	380
540 ft. 8-in. pipe, valves, etc.....	316
1 bbl. pitch and 1 bbl. oakum.....	7
Posts, caps and braces.....	209
Stone, cement, etc., for foundation.....	309
108 ft. 4-in. gas pipe.....	22
Total material	\$1,517

Labor:

Building tank	\$ 203
Building masonry foundation.....	209
Painting tank, 2 coats.....	26
Laying pipe and setting standpipes.....	178
Total labor	\$ 616
Grand total	\$2,133

TANK No. 2.**Material:**

Tank, and posts, braces and caps.....	\$ 304
One 8-in. standpipe.....	190
Two 8-in. gate valves.....	45
608 lbs. lead	21
650 ft. 8-in. cast-iron pipe.....	255
Lumber for well, pump house and standpipe foundation	28
30 ft. 4-in. gas pipe... ..	16
Paint	20
Stone, cement, etc.....	289
Total material	\$1,168

Labor:

Building tank	\$ 201
Building foundation	120
Laying pipe	199
Painting tank, 2 coats.....	35
* Digging well (16 x 18) and walling it up.....	290
Total labor	\$ 845
Grand total	\$2,008

TANK No. 3.**Material:**

Tank	\$ 275
One 10-in. standpipe.....	228
90 ft. 10-in. cast-iron pipe.....	72
Fittings for pipe and standpipe.....	66
Foundation for tank and standpipe.....	160
Paint	13
Total material	\$ 780

(Posts, etc., seem to have been omitted.)

Labor:

Building tank	\$ 238
Building foundation	133
Laying pipe	93
Painting, 2 coats	81
Total labor	\$ 595
Grand total	\$1,275

TANK NO. 4.**Material:**

Tank	\$ 304
10-in. standpipe	225
60 ft. 12-in. cast-iron pipe	72
Valves, elbows, etc.	65
2,586 lbs. lead, at 8 $\frac{3}{4}$ cts.	87
250 pieces 6-in. cast-iron pipe	1,230
Paint	20
Material for standpipe	21
Material for tank	129
Total material	\$2,153

Labor:

Building tank	\$ 238
Laying 3,000 ft. pipe, at 30 cts.	600
Building foundation of tank	112
Building foundation of standpipe	18
Painting, 2 coats	29
Total labor	\$ 987
Grand total	\$3,140

The cost of a 16 x 24-ft. tank, on the C., R. I. & P., in 1896, was:

Tank with 12 hoops	\$275
Indicator	6
Set 7-in. fixtures	68
12 iron post caps	24
Rail joists, at \$5 per ton	19
Substructures (incl. frost proofg.)	198
Paint	16
Foundation stone	69
Labor erecting tank	165
Labor painting tank	24
Labor on foundation	116
Total	\$978

On the Lehigh Valley Ry., in 1896, a 20-ft. tank cost as follows:

2,720 lbs. wrought-iron hoops, at 3 cts.	\$ 82
4,560 ft. B. M. of 3-in. cypress for staves and bottom, at \$28	128
700 ft. B. M. yel. pine (1 x 3) for false bottom, at \$20	38
6,000 ft. B. M. white pine, at \$30	180
Nails, door, ladder, etc.	30
66 cu. yds. masonry foundation, at \$5.00	330
Lead, etc.	35
Labor erecting tank	175
Total	\$938

On the Northern Pacific, from 1890 to 1900, the average cost of 25 tanks, 16 x 24 ft., was as follows:

Materials	\$ 800
Labor	800
Total	\$1,700

In no case does this include pump, pump house, well, etc., but it does include pipe, foundation, etc.

The cost of a typical water tank on the Erie Ry., in 1901, was as follows for a 50,000-gal., 16 x 24-ft. tank:

Tank and Substructure:

16 x 24-ft. pine tub.....	\$ 275
30,270 lbs. steel trestle, at \$2.25.....	832
49 ft. iron ladder.....	13
9 squares slate for roof.....	27
9 squares tar paper.....	2
40 lbs. yellow metal slate nails.....	7
128 ft. galv. ridge roll.....	4
Pine	80
Nails, etc.	10
14 gals. paint	16
63 bbls. cement	86
30 cu. yds. crushed stone.....	12
31 cu. yds. sand	15
9,000 brick	62
Mason labor	229
Carpenter labor	187
Total	\$1,869

Plumbing:

Standpipe, 10-in., complete.....	\$ 225
10.75 tons 10-in. cast-iron pipe.....	227
1 length (12 ft.) 10-in. flanged pipe.....	17
3 elbows (10-in.) and 1 sleeve (10-in.).....	25
552 lbs. lead	24
120 ft. galv. pipe (3-in.).....	47
1 Worthington meter (3-in.).....	78
1 gate valve (3-in.).....	4
1 angle valve (2-in.).....	2
70 ft. sewer pipe (4-in.).....	2
1 iron grating for drain pit.....	4
1 galv. iron float, beam and chain.....	4
4 pr. pipe flanges (3-in.), etc.....	6
8 nipples (3-in.), 4 elbows and 1 tee.....	2
Labor of plumbers.....	152

Total plumbing \$ 840

Grand total \$2,709

Cost of Track Tank.—The form of track tank shown in Fig. 9, 1,200 ft. long, on the B. & O. R. R., cost as follows, in 1890:

Repairing roadbed	\$ 1,094
Labor placing trough and pipe.....	2,135
Trough, including shop work.....	4,159
Cross-ties, pipe and other material	2,936
Hauling	61
Total	\$10,385

The trough was of steel 3/16 in. thick, made in 30-ft. sections.

The above cost includes 75 ft. of 8-in. cast-iron pipe and two standpipes for use of freight engines.

The cost of operating such a track tank was as follows per month:

Two pumpmen, at \$45.00.....	\$ 90.00
15 tons coal, at \$1.50.....	22.50
Ordinary repairs	20.00
Total	\$132.50

Examples of Practice in Turntable Construction, With Some Data on Costs.*—The following text consists of a series of letters discussing seven subjects suggested by a committee as follows:

(1) Proper length, allowing for probable future increase in length of locomotives. (2) Plate girder tables, and cost. (3) Cast-iron tables, and cost. (4) Gallow's frame tables, and cost. (5) Other designs, and cost. (6) Foundation, circle wall, paving if any and pit drainage. (7) Power for operation; electricity, air and other power.

Fig. 9.—Track Tank.

J. P. Carty, Boston & Maine R. R.—Anticipating the probable length of a turntable required for future locomotive service, is rather an uncertain problem just at this period. However, it is the opinion of many that, on the division where I am located, the lately purchased steam locomotives have apparently reached their economical limits in both length and weight, provided the class of traffic remains similar to that which is now being handled.

The largest engines on our division are turned easily on turntables 70 ft. long. This is now our standard length, and as far as we are able to predict, will answer for future requirements.

The steel work in these tables cost approximately \$2,500 on board cars delivered to our road by the contracting bridge company. There is nothing unusual about the design. However, I will mention that we specify that four cast steel end wheels shall be furnished on each end of table and the center pivot bearing shall be of the disc pattern; meaning that the table turns on a composition disc on top of the center cast steel pivot casting, instead of on the familiar roller bearing.

**Engineering-Contracting*, Oct. 27, 1909.

Our turntable center foundations have, of late, been made of concrete, being 10 x 10 ft. on bottom and bearing on piles when there is doubt about the earth being sufficiently solid to carry the maximum load on this area without settling. The bottom course of concrete is generally 2 ft. in depth. The foundation is then stepped 7½ ft. square by 2 ft. thick, and a granite cap 6 ft. square by 2 ft. in depth is placed on top to receive the cast steel center pedestal.

There are 330 cu. yds. of masonry in our 70-ft. turntable pits. The whole outfit, including turning motor, costs us between \$6,000 and \$7,000. Figures vary for different locations, depending upon whether or not we are obliged to drive piles, provide expensive drainage, etc.

Practically all of these new outfits have been put in where older and smaller tables were installed and as the older tables were kept in service just as long as possible so as to avoid delays to engines, our work has always been made more expensive than if new tables were constructed where we would not be handicapped by keeping the old table in use.

We use gasoline power turning device.

The floors of the turntable pits are covered with a coal-tar concrete paving, about two and one-half inches thick, somewhat similar to that which is used extensively in small cities and towns in New England for sidewalk surfaces. This gives a fairly hard and elastic surface, and does not crack when soil underneath heaves with frost, and is comparatively smooth, so that it is easily kept clean and snow may be removed from pit without much trouble. The cost is about 50 cts. per sq. yd.

A. H. Beard, Philadelphia & Reading Ry.—The cost of our plate girder standard 75-ft. table in place ready for the track rails is \$7,785.00, as follows:

Masonry	\$2,500.00
Miscellaneous	500.00
Table	4,785.00
	<hr/>
	\$7,785.00

A 65-ft. plate girder table has been in service at the roundhouse at Reading since 1897. This was manufactured by the Pottstown Bridge Co. Engines of all classes are turned on this table, the number turned every 24 hrs. (although the table is short for some engines) is 75 to 80. The cost of this table in place was \$5,825. This table at present is operated by an 8-hp. gasoline engine, manufactured by the Williamsport Gasoline Engine Co., the cost of same in place was a fraction over \$1,000, and costs for operating about \$165 per month, this includes labor, oil, gasoline and repairs; we are now arranging to install an electric motor on the same table to replace the gasoline engine.

E. E. Schall, Lehigh Valley R. R.—Our 80-ft. turntable is constructed as follows: Deck plate girders 6 ft. 6¼ in. deep at center and 2 ft. 8¼ in. at ends, spaced 6 ft. c. to c., conical wheel center bearings with live ring, built for a moving load of Cooper's

El. 50 engines or 4,500 lbs. per lin. ft. of table. Cost about \$3,200 delivered f. o. b. cars within 200 miles of bridge shop.

The center foundations and circular rim walls are generally of concrete, the circular rail resting on short sawed ties. The top of rim is covered by a white oak timber coping to act as a cushion with rail tie-plated. The pit is paved with concrete about 4 ins. thick, and provided with drainage. For outlying districts, and tables not used extensively, the rim wall is at times omitted, using only a segmental wall at entrance and run-off of table, using ballast under the ties of circular rail.

For operation we have in use electric motors, gasoline engine motors and air motors; all are giving satisfaction. When electric power is at hand, it is the most suitable power to use; when electric current must be purchased from other parties or when none is available, gasoline engine motors of from 8 to 10 hp. will prove very satisfactory. The air motor will also prove efficient if properly installed and arranged to take proper adhesion on circular rail, obtaining a sufficient supply of air from locomotives to be turned, unless the air can be taken from a compressor near by. The air motor will not turn as many engines in a given time as either of the other two kinds, on account of the time required in making couplings, but for outlying districts it is the best motor attachment available at this time. The cost of installing one of the motors ranges from \$900 to \$1,200.

A. A. Wolf, Chicago, Milwaukee & St. Paul Ry.—We use 35-ft. turntables on mountain division where the heaviest power is used, and 75-ft. tables on other main line divisions. We have three types of the plate girder tables, which we distinguish as through, semi-through and deck. The reason for these various designs is occasioned by the difficulty in many places of getting drainage from the pit to a sufficient depth to accommodate a deck table. These plate girder tables cost from \$6,000 to \$8,500, varying somewhat with local conditions, pertaining to the nature of foundations, etc. The labor amounts to from 35 to 40% of the total cost.

For plate girder tables, we use a concrete center pier, circle wall and circle rail foundation; the circle wall and foundation for circle rail being of monolithic construction. Piles are always used under center foundation, except at places where solid ledge rock is found. Piling is used under circle wall except where rock or other firm soil is found. We do not make it a practice to pave the pits. Drainage is provided by means of connection to roundhouse sewer or to low adjacent ground, according to local conditions.

We use gasoline and electric motors only for power; the electric motor, in our estimation, furnishes the ideal power for turntable operation where it can be procured without excessive cost. At several of our division points we have our own generators and consequently the current required for operating turntable costs but very little.

J. O. Walker, Nashville, Chattanooga & St. Louis Ry.—Our standard length is 70 ft. Plate girder tables cost with ties, latches, etc.,

in place, \$3,200. Masonry and foundations \$2,000. The cost of the masonry is extremely variable, however.

W. T. Main, Chicago & North Western Ry.—Turntables newly installed in the future should be 80 ft. in length. A 70-ft. King Bridge Co., deck plate girder turntable installed at Chicago Ave., in 1907, cost as follows:

Material	\$2,570.46
Labor	2,262.00
Total	\$4,832.46

This table replaced an old 60-ft. deck plate girder and was installed under continuous traffic except for two days while new concrete center pier was allowed to set. Over 400 engines were turned every 24 hrs. on old table during construction of new circle wall which will give some idea of conditions under which work was done and reason for high cost. Table is operated by 10-hp. electric motor which was used on an old table but furnished with new frame. A 70-ft. King Bridge Co., deck plate girder turntable installed in 1907 cost as follows:

Material	\$2,890.00
Labor	2,262.00
Total	\$5,152.00

This table replaced an old 60-ft. Lassig plate girder and was installed under traffic in same manner as the one before mentioned. About \$500 of the cost was due to renewal of radial tracks. The circle wall was built of concrete and the center pier of concrete, reinforced with scrap rails in order to spread the load over old masonry foundation. The table is operated by 10-hp. Pilling air motor and has six reservoirs under runways, the air being furnished by air compressor.

A 60-ft. Stroebel deck plate girder table installed at Chicago Ave., in 1899, on old masonry wall and new center pier, cost \$2,500. A 60-ft. Greenleaf cast-iron table installed at Milwaukee, 1899, including new center pier, cost \$3,100; the table alone cost \$1,160. A 60-ft. gallows frame turntable installed at Evanston in 1896 with timber circle wall and center pier cost \$983.

Circle walls should preferably be built of concrete except when table is renewed under traffic, where rubble masonry can be used to better advantage while working in cramped space. Center pier may require pile foundation unless subsoil is good, where a spread foundation of concrete or masonry 12 ft. square will serve. The advantage of paving in pit will hardly justify the additional expense though it is easier to keep pit clean when paved and helps the drainage. The best drainage possible should always be secured. Circle walls should have an offset at one point to allow of examination and repairs to end rollers and boxes, particularly where table has rollers between girders. Masonry circle rail seat should be extended at two points, diametrically opposite, to afford support for jacks for raising table and examining center. This saves placing cribbing

on soft ground when using jacks and renders the operation much safer.

Would recommend the use of electric motor for operating table wherever possible and where service demands the quick handling of engines; second choice, gasoline engine; third choice, air motor. The latter gives excellent service, where there is plenty of time for handling engines and where there is sufficient supply of compressed air which can be piped to reservoirs, but it is slow in operation where engine to be turned must supply the air.

A. O. Cunningham, Wabash R. R.—No table less than 75 ft. should be used. Deck tables of this length cost \$2,800. The foundation of circular wall and paving should always be of concrete; pit should be well drained; the cost of this for 75-ft. deck table would be \$3,700.

Electricity is the ideal power for operating a table. If this cannot be obtained a gasoline engine may be employed of about 6 hp. The cost of the electrical equipment would be \$1,150, and for the gasoline engine equipment \$1,000.

W. H. Moore, New York Haven & Hartford R. R.—The standard length for turntables on our road is 75 ft., but we build some tables 80 ft. long. The approximate average cost for a 75-ft. deck plate girder turntable is about \$3,500, and for a half through plate girder turntable about \$5,750. The cost of foundation of the circular wall, etc., varies so much, depending on the nature of the ground, that it would be hardly proper to name any average. I may say, however, that for a concrete pit with granolithic floor and granite center stone, in a location where there was good firm sand requiring no piles and where drainage could be cheaply taken care of, the total cost is about \$3,800. For power operation we use mostly gasoline motors; some air motors, and electric motors where current can be conveniently obtained. The cost of power installation averages about \$1,000.

G. Aldrich, New York, New Haven & Hartford R. R.—For the requirements of modern engines, 75-ft. minimum; 80-ft. recommend; 75-ft. deck plate girder, erected complete \$2,800, base of rail on table to top of center pier, 4 ft. 4 ins.; base of rail on table to top of circular rail, 4 ft. 8 ins.; 75-ft. through plate girder, cost with floor erected complete, \$5,750. Base of rail on table to top of center pier, 3 ft. 11 ins.; base of rail to top of circular rail, 3 ft. 9 ins. The foundation, circular wall and center pier are constructed of concrete; the pit is usually paved with granolithic pavement. The cost varies in accordance with local conditions, ranging from \$2,500 to \$4,000.

For power we use: (a) air supplied by the engine being turned; (b) air supplied from compressors in adjacent shops; (c) gasoline engines; (d) electric motors. Electric motors preferred where current is available; air motors, supplied by compressors, second, and gasoline motors third choice. The cost of power installation varies from \$900 to \$1,200.

N. F. Helmers, Northern Pacific Ry.—The Northern Pacific Ry. are installing 80 and 85-ft. tables. I do not anticipate any power

in the future which will call for the use of a larger table. An 80-ft. through table, without the circle rail, and weighing 114,855 lbs., cost in place \$4,600. Such a table was installed at Staples, Minn., with concrete circle wall and center foundation. The masonry was done by contract, and the installation of the table by the company at an expense of \$3.92 per ton. The framing of ties and other timber cost \$4.05 per thousand feet. The cost was as follows:

	Labor.	Material.
Turntable	\$211.44	\$4,198.52
False work		12.93
Timber, ties, planking, etc.....	\$5.23	77.49
Painting	27.49	44.78
	<u>\$274.16</u>	<u>\$4,333.72</u>
Total cost (not including masonry)....		\$4,607.88

In 1908 an 80-ft. table of the same type was installed at Minneapolis replacing one 64 ft. in length. The foundation work was done under traffic, and the change of tables was done with a total interruption of 15 hrs.; itemized statement follows:

	Labor.	Material.
Excavation	\$ 463.94
Gravel	92.14
Concrete work	408.28	\$ 651.53
Forms	21.76	134.19
Circle rail	38.74
Table proper	361.86	4,040.95
False work for curbing.....	56.36
Removal of old brick curbing..	104.43
Cleaning girders	37.98
Painting	23.76	21.04
Ties and coping.....	79.71	188.89
Engineering	14.66
	<u>\$1,632.09</u>	<u>\$5,117.61</u>

The total cost was \$6,749.70.

I consider that ordinary conditions do not require the necessity of paving for the pit, but good drainage is essential in most cases.

For power we are using electricity and compressed air, while some of the 80 and 85-ft. tables are being turned by hand. Air motor in use at Jamestown, N. D., cost at St. Paul, \$450; installation, \$19.81; total, \$469.81. Electric tractor furnished by Nichols & Bro., cost \$1,104.37; installation, \$115.86; total, \$1,220.23.

W. T. Powell, Colorado & Southern Ry.—The up-to-date table should be 80 ft. long, with a capacity for turning 200-ton engines. We installed recently an 86-ft., 200-ton, through-plate girder table which cost as follows:

Table f. o. b. Denver, including circle rails.....	\$3,700.00
Material for concrete foundations and walls.....	1,090.00
Labor	1,600.00
Total cost	<u>\$6,390.00</u>

This table replaced a 66-ft. table and we were compelled to excavate and put in the curbing under 42 tracks and keep them safe

while in use. We drove 24 piles for center foundation and capped it with a block of concrete 12 ft. square and 4 ft. thick; a deck table of this length and capacity would cost about \$600 less. We use concrete entirely for masonry; rails are fastened with bolts and cast clips, the bolts being set in the concrete; no paving; drained when necessary. We use air power with a two-cylinder motor.

J. S. Browne, New York, New Haven & Hartford R. R.—We have recently installed an 80-ft. table at Providence. The center pier is of concrete, reinforced with steel rails, on account of the irregularity of the supporting material, as it was feared that the concrete might be fractured by the load if laid without reinforcement. The outer wall of the pit and the paving are also of concrete.

While an accurate record was not kept of the cost it was approximately as follows:

80-ft. steel table delivered at Providence.....	\$2,400.00
Placing coping and circular rail and moving table into pit	800.00
Concrete in outer wall and center, including forms.....	2,800.00
Excavation, including disposal of material.....	1,500.00
Paving	300.00
Drain pipe to connect with sewer.....	200.00
Total	\$9,000.00

The work was done by the company's force, and the high cost of excavation was due to the fact that a portion of the work was done in freezing weather, and it was necessary to handle the material more than once before its final disposal by work trains.

The company's standard main line turntable is 75 ft. long, but 80 ft. is considered better at points where the largest type engines are turned, to permit of properly balancing them. Deck plate girder tables are used where sufficient depth is available without excessive cost, but where this is not feasible, half through plate girder tables are used. The superstructure of deck tables is about 30% cheaper than that of half through tables, but this saving is balanced by the greater cost of the pit, so that under ordinary conditions the total cost of these two types is about equal. Gasoline motors are generally used for power, although electric motors may be used to considerable extent in the future.

J. N. Penwell, Lake Erie & Western R. R.—On our main line, we are taking out 62-ft. tables and replacing with 80-ft. tables, using the old ones on the branch lines. We have two of the old cast-iron tables, 50 ft. in length, which have been in use 20 yrs., one of which is in perfect condition and the other about worn out. We have only one of the old style gallows frame tables, but it is out of date and will be replaced with a more modern structure within two years. For the foundation and circle walls we are using concrete. If foundation is not absolutely reliable, we drive piles. Drainage is important and the very best should be provided. Our tables are all operated by hand, except one which we are now operating with air. Would recommend electricity wherever it can be had. In erecting new tables we make provision for air pipes in the foundation, so that we can use air in the future if we desire.

Cost of Turntables.—The following was the estimated cost of turntables for the N. Y. Central Ry., in 1902:

Size of Turntable.	70 ft.	75 ft.	80 ft.	85 ft.
Turntable delivered, f. o. b.	\$1,965	\$2,400	\$2,600	\$2,800
Labor erecting	385	430	480	500
Pit	3,600	3,800	4,000	4,200
Mortar for turning.....	900	900	900	900
Total	\$6,860	\$7,630	\$7,960	\$8,400

Cost of Ash Pit.—On the Northern Pacific a standard ash pit with brick side walls and concrete bottom was built at a cost of about \$9 per lin. ft. in 1890. The width between the side walls is 4 ft., and the clear depth of the walls is $2\frac{1}{2}$ ft. below top of rail. The brick side walls are 17 ins. thick. The sides of the pit are protected by cast-iron plates, $\frac{1}{2}$ in. thick, 18 ins. wide, and 3 ft. 4 ins. long. The bottom of the pit is paved with hard brick set on edge and bedded on 8 ins. of concrete. This concrete foundation extends under the side walls where it is thickened to 12 ins. for a width of 2 ft.

On the N. Y. Central in 1902, the following was the cost of different types of ash pits:

Elevated ash pit, \$13 per lin. ft., plus \$39 for the two ends.

Semi-depressed pits on the main line, \$20 per lin. ft.

Ditto, for minor pits, \$15 per lin. ft.

Cost of Snow Sheds.—On the Northern Pacific R. R. (in 1890) the standard snow shed on level ground consisted of timber bents (8 x 10-in.), 6 to 10 ft. apart, to which were fastened horizontal studding (4 x 10-in.), and to the studding was spiked 2-in. upright siding. The roof was double-pitched, with rafters 4 x 10-in., and sheathed with 2-in. plank. For wet snow, the bents were spaced 6 ft. apart, requiring 304 ft. B. M. and 13.3 lbs. of iron per lin. ft. of snow shed. At \$30 per M., and 5 cts. per lb., the cost was not quite \$10 per lin. ft. of shed.

The standard snow shed in through cuts (single track) has bents 6 ft. apart, and it requires 484 ft. B. M. and 14 lbs. of iron per lin. ft., the cost being \$15 per lin. ft.

A standard side-hill snow shed, with a flat roof, with bents 6 ft. apart, contains 684 ft. B. M. and 10 lbs. of iron per lin. ft., costing \$20 per lin. ft.

None of the foregoing have any cribwork, being entirely sawed timber. Nor is any extra excavation involved in their construction. These sheds are not designed to resist snow slides or avalanches.

In Trans. Am. Soc. C. E., Vol. 29, 1888, Mr. Thomas C. Keefer has described and illustrated the types of snow sheds built (1887) in the Selkirk Mts., on the Canadian Pacific Ry. Fifty-three sheds total 7 miles long, were built.

The typical "avalanche shed" has a log, rock-filled crib, forming a retaining wall back of which is an earth fill. This forms the uphill side of the shed. The roof and downhill side are of sawed timber. The cost ranged from \$40 to \$70 per lin. ft. of "avalanche shed."

Where cribwork was not needed, "gallery sheds" were built at a cost of \$15 to \$40 per lin. ft.

Cost of Snow Fences.—The standard portable snow fence of Chicago, Milwaukee & St. Paul has the following bill of material for a panel 16 ft. long:

Legs, 2 pieces 2 x 6-in. x 14-ft., No. 1 Common.

Boards, 11 pieces 1 x 6-in. x 16-ft., No. 2 Fencing.

3 carriage bolts, $\frac{1}{2}$ x 5 ins.

3 No. 10 — 0.1 lb.

66 wire nails, 8d. = 0.5 lb.

60 wire nails, 10d. = 0.7 lb.

When stakes are used to hold the legs down, use 6 stakes cut from 2 x 4-in. x 2-ft. No. 1 common ripped diagonally, and fastened to the legs with a total of 12 wire nails (20d.).

When ground is frozen, use drift bolts instead of stakes, using 6 drift bolts ($\frac{1}{2}$ x 15-in.) and 12 wire staples (3-in.).

This fence contains 130 ft. B. M. per panel 16 ft. long, and weighs 327 lbs. when made of green lumber. In 1899, the cost was \$1.60 per panel, f. o. b. cars, complete with stakes and spikes.

On another Northwestern railway, the cost per 16-ft. panel was:

124 ft. B. M., at \$16, incl. nails.....	\$1.89
Labor	0.11
Total	\$2.00

On another road the cost per 16-ft. panel was:

152 ft. B. M., at \$17.....	\$2.58
Nails	0.10
Bolts	0.05
Labor	0.25
Total	\$3.08

On the C. & N. W. Ry. a stationary snow fence is largely used. Cedar posts, 12 ft. long, are set 4 ft. in the ground and 8 ft. apart. The boards are 1 x 10-in., spaced 2 ins. apart, leaving an open space of 12 ins. next to the ground. The cost of this fence per 16-ft. panel was as follows, in 1900:

86 ft. B. M. boards, at \$14.50.....	\$1.29
2 cedar posts, at 30 cts.....	0.60
1 $\frac{1}{4}$ lbs. 10d. nails, at \$2.40.....	0.04
Labor	0.60
Total	\$2.63

For costs of right of way fences see the index under Fences.

Cost of Mail Cranes.—On the St. Louis & Southwestern Ry., in 1902, the standard mail crane cost:

Crane and materials	\$12.00
Labor	6.85
Total	\$18.85

This was a wooden mail crane. A common cost of wooden mail cranes is \$12 to \$15, erected in place. Iron mail cranes cost about \$25 in place.

Cost of Interlocking Signal Plant and of Operation.—Mr. J. A. Peabody estimates that the average interlocking plant will have a life of 20 yrs., but, to be on the conservative side, assumes 15 yrs. He estimates such a plant will cost \$8,000, including cross-over, 4 derails, 4 high signals and 8 dwarfs.

To operate and maintain this plant would cost:

	Per year.
Interest, 4% of \$8,000.....	\$ 320
Depreciation, 7%	560
Maintenance, 10.5%	840
Operation	1,440
Total	\$2,800

He estimates that where there are 17 trains stopped daily, at a cost of 45 cts. per stoppage, the yearly cost is \$2,500 for stopping trains. Any greater number of trains would justify an interlocking plant merely to save the expense of stopping trains.

See *Engineering-Contracting*, February, 1906, p. 49, for Mr. Peabody's complete discussion.

Definition of "Mile of Railway."—In discussing railway costs per "mile," there is great danger of confusion, for there are three kinds of "miles of railway": (1) The mile of roadbed, equivalent to the mile of right of way; (2) the mile trackway, including all 1st, 2d, 3d and 4th tracks upon which trains travel regularly between stations; and (3) the mile of track, including all tracks of every nature, main, branch, side tracks, yard tracks, etc. Due to the different meanings assigned to the "mile of railway," I have abandoned the use of that term, and for this book I have adopted the three terms above used: (1) Roadbed, (2) trackway, and (3) track.

The Interstate Commerce Commission uses the word "line" when referring to "roadbed."

Many engineers use the word "line" when referring to "roadbed."

The term "main line" is also ambiguous, as many people use it to include "branch" lines.

The word "branch" has no definite meaning, as a rule, and refers merely to lines having a light traffic, and generally to lines that branch from the main line and do not carry "through traffic."

"Spurs" is another ambiguous term. A short branch line, especially one that serves only one class of traffic, is commonly called a spur.

Logging "spurs" are often merely temporary lines, too long to be called "sidings," and yet not of a character worthy of being designated as branch lines.

"Sidings" are short lengths of track at stations, where trains pass, and where cars await loading and unloading; also short tracks

serving factories, mills, etc. Sidings merge into "yard tracks" at large stations.

Average Cost of Railways in America.—Many generalizations founded on meager data have been made as to the probable average cost of American railways. The Interstate Commerce Commission receives annual reports from all railways, and those reports give the "cost of road." The last report of the Commission, for the year 1906, gives the following as the total of all roads, taken from the general balance sheets of American railways:

Cost of road.....	\$11,588,922,421
Cost of equipment.....	881,365,517

Neither of these figures means what it seems to mean. The following was the total mileage:

Single track (=roadbed).....	222,340
1st, 2d, 3d and 4th track (=trackway).....	242,822
All tracks, including sidings, etc.....	217,083

According to this, the "cost of road" would be \$50,200 per mile of roadbed, and cost of equipment would be \$3,740 per mile of roadbed. The first is too high and the second is too low. The "cost of road" is, in large part, the price paid for it by its present owners; and, as nearly all American roads have changed hands at least once, it is evident that this price is more nearly a function of value based on net earnings than it is a function of actual cost of construction.

The "cost of equipment" is far below the actual cost of new equipment, since most roads report the depreciated or second-hand cost of equipment. Indeed, it seems that some roads report merely a nominal cost of equipment to escape taxation.

The capital stock and funded debt (=bonds) reported for 1906 was as follows:

Funded debt	\$ 8,068,004,746
Capital stock	6,929,670,224
Total	\$14,997,674,970

From this it follows that the following stock and bonds were outstanding per mile of roadbed:

Funded debt	\$26,200
Capital stock	21,200
Total	\$47,500

Since nearly all American railways have been built with money secured by the sale of bonds, it is evident that the average American railway (including equipment) has cost at least \$26,200 per mile of roadbed. The capital stock largely represents the capitalized value of the net earnings, although in some instances it represents money actually expended in construction and equipment.

Of the \$76,458,000 spent in building and equipping the 1,645 miles of the Northern Pacific Railway in Washington, \$8,848,000 was ex-

pended for improvements (exclusive of equipment) since the original construction. If this is typical of average expenditures for railway improvements throughout America, it would be necessary to add about 10% to the \$36,300 above given, which would make the average cost of construction and equipment about \$40,000 per mile. It has been the common practice to make most improvements out of earnings, without issuing bonds; hence it is reasonably certain that American railways have actually cost at least \$40,000 per mile of roadbed for construction, land and equipment. Nor do I believe that this cost has been much exceeded. On the other hand, the cost of reproducing the same roads to-day would probably exceed this sum, and might exceed it very much, the reason being that land values have appreciated so greatly since the roads were built. This is well brought out elsewhere in this book where the original costs and costs of reproduction of Washington railways are given.

Cost of Railway Lines.—In *Engineering Magazine*, December, 1895, Mr. J. F. Wallace gives the following estimates of the average cost per mile of single track roadbed in the United States:

Class of Railway.	A.	B.	C.
Right of way.....	\$ 1,000	\$ 1,500	\$ 2,000
Proportionate expense of terminals...	500	1,500	5,000
Bridges and culverts.....	1,500	2,500	4,000
Grading	3,000	6,000	12,000
Track laid	6,000	6,500	7,000
Ballast (rock)	2,500	3,000
Fencing	300	400	400
Telegraph	200	250	250
Stations and water supply.....	500	800	1,200
Engineering	400	500	700
General and legal expenses.....	300	400	600
Equipment, cars and locomotives.....	1,500	2,500	4,000
Total	\$15,100	\$35,350	\$40,150

Class "A" is a branch line, 2 passenger and 4 daily freight trains.

Class "B" is a secondary line, connecting small cities.

Class "C" is a trunk line, 30-lb. rails.

It will be noted that the item of "Engineering" is considerably below what it actually cost the various railways in the state of Washington. See pages 1303, 1306 and following.

In fact, Mr. Wallace is low, in my judgment, on nearly every item enumerated, excepting, perhaps, general and legal expense.

Cost of a Mining Railway.—Mr. John H. Pearson gives the following cost of The Winchester & Beattyville R. R., built in 1893. The road is 8 miles long, and has 9 miles of track including sidings. It was built to open up a mining district, and it runs through rugged country. No grades exceed 1%, and the maximum curve was 6°, except two 12° curves. The cost per mile of roadway (8 miles) was as follows:

	Per mile of roadbed
1. Preliminary surveys	\$ 19
2. Locating surveys	111
3. Engineering during construction	375
4. Stationery	28
5. Office furniture	6
6. Tools	83
7. Grading roadbed	2,233
8. Trestles (at \$23 per M in place and iron at 5 cts. per lb.)	1,332
9. Culverts	159
10. Legal expenses	10
11. Right of way	428
12. Cross ties (31 cts. each) and handling	696
13. Rails (56-lb. relayers, at \$25 per ton)	2,370
14. Track fastenings	506
15. Switches	140
16. Ballast (1,000 cu. yds.)	330
17. Fences and cattle guards	41
18. General expenses	220
19. Tracklaying and surfacing and repairs	938
20. Water station (\$1,380)	172
21. Depot and other buildings (\$1,320)	165
22. Engines, cars and repairs (\$6,013)	752
23. Fuel, oil and waste	83
24. Conducting transportation	321
25. Telegraph line
26. Three coal and lumber switches	2,021
Total	\$13,850
Net revenue from operation (\$6,000)	750
Balance	\$12,900
Deduct equipment	714
Total cost of construction	\$12,186

Since there was 1 mile of side track to 8 miles of roadway, the above costs should be divided by 1.125 to arrive at the cost per mile of track. Multiplying by 0.9 will give almost the same result.

Wages were low at that time, common laborers receiving \$1.25 a day; teams, \$3.50; single mule and driver, \$1.75; foremen, \$2.00.

Cost of a Logging Railway, Pennsylvania.—Mr. William Barclay Parsons, in *Trans. Am. Soc. C. E.*, Vol. 25, p. 119, briefly describes the location and construction of 7 miles of standard gage logging railroad built in Northwestern Pennsylvania in 1890. The maximum curve was 18°, and the ruling grade, 3.2%. The country was heavily wooded with hemlock and very rough; clearing and grubbing costing \$50 to \$60 an acre for a right of way 50 ft. wide. Cuts were 16 ft. wide and fills 12 ft. Log culverts were used under banks 10 ft. or less in height. The excavation averaged nearly 11,000 cu. yds. per mile, of which 7.6% was rock, 11% loose rock, 25.2% tough clay (1 pick to 1 shovel), and 46.2% earth, most of which was heavy soil. The clearing and grubbing, log culverts and excavation when charged up to the excavation cost 46½ cts. per cu. yd., or about \$5,000 per mile. (The excavation alone probably cost about 40 cts. per cu. yd. The toughness of the earth and the presence of roots made the excavation expensive. Wages were prob-

ably \$1.25 per 10-hr. day.) The cost of one mile of finished road on the heaviest part of the line was as follows:

62.86 tons of 40-lb. rails, at \$33.00.....	\$2,074.38
352 joints complete, at \$0.55.....	193.60
6,200 lbs. spikes, at \$0.0225.....	139.50
3,000 cross ties, at \$0.15.....	450.00
Freight on materials.....	159.00
Tracklaying	400.00
Grading	5,026.89
Trestles (at \$17 per M in place).....	250.45
Surveys, inspection, etc.....	400.00
Total per mile.....	\$9,093.82

Cost of a Short Branch Line, Texas.—In 1903 a first-class branch line was built in Texas to give the St. Louis Southwestern an entrance into Dallas. The line is 12.13 miles single track and has 1.52 miles of sidings, total 13.65 miles of track. The line is almost entirely tangent, and follows a ridge.

	Total.
Engineering	\$ 6,323
Grading	48,924
Bridges, trestles and culverts.....	41,661
Ties	26,838
Rails (75-lb.)	37,607
Track fastenings	5,596
Frogs and switches.....	1,177
Ballast	30,526
Tracklaying and surfacing.....	9,511
Crossings, cattle guards and signs.....	1,929
Total	\$210,092

It will be noted that land and equipment are not included, nor interest during construction.

Engineering cost about 3%, and tracklaying and surfacing cost about \$700 per mile of track.

Cost of a Cheap Railway, Georgia.—Mr. A. Pew, in *Trans. Am. Soc. C. E.*, Vol. 23, in a paper entitled "The Cheapest Railway in the World," gives the following as the cost of a 19-mile railway in Georgia:

Cost per mile of road and track.....	\$3,440
Cost per mile for equipment.....	1,000

The roadbed was only 10 ft. wide in fills and 14 ft. in cuts, and the excavation averaged 4,000 cu. yds. per mile. The excavation cost only 9 cts. per cu. yd., wages of laborers being \$1 per 10-hr. day. The ties cost only 10 cts. each, and 45-lb. rails were used.

Report of H. P. Gillette to the Washington Railroad Commission on the Valuation of the Railways.*—Before explaining the methods pursued in making the appraisal, it is as well to record the fact that the state of Washington is the first state in the Union to complete the valuation of its railways for the express purpose of using these values as a basis for rate making. Only one other State

**Engineering-Contracting*, April 7, 1909.

Railway Commission takes priority over the Washington Railroad Commission in point of time of completing a valuation of the railways within the state, namely, the Texas Railway Commission; but it should be remembered that the object of the valuation of the railways of Texas was not for the purpose of rate making, but for the purpose of limiting the issues of stocks and bonds—that is, to prevent "stock watering"—which presents quite a different problem from that presented to the Washington Railroad Commission. Vastly greater interests are at stake than when railway values are to be used merely to limit the issue of stocks and bonds of railways chartered within the state. Hence, both the scope of my investigation of railway values, and the methods used were radically different and necessarily much more complex than prevailed in the Texas appraisal. For example, in the following out of the requirements of the Washington statute, you felt impelled to secure all the data enumerated by the Supreme Court of the United States in the celebrated Nebraska rate case known as the *Smythe v. Ames* case. The Supreme Court held in its decision of that case that a rate-making body must consider, among other things:

First. The original cost of the railway, plus improvements and betterments.

Second. Its cost of reproduction new.

Third. Its present value, ascertained by deducting its depreciation from its value new.

Prior to this Washington railway appraisal, no railway commission in America had ever attempted to comply with the decision of the Supreme Court in the Nebraska case, and I believe that all the failures on the part of other railway commissions in their rate-making efforts may be traced directly to their fundamental failure to follow the Nebraska rate case decision. Flat rate making has proven abortive, because of attempts to make rates without full knowledge of all the factors which the Supreme Court has held to be necessary in forming an intelligent judgment; and prominent among these factors are the original cost, the cost of reproduction, and the present value.

Two other states besides Texas have made railway appraisals, namely Michigan and Wisconsin; but in neither of these instances was the appraisal made by a railroad commission. Both the Michigan and Wisconsin appraisals were made for the purposes of taxation, and were not governed by the Nebraska rate case decision.

The state of Washington is the first state to secure the *original* cost of the railways within its boundaries and is, therefore, the first state to investigate the accounting records of the railways with the object of ascertaining the actual original cost and the cost of improvements and betterments.

I mention this fact not merely for the purpose of putting on record the priority which the Washington Railroad Commission can justly claim in following the law as laid down by the Supreme Court, but for the purpose of making clear the magnitude of the task confronting the commission and its engineers and experts.

Speaking for myself, I found the precedents established by Texas, Michigan and Wisconsin of little value, either in deciding the methods to be pursued in making the appraisals or in estimating the probable cost of the appraisal. I ascertained that the state of Wisconsin had spent about \$11 per mile of railway for making the appraisal and the railways themselves had spent an equal sum, making a total of about \$22 per mile for the joint work done by the state and by the railways, for they both worked together in making the appraisals. When I started the appraisal of the railways of Washington I believed that the appraisal would cost far less than \$11 per mile, and I am glad to say that the cost has actually been not more than \$12 a mile, although I regret that it was even as much as that. I had no precedent to guide me in estimating the cost of going through the accounting records of the railways, and I underestimated the time and labor involved in that undertaking. Railway accounting records nearly 40 years old had to be discovered and analyzed. I say "discovered," for the railways themselves did not know the nature of these early records, even if they knew of their very existence, which in many cases they did not.

At this point it may be well to explain that these early records are far from being worthless, as many persons have assumed, for the subsequent improvements and betterments can be added to these original costs, and thus bring the total cash expenditures down to date. This total cash expenditure is a wonderful aid to the engineer in estimating the cost of reproduction. To illustrate by an example, take the actual cost of the item of "Engineering" on the Northern Pacific Railway. Up to June 30, 1906, it has amounted to \$2,800,000 for the state of Washington, or about 6% of the total actual cost of construction and betterments. An investigation of this seemingly high percentage disclosed two big items, one being about \$200,000 for the exploration surveys in the Cascade Mountains. At the time these surveys were made, no maps were in existence, and the railway engineers were compelled to explore the entire Cascade Range from the Canadian boundary south to the Columbia River. To-day, in reproducing the Northern Pacific Railway, no such elaborate exploration is necessary, and, if it were eliminated, the cost of engineering would be reduced to \$1,600,000. In like manner certain other items of engineering would be reduced, so that the total cost of engineering should not exceed \$2,500,000, which is the sum that I used in estimating the item of engineering when making my estimate of the cost of reproduction. It would take several hundred pages to explain my analysis of the original costs, and my use of the data thus obtained in guiding my judgment as to a proper allowance for the cost of reproduction of each item. I wish, however, to say had I not secured the original costs I am positive that my costs of reproduction would be nothing better than engineering guesses in so far as certain items are concerned. For example, the cost of grading, especially through rough and mountainous country cannot be accurately ascertained to-day by

any engineer not possessed of the original records showing the quantities, and classification of excavation, or of the actual costs of doing the grading work. It is true that in the entire absence of original records of any sort, an engineer can go into the field, and cross-section the existing "cuts" and "fills," and make an estimate of yardage of the different classes of excavation, but I should never do this except as the very last resort, and then with the determination of adding a very large percentage for contingencies.

I may state at this point that one of the most potent reasons for securing the original quantities and original costs is to eliminate the item of "contingencies" entirely. It sounds little enough to speak of 10% added for "contingencies," but it would have meant adding just \$5,000,000 to my estimate of the Northern Pacific Railway alone.

Reverting briefly to the cost of appraising the railways of Washington, attention should be called to the lack of logic in estimating the cost of such appraisals in terms of the mile as the unit. The Wisconsin appraisals cost \$22 a mile, but the Wisconsin railways have an appraised value of only \$20,000 a mile; hence the Wisconsin appraisal cost 70 cts. per \$1,000 appraised. The Washington appraisal cost \$12 a mile, but the Washington railways have an appraised value of \$60,000 per mile; hence the Washington appraisal cost 20 cts. per \$1,000 appraised, as against 70 cts. in Wisconsin. There is not the slightest doubt that it costs more per mile to appraise a line worth \$60,000 a mile than to appraise one costing \$20,000 a mile, if the same methods of appraisal are used; for the \$60,000 line contains many more structures and details per mile, and higher land values, involving more labor on the part of both accountants, engineers and right-of-way appraisers. If this is so, it will be asked why the Washington appraisal cost less per mile than the Wisconsin appraisal. An answer leads me into the subject of the methods used in making the Washington appraisal, for upon those methods depends the relative economy.

Methods of Appraisal.—Before entering upon the task of appraising the Washington railways I had secured all desired information as to the appraisals of the railways in Texas, Michigan and Wisconsin. I also saw the engineer of the Minnesota Railway and Warehouse Commission, who had been engaged for six months on the appraisal of the Minnesota railways. I found that the Wisconsin and Minnesota methods of appraisal were practically identical. Both states furnished printed blanks to the railways, and required the railways to make a detailed estimate of the cost of their own property. Upon securing such estimates, the states' engineers checked up the appraisal. This method is advocated largely on the ground that it avoids duplicating the expense of an appraisal, the assumption being that each railway itself will make its own appraisal in any event, whether asked to or not. Therefore, if the railway is required to make its own appraisal first, the state's engineer need not go through all the details, but can accept most of the matter after a more or less cursory inspection.

I was wholly dissatisfied with this method, for I felt that it would make it almost imperative for me to accept the appraisals made by the railways, practically at their own figures, or to undertake in the end what I could just as well undertake in the beginning, namely an independent investigation of my own. I need scarcely say that the results of the investigation have served to confirm my position on this point.

Neither the state of Minnesota nor Wisconsin had gone into the matter of the actual cost of the original railway property. This seemed to me a serious omission, not merely because of the Nebraska rate case decision, but because of the invaluable data that an investigation into actual costs would disclose.

In estimating the present or depreciated value of structures, rolling stock, etc., both Michigan and Wisconsin had sent experts into the field to estimate the percentage of present value of each unit. In this manner 40,000 freight cars were inspected in Michigan, and their "present value" estimated. To me this seemed to be not only a useless procedure, but very erroneous. Aside from the great expense of thus inspecting each car and structure, I was influenced by a belief in the far greater accuracy of applying what might be termed "mortality tables of structures." If the age of a man is known, his expectation of life can be estimated from mortality tables. Insurance companies do not have their doctors guess at the man's probable life. The doctor merely reports the man as not suffering from disease, and the insurance company having the man's age, applies its mortality tables. In like manner, it seemed to me, the "present value" of a car or locomotive could be accurately estimated if its present age were known. It is a well-established fact that a freight car has a useful life exceeding 20 or 25 yrs. If the average car has a life of 25 yrs., it loses 4% of its life every year. Hence, by multiplying its age in years by 4%, its lost life or depreciation is accurately ascertained; and by subtracting this depreciation from 100 the remainder will give its "present value," expressed as a percentage of its value new.

I believed that it would be far less expensive to ascertain the age of each car and each structure from the records of the companies, and to estimate the present value by the method just explained, than to inspect each structure in the field. This proved to be the case, and it effected a very substantial saving in the cost of appraisal, while, at the same time, it yielded more reliable results.

In some cases the records in the engineering offices of the railways did not show the ages of existing structures, but in such cases their accounting records showed the dates when structures were built, or when cars were purchased.

If practically all the structures shown in the accounting records are still in existence, and the money expended each year for each class of structure is known, it is a very simple matter to figure the average age of the money invested in such structures, which, after all, is what is needed in estimating present value. To illustrate.

suppose there are a number of station buildings in existence, whose age is not known. Suppose, however, that \$10,500 was spent for such buildings in 1896, \$20,000 in 1900, and \$5,000 in 1902. Then, in 1906, the average age of the money invested in these buildings is ascertained thus:

$$\begin{array}{rcl}
 \$10,500 \times 10 \text{ yrs. equals } \$105,000 \text{ one year} \\
 \$20,000 \times 6 \text{ yrs. equals } \$120,000 \text{ one year} \\
 \$5,000 \times 4 \text{ yrs. equals } \$20,000 \text{ one year} \\
 \hline
 \$35,500 \times 7 \text{ yrs. equals } \$248,500 \text{ one year}
 \end{array}$$

This gives a total of \$35,500 invested 7 yrs.; for $\$35,500 \times 7$ yrs. equals \$248,500 one year.

The rule to be followed in all such cases is to multiply the money expended each year for structures of a given class by the age in years, add all these products together, and divide by the total cost of all the structures under consideration. The quotient is the average age of all the structures, or, more strictly speaking, the average age of the money invested in the structures. If some of the structures are no longer in existence, this method can still be applied. Take railway cross-ties, for example. Ascertain the total value of cross-ties in the track, then go back through the records of cost and tie renewals, by years, until the total cost of the renewals adds up to the total value of ties now in the track. Then compute the average age as above shown. If the price of ties has fluctuated, ascertain the actual price paid, and reduce all yearly expenditures of renewals to the present price.

It will be impossible, as well as undesirable, in a report of this character, for me to indicate all the methods pursued in the appraisal of railways, but some of the radical departures from precedent should be outlined, particularly where a result is secured in more thorough or in a more economic manner. Moreover, any chief engineer who may be in your employ in the future will be greatly handicapped without an outline of the methods pursued in this original appraisal.

In searching the records of the railways, I did not confine myself merely to their engineering and their accounting books, but often found missing links of information in the most incongruous places. The Oregon Railroad & Navigation Company, for example, had practically none of its "construction ledgers," and at first we despaired of being able to piece together a complete itemized summary of original cost. Finally we found an old tissue copy book, Book No. 51, at the Ash St. Dock in Portland, containing copies of the auditor's distribution sheets, showing costs of engineering, grading, etc., etc.

For several months our work was considerably retarded, not only by the reluctance of several of the railway companies to assist us in finding their records, but by the incompleteness of the records when found. Little by little, however, we were able to fill in the gaps, until there remained not 10% of the original unascertained.

For the guidance of any engineers whom you may employ in the future, I give a list of the most important records to be looked for in making an appraisal of this character.

1. Annual reports to stockholders.
2. Annual reports to Interstate Commerce Commission.
3. Annual report of chief engineers and superintendents to the president of the road.
4. Reports of minor officials.
5. Progress profiles.
6. Cross-section and quantity books.
7. Final estimates on contract work.
8. Tissue copy books of final estimates.
9. Rail and ballast charts.
10. Bridge books (engineering department).
11. Building books.
12. Work orders.
13. A. F. E.'s (authorization for expenditure).
14. Accounting records (a) Construction Ledgers, (b) General Ledgers and their accompanying journals, (c) Vouchers, Registers, (d) Vouchers, (e) Auditor's Distribution Sheets, and the like.
15. Equipment Registers.
16. Distribution Book, or Disbursement Accounts Books, containing directions for accountants to follow.
17. Confidential Reports.

In my judgment the first step to be taken in appraising a railway is to ascertain its physical and financial history. For this purpose the annual reports to stockholders are an invaluable source of information. By a perusal of these reports an historical map or chart can be prepared showing the limits of each "construction division" or branch of the railway, and the dates of beginning and completing the construction work on it. The present "operating divisions" often have the same names as certain "construction divisions" of the road, but wholly different limits. Hence the necessity of an historical map in order to avoid confusion in interpreting the accounting records of the road.

Having prepared a map, and a brief history of the road, the next step should be an investigation of the accounting department records. The tendency of a civil engineer is to go to the engineering records first, but this is a mistake, for the accounting records are usually kept in a much better shape, and contain fewer gaps. From the construction ledgers, an itemized account of the original cost of each construction division is secured, and having been secured, the next step is to check it by the records of the engineering department, where quantity books and tissue copy books of final estimates paid to contractors, and the like, are usually to be found. Frequently, however, it happens that a line has been purchased, and that only the engineering records were transferred at the time of the purchase. In which event it may be impossible to secure the

accounting records, except by going to the original owners of the property.

Having gone rapidly through all the accounting and engineering records to ascertain what gaps, if any, exist as to original construction data, the next step is to put engineers into the field to supply the missing links by actual inspection, measurement, etc. An attempt to estimate by field survey should be the last resort, not only on account of the greater cost of field work, but because of its greater inaccuracy, and finally—but not to be ignored—because, in case of a legal dispute as to the estimated cost, field surveys, and estimates made by different engineers are likely to differ widely. There is always so much that cannot be seen, like the foundation of bridges, the percentage of loose rocks in embankments, etc., that a field survey should be used only as a last resort. And, in our appraisal of the Washington railways, field surveys were made only for a very small percentage of the total mileage.

A field inspection of every mile of track should be made, preferably by an engineer riding on a handcar. This engineer should be provided with complete, up-to-date profiles, and small scale plans of the road, showing all structures and their dimensions, etc. I made the mistake of accepting the existing profiles and plans for use by the field inspectors. These records were so often incorrect, through not having been kept up to date, as to cause much unnecessary work subsequently in checking. Haste in sending out field inspectors is a mistake, as field inspection of this sort is the most inexpensive item of an appraisal, and can be quickly done even with a comparatively small force. One man on foot will inventory about 12 miles of ordinary track each day, or twice that amount on a handcar. Field inspection, therefore, should not be begun until corrected, up-to-date profiles and maps have been prepared, and until the investigation of the engineering records has been carried far enough to disclose the particular structures upon which the office records are incomplete. By doing this, the field inspection resolves itself into a checking off of structures with an occasional pause to measure some structure on which the office records are defective.

The appraisals heretofore made in other states have been based almost entirely upon field surveys and inspection, no attempt having been made to secure the necessary data from the engineering and accounting records of the railways. Why? The answer is found in the purpose of the appraisal. As previously stated, the purpose of the appraisals in Texas, Michigan and Wisconsin was not the same purpose as in Washington. Where the purpose is taxation, a railway naturally seeks a low valuation for its property, hence it prefers to refuse access to its own records, believing—and believing rightly—that what cannot be seen with the eyes will not be likely to appear in the appraisal. An appraisal by field examination wholly is very apt to be below the true value of the property, hence the acceptability of such an appraisal by the railways where taxation is the purpose of the appraisal.

Several of the principal railway system in Washington at first resisted our efforts to secure the records in their offices, and stated that the records were so incomplete as to be valueless. In some instances I have no doubt that this was an honest opinion. I am inclined to believe, however, that their motive in resisting an examination of the records was, in some cases at least, to secure an appraisal which could be fought in the courts, and probably upset by documentary evidence to prove its unreliability in parts, if not in its entirety. Therefore, I hold to the belief that an investigation of both the accounting and engineering records of the railways would have been the best policy, even had it cost many times what it did cost. And, to show my reason for this belief, I will cite just one example. In testifying before your honorable body, Mr. Hogeland, chief engineer of the Great Northern Railway, has estimated the cost of earth excavation to be made up of three different items, as follows:

	Per cu. yd.
Average contract price up to 1,000 ft. haul.....	\$0 236
Average overhaul	0 036
Transportation of men's tools, supplies.....	0 045
Total	\$0.310

Had we not secured the actual records in the Great Northern offices, it might have been a difficult matter to convince the court that the last two items of the above estimate are ridiculously high. Having the records, it will not be so difficult. For example, the actual cost of the item of "average overhaul" was just one-seventh of Mr. Hogeland's estimate, or one-half cent per cubic yard, as shown in my statement of the actual cost of construction of the Great Northern Railway in the state of Washington. The item of transportation of men was similarly overestimated.

I will not enter into such details further, but, in justice to myself and you, I feel it my duty to explain *why a departure from precedent in railway appraisal was the best policy*. Such an illustration as the above will serve better than many generalities to show the character of the reasons for our exhaustive investigations into the original cost of the railways of this state. Were you, as a court, or were any other court, confronted by the conflicting testimony of expert engineers, it would be difficult to arrive at a just opinion as to proper quantities and prices, unless the actual data were available to guide you. The data are available and are now in your possession.

I have not touched upon the very important matter of the appraisal of the rolling stock, or equipment, further than to say that I did not make a field inspection of it. The office records were so complete that such an inspection was superfluous, and for the reason above given. In order to apportion to the state of Washington its share of the cost of the rolling stock, it was necessary to

appraise the entire equipment of every railway system entering the state. This, in itself, is no slight task. Several states should share the cost of appraising the equipment of the railways, so that the whole cost would not fall on one state, as in this instance.

If Washington, Idaho, Montana, the Dakotas and Minnesota could have acted in concert, the cost of railway appraisal would have been very much less, not only because of the distribution of the cost of appraising the equipment, but because of the facility with which an entire railway system can be appraised once an engineer becomes familiar with the accounting and engineering records of that railway system. For this reason, as well as for others, the railroad commissioners of certain groups of states should strive to act together.

The appraisal of right-of-way lands and station grounds, as far as present value goes, was delegated principally to three right-of-way experts, men who had been buying lands for railway purposes in Washington and were familiar with prices. Your honorable body adopted a method of arriving at land values which was entirely novel, and, to my mind, a vast improvement over any other method hitherto used in other states. The method consists in calling in real estate men in all the large cities, and securing testimony from those men as to land values. Your honorable body, sitting as a court, hears the testimony not only of the regularly employed right-of-way experts, but of expert real estate witnesses, which those right-of-way experts have consulted, and other real estate experts which the railways may bring in. Hitherto the practice has been to examine all real estate transfers within a certain distance of the railway property, and for a period of years prior to the appraisal, and to base the appraisal upon these transfers. Since property for railway purposes usually costs more than for other purposes, it is necessary to multiply the value ascertained from transfers of adjacent property by some factor, this factor being ascertained from expert testimony or otherwise. Unfortunately the records of the real estate transfers are not the best evidence of the value of the property transferred. Indeed the records are often made so as to conceal the real value of the property. For this reason alone the method devised by your honorable body is much to be preferred. Moreover, it is a less expensive method of appraising lands.

As to my methods of appraisal I need say little more. My testimony before your honorable body is complete on those matters, but, being of great length, I have thought it wise to summarize certain features in this report, giving also a few suggestions, which may assist any engineer who may be in the employ of the Washington Railroad Commission in future.

It is needless to tell you, but for the sake of public record I desire to say that on all the smaller railways in Washington I was given most courteous treatment, and had ready access to all records. On the three large systems, namely the Great Northern, the

Northern Pacific, and the Oregon Railway & Navigation Company, I met with much resistance at first, and lost several months of time in consequence. Denial as to the existence of certain important records was repeatedly made—records that I subsequently found. Possibly these denials were made in good faith, but, since free access to all records was not given me by the Great Northern and the Northern Pacific for a long time, and then only after I pieced together enough information to prove the existence of the desired records, my work was greatly retarded. I think that these railways came ultimately to see that it was an error not to put all records at my disposal, and all I regret is that they were not prompt in reaching that conclusion. I regret it not only because of the increased cost of the appraisal, but because I had business duties in New York that made my return imperative at as early a date as possible.

In conclusion I wish to express my hearty appreciation of the loyalty and zeal with which my assistants worked. Those in the most important positions worked not only by day but by night. I know of no one who seemed swayed by the fear of "working himself out of a job." My two principal assistants, Mr. Francis W. Collins and Mr. H. L. Gray, deserve special recognition in this report, for upon them fell the brunt of the task. Mr. Collins was located in St. Paul, at the offices of the Great Northern and the Northern Pacific railways, with a corps of men under his direction. Mr. Gray was located in Portland, in the offices of the Oregon Railway & Navigation Company, with a similar corps.

To your honorable body I wish to express my sincere thanks for the many valuable suggestions that came from you as to the conduct of my appraisal. I wish it were possible for me to convey to the people of Washington my unbiased opinion of your honorable body. As a non-resident my opinion is unbiased. I believe you have shown great wisdom in not allowing yourselves to be hurried into action, for the sake of being able to point to "results." No ordinary citizen can realize the magnitude and the intricacy of the problem before you. It can become appalling only to one who has come face to face with it, and has delved into its details. So far as I know, you are the first state railway commission in America that has not allowed itself to be drawn into action on rate making before securing the fundamental facts that should govern such action. One of those fundamental facts is the physical value of the railways in the state. A physical valuation is absolutely essential, if for no other purpose than to determine a reasonable amount to set aside annually from earnings to cover the depreciation from natural agencies and from wear and tear. Tell me the physical value of a given structure, and I can estimate its depreciation in dollars closely. Conceal that value, and I am utterly in the dark. It has become the fashion to "poo-hoo" the necessity of a physical valuation of railways by commissions having rate-making powers. Even had the Supreme Court not ruled as to the necessity of a physical valuation, the necessity would exist, if for

no other reason than to solve the important problem of annual depreciation.

Original Cost and Cost of Production of the Great Northern Railway (768 Miles) in the State of Washington.*—This article will contain data that have not hitherto appeared in print. In fact the detailed, actual cost of construction of no large mileage of American railway has ever before been published, so far as we know.

Two years ago the Railroad Commission of Washington conducted a hearing at which the data collected by the Chief Engineer of the Commission, Mr. Halbert P. Gillette, were put in evidence, together with testimony as to the methods used in securing the data. Mr. Gillette subsequently condensed his testimony, as to sources of information and general methods used, into a brief report which formed part of the annual report of the Commission, and was reprinted in *Engineering-Contracting*, April 7, 1909. It was obviously impracticable to print in the report the mass of typewritten statistics forming Mr. Gillette's exhibits, so the Commission wisely printed only the results of its "findings" after listening to testimony submitted by the railways.

The gathering of the data kept a corps of some 20 engineers and land experts busy for a year in the office and in the field. Many of the data are of a character meriting publicity. We have, therefore, selected the most important parts from Mr. Gillette's exhibits and testimony, and will publish them. The first installment is in the present article and relates to the Great Northern Railway.

The major portion of this road in Washington was built, as a single-track line, in the years 1891 to 1894. It was built by contract at reasonable prices, and, in spite of the fact, that a rugged range of mountains was crossed, the original cost of 488 miles of line was only \$21,673,780, as shown by the accounting records, or \$44,400 per mile, including right of way and all costs except rolling stock. As will be noted below, the item of engineering was 3% of the total cost.

While the accounting records of the Great Northern did not comply precisely with the requirements of the Interstate Commerce Commission, still the departures were few—and for the best—so the items, as given below, are practically self-explanatory.

The section of line whose costs follow embraces the line as originally built (not including subsequent additions and improvements) from the Idaho-Washington boundary to Everett, from Seattle to Belfast, and from Anacortes to Rockport, a total distance of 487.6 miles. The original cost of this mileage was as shown in Table VI.

**Engineering-Contracting*, Dec. 3, 1909.

TABLE VI.—ORIGINAL COST OF 488 MILES OF GREAT NORTHERN RAILWAY LINE IN WASHINGTON.

Item.	Total.	Per Mile of Line or Roadbed.
1. Engineering	\$ 643,513.39	\$ 1,319
2. Right of way	1,978,874.53	4,066
3. Real estate	112,064.64	230
4. Clearing and grubbing	536,157.05	1,098
5. Grading	5,534,879.90	11,343
6. Tunnels	2,744,686.14	5,624
7. Masonry	459,436.06	942
8. Cribbing and bulkheading	348,287.42	714
9. Bridges and culverts	2,106,876.45	4,318
10. Cattle guards, road crossings and signs	114,274.79	234
11. Ties	584,464.37	1,198
12. Rails	2,894,548.33	6,032
13. Rail fastenings	377,508.94	774
14. Frogs, switches, etc.	82,423.78	169
15. Tracklaying and surfacing	259,006.76	532
16. Ballasting	630,482.41	1,088
17. Surfacing, filling and lining track ..	80,256.90	61
18. Transportation dept. buildings	800,141.08	616
19. Road dept. bldgs.	42,294.71	88
20. Roundhouses and shops	159,716.46	328
21. Fuel and water stations	125,811.22	263
22. Docks, wharves and inclines	21,476.67	44
23. Columbia River incline	59,485.91	122
24. Other buildings and structures	12,136.70	26
25. Fences	11,219.03	23
26. Telegraph	22,921.68	47
27. Shop tools and machinery	47,233.90	96
28. Protection against snow and ice	77,187.95	158
29. Locomotive and car service	42,287.03	86
30. General expense	52,854.13	108
31. Transportation men and materials	45,065.31	92
32. Insurance	549.90	1
33. Operating expense	251,323.52	514
34. Interest on advances	244,442.96	501
35. Bond expenses	36,065.80	74
36. Bond interest during constr.	766,139.99	1,569
37. Wagon roads	15,778.78	32
Total	\$21,672,873.67	\$44,412

There were 488 miles of railway line, or roadbed, and the side tracks, etc., amounted to about 8% additional; so that the costs per "mile of line" in Table VI should be divided by 1.08 to arrive at the costs per "mile of track."

Three items in Table VI bring out very clearly the rough character of the country, namely, items 5, 6 and 9. The Cascade Tunnel comprised almost the whole of item 6, the actual cost of that tunnel being \$2,524,212, including masonry lining.

The original grading quantities and classification were as given in Table VII.

The part of the Idaho Division that lies within the state of Washington was 48.77 miles long. The Washington Division extended to the foot of the "switchback" line, which was called the "Overhead Line," over the Cascade Mountains. The "switchback" was subsequently abandoned in part when the tunnel was com-

TABLE VII.—GRADING QUANTITIES.

Division.	Idaho.	Wash'ton.	Overhead.	Pacific.	B. & M.	S. & M.	Total.
Miles of line, or roadbed.....	48.77	227.08	11.70	74.46	75.31	54.43	491.78
Earth excav. within 300 ft. (cu. yds.)	227,986	515,673	3,346	248,891	431,323	379,408	1,806,613
Earth excav. within 1,000 ft. (cu. yds.)	324,149	478,675	149,248	256,060	76,008	1,279,133
Cemented gravel (cu. yds.).....	153,002	1,242,834	112,607	635,531	430,833	243,809	2,815,605
Loose rock (cu. yds.).....	66,242	360,135	49,658	268,191	39	7,006	739,221
Solid rock (cu. yds.).....	193,252	931,899	77,146	824,898	262	43,753	2,071,070
Embankment (cu. yds.).....	429,193	1,364,107	2,879	693,651	781,226	3,771,055
Unclassified (cu. yds.).....	299,856	299,856
Total.....	1,393,304	5,338,323	245,536	2,808,208	1,899,349	1,048,850	12,735,670
Overhaul, cu. yds., 100 ft.....	4,446,438	258,353	78,007	714,706	193,079	5,786,473
Clearing, acres.....	509	756	167	952	831	332	2,647
Grubbing, stations.....	1,033	1,213	584	2,370	1,770	983	7,334
Cu. yds. excav. and embank., per mile.	28,606	23,700	20,900	27,700	26,300	19,300	36,000

pleted. The Seattle and Montana (S. & M.) extended along Puget Sound from Seattle to Belfast. The Seattle and Northern (S. & N.) extended from Anacortes to Sauk.

The contract prices were quite uniform, and were about as follows per cubic yard:

Earth excav. hauled less than 300 ft.....	\$0.17
Earth excav. hauled 300 to 1,000 ft.....	0.21
Cemented gravel hauled less than 1,000 ft.....	0.38
Loose rock	0.42
Solid rock	1.06
Embankment from borrow pits.....	0.17
Overhaul, for each 100 ft. beyond the free haul of 1,000 ft.	0.01

Grading was paid for but once.

It is interesting to note that the average grading was 26,000 cu. yds. per mile, classified as follows:

	Per cent.
Earth excav. within 300 ft.....	14.4
Earth excav. within 1,000 ft.....	10.3
Cemented gravel	22.6
Loose rock	5.9
Solid rock	16.6
Embankment from borrow pits.....	30.2
Total	100.0

There was less than 50 ft. of overhaul on the average cubic yard of excavation, or less than $\frac{1}{2}$ ct. per cu. yd. for overhaul.

The average cost of grading, including overhaul, was about 40 cts. per cu. yd. of all excavation.

The price of clearing ranged from \$28 an acre in the Idaho Division to \$139 in the Pacific Division. Grubbing ranged from \$14 a station in the Idaho Division to \$25 a station in the Pacific Division.

The price of tracklaying was about \$230 per mile and the price of surfacing was about \$200 per mile.

Items 29, 30 and 31 are especially interesting in view of the absurd testimony that has often been given as to these items.

Item 33, Operating Expense, is the cost of operating trains over the line prior to its being turned over to the operating department.

Items 34, 35 and 36, total \$2,144 per mile, or about 4.8% of the total cost, which shows that an allowance of 5% for interest during construction is ample, although it has been frequently claimed that double this amount should be allowed.

A short line was built in northwestern Washington, from Bellingham northward and southward, called the Fairhaven Southern Ry. Part of it was subsequently abandoned. The remaining part was 32.3 miles long. Its cost was determined from the accounting records of its original builders, to which was added the costs shown in the Great Northern Ry. after it had passed into the latter's hands. This total cost for the 32.3 miles of line was as given in Table VIII.

TABLE VIII.—COST OF FAIRHAVEN SOUTHERN RY. (32.3 MILES OF LINE OR ROADBED).

Item.	Per mile of line.
1. Engineering	\$ 749
2. Right of way.....	2,230
3. Real estate	84
4. Clearing and grubbing (very heavy).....	1,083
5. Grading	4,012
6. Masonry	436
7. Cribbing and bulkheading.....	248
8. Bridges and culverts	4,196
9. Cattle guards and signs.....	7
10. Ties	761
11. Rails	4,303
12. Rail fastenings	493
13. Frogs, switches, etc.....	16
14. Tracklaying and surfacing.....	396
15. Ballasting	652
16. Transportation department buildings.....	545
17. Road department buildings.....	149
18. Roundhouses and shops	163
19. Fuel and water stations.....	273
20. Other buildings and structures.....	257
21. Fences	121
22. Telegraph	211
23. Shop tools and machinery.....	239
24. Locomotive and car service.....	189
25. General expense	748
26. Insurance	12
Grand total	\$22,566

The following were the grading quantities per mile and contract prices on the Fairhaven Southern:

9,200 cu. yds. earth, at \$0.21.
 2,000 cu. yds. cement gravel, at \$0.36.
 400 cu. yds. loose rock, at \$0.40.
 1,300 cu. yds. solid rock, at \$1.02.

12,900 cu. yds. total per mile.
 4,800 cu. yds. overhauled 100 ft., at \$0.01.

This is fairly typical of the yardage per mile of branch line built through "easy country."

Item 14, tracklaying, does not include train service, which is given in Item 24 for the entire construction of the road and is not prorated to the other items.

No interest was charged on the books.

The Spokane Falls and Northern Ry. was also built in the early 90's, by an independent company, whose cost records could not be secured. A field survey was accordingly made, and its cost was estimated, using prices that were common at the time of the construction of the line. This line is 130.5 miles long, and its original construction cost was estimated to have been as given in Table IX.

TABLE IX.—ESTIMATED ORIGINAL COST OF THE SPOKANE FALLS AND NORTHERN RY. (130.5 MILES OF LINE OR ROADBED).

Item.	Per mile of line.
1. Engineering	\$ 524
2. Grading	5,122
3. Bridges and culverts.....	1,164
4. Cattle guards and signs.....	24
5. Ties	1,612
6. Rails	4,931
7. Rail fastenings	791
8. Frogs, switches, etc.....	70
9. Tracklaying and surfacing (\$700 per mile of track)....	835
10. Ballasting	600
11. Transportation department buildings.....	396
12. Road department buildings.....	107
13. Fuel and water stations.....	147
14. Other buildings and structures.....	14
15. Fences	63
16. General expense	150
17. Bond interest during construction.....	785
Grand total	<u>\$16,445</u>

In addition to the 130.5 miles of line there were 20.79 miles of sidetracks, etc.

It will be noted that no land is included in this estimate, but \$1,000 per mile of line was the estimated value of the land in 1906. It was certainly much less originally. This line was probably built for \$17,000 per mile, including all land.

The Great Northern Ry. had just completed in 1906 a stretch of branch line in northern Washington, known as the Washington & Great Northern Ry. The completed portion was 83.9 miles long, through a mountainous country. The grading yardage per mile of line, and contract prices, were as follows:

9,200 cu. yds. earth excav. under 300 ft., at \$0.18
5,600 cu. yds. earth excav. under 1,000 ft., at \$0.22
9,000 cu. yds. cement gravel, under 1,000 ft., at \$0.35
1,800 cu. yds. loose rock under 1,000 ft., at \$0.40
6,900 cu. yds. solid rock under 1,000 ft., at \$0.93

\$2,500 cu. yds. total per mile
19,000 cu. yds. overhauled 100 ft., at \$0.01

The actual cost of this line was as given in Table X.

TABLE X.—ORIGINAL COST OF THE WASHINGTON AND GREAT NORTHERN RY. (83.9 MILES OF LINE OR ROADBED).

Item.	Per mile of line.
1. Engineering	\$ 1,489
2. Right of way.....	1,064
3. Real estate	3
4. Clearing and grubbing.....	656
5. Grading	14,558
6. Tunnels	75
7. Masonry	923
8. Bridges and culverts.....	3,623
9. Cattle guards, road crossings and signs.....	17
10. Ties	1,035
11. Rails	5,261
12. Rail fastenings	700
13. Frogs, switches, etc.....	161
14. Tracklaying and surfacing.....	866
15. Ballasting	1,024
16. Surfacing, filling and lining track.....	34
17. Transportation department buildings.....	139
18. Road department buildings.....	123
19. Roundhouses and shops.....	22
20. Fuel and water stations.....	389
21. Other buildings and structures.....	5
22. Fences	50
23. Telegraph	127
24. Locomotive and car service.....	575
25. General expense	25
26. Transportation of men and materials.....	2,378
27. Insurance	2
28. Operating expense	19
29. Interest on advances.....	1,099
30. Taxes	56
31. Wagon roads	17
Grand total	\$36,519

In addition to the 83.9 miles of line there were 7.89 miles of sidetracks, etc., whose cost is included above.

It will be noted that Item 1, Engineering, cost about 4% of the total; and that Item 29, Interest During Construction, was about 3% of the total.

In addition to the foregoing lines belonging to the Great Northern there was a short line, The Columbia & Red Mountain, 7.5 miles long, whose original cost could not be ascertained, but was estimated to have been \$258,327, or \$34,450 per mile.

The preceding costs total as follows:

Main line (487.6 miles).....	\$21,673,780
Fairhaven & Southern (32.3 miles)....	728,976
Washington & G. N. (83.9 miles).....	3,054,042
Spokane Falls & N. (130.5 miles).....	2,145,582
Columbia & Red Mt. (7.5 miles).....	258,327
Total original cost.....	\$27,860,807

If we allow \$140,000 for the probable cost of the right of way of the S. F. & N., we have \$28,000,000, in round numbers, for 742 miles

of line, or \$37,750 per mile, not including rolling stock. This is very close to the actual original cost.

We come now to the additions and improvements made since the original lines were built. They total as follows:

Fairhaven cut-off line (18.4 miles).....	\$ 962,102
New side tracks	747,209
Right of way.....	745,370
Real estate	2,619,513
Grading (mostly bank widening).....	1,142,369
Tunnels	1,250,145
Masonry	729,409
Cribbing and bulkheading.....	19,457
Bridges and culverts.....	465,520
Rails	52,207
Transportation department buildings.....	503,968
Road department buildings.....	50,541
Roundhouses and shops.....	90,332
Fuel and water stations.....	49,334
Grain elevators, coal bunkers, etc.....	104,933
Docks and wharves.....	546,926
Other buildings and structures.....	177,450
Fences	29,523
Telegraph	6,884
Shop tools and machinery.....	96,136
Protection against snow and ice..	111,501

Total additions and improvements.....\$10,410,859

This brings the cost up to June 30, 1906.

Unfortunately the account of New Sidetracks does not distribute the cost between the various items, as it should; consequently Mr. Gillette adopted the following distribution:

	Per cent.
Grading	25
Ties	10
Rails	40
Rail fastenings	10
Frogs and switches.....	10
Laying and surfacing.....	5
Total	100

In this manner the total itemized cost (original plus additions and improvements) was arrived at very closely, as shown in Table XI.

Table XI includes no allowance for the right of way of the S. F. & N. and of the Columbia & Red Mountain; but, as the present value of that right of way is only \$139,678, it will be seen that the grand total cost was about \$38,400,000.

In using Table XI the reader should be cautioned that the Additions and Improvements were not recorded in the accounting department exactly under the same headings as were the original construction costs. It was an error not to have done so, but it is the common practice of railway companies to make this mistake. Engineering, for example, is not recorded as a separate item in the Additions and Improvements (except on the "Fairhaven Cut-Off

Line," where it was 3% of the total); hence one cannot estimate the total cost of engineering on any part of the Great Northern work other than the original construction.

The same holds true of Locomotive and Car Service, Transportation of Man and Materials, and Interest during the time that work is in progress.

TABLE XI.—ORIGINAL COST OF GREAT NORTHERN RY., PLUS ADDITIONS AND IMPROVEMENTS UP TO JUNE 30, 1906 (767.76 MILES OF RAILWAY LINE AND 187.08 MILES OF SIDE TRACK AND OTHER TRACK).

Item.	Total.	Per mile of line.
1. Engineering	\$ 897,523.19	\$ 1,169*
2. Right of way	2,885,290.66	3,769
3. Real estate	2,834,533.12	3,632
4. Clearing and grubbing	657,585.67	856
5. Grading	9,561,212.68	12,454
6. Tunnels	4,166,137.81	5,426
7. Masonry	1,280,582.94	1,668
8. Cribbing and bulkheading	375,779.13	483
9. Bridges and culverts	3,275,111.79	4,266
10. Cattle guards, road crossings and signs	119,026.15	155
11. Ties	1,004,558.12	1,309
12. Rails	4,425,000.32	5,763
13. Rail fastenings	642,684.77	837
14. Frogs, switches, etc.	186,760.15	243
15. Tracklaying and surfacing	505,533.96	658
16. Ballasting	760,517.23	990
17. Surfacing, filling and lining track	34,095.90	44
18. Transportation department buildings	685,130.98	1,153
19. Road department buildings	122,739.89	160
20. Roundhouses and shops	256,933.73	334
21. Fuel and water stations	235,045.35	306
22. Grain elevators, coal bunkers and stock yards	104,932.89	136
23. Docks, wharves and inclines	627,888.57	817
24. Other buildings and structures	200,984.65	261
25. Fences	66,975.87	87
26. Telegraph	47,185.27	61
27. Shop tools and machinery	151,066.94	196
28. Protection against snow and ice	188,688.99	245
29. Locomotive and car service	96,536.47	126*
30. General expense	101,109.98	132*
31. Transportation men and materials	248,360.20	318*
32. Insurance	1,117.43	1*
33. Operating expense	252,948.43	329†
34. Interest on advances	336,342.11	437*
35. Bond expenses	26,065.80	47*
36. Bond interest during construction	880,835.66	1,146*
37. Taxes	4,696.89	6
38. Wagon roads	17,198.97	22
Total	\$38,270,760.56	\$49,848
39. Equipment (rolling stock)	3,973,586.18	5,176
Grand total	\$42,244,346.73	\$55,024

*These items relate only to original construction, and not to any of the work done under additions and improvements.

†Operating expense covers the cost of operating passenger and freight trains during construction (before the road was turned over to the operating department). This expense should really not be regarded as part of the cost of construction.

Since there were 0.244 miles of sidetrack and other tracks per mile of line, the costs in the last column of Table XI must be divided by 1.244 to arrive at the cost per mile of track. Multiplying by 0.8 will give almost the same result as dividing by 1.244.

Item 15 does not include all the surfacing, as will be seen by noting Item 17; but Item 15 includes locomotive and car service. The locomotive and car service of Item 29 relates to other work.

From the records of quantities in the engineering department of the Great Northern, supplemented by data in the accounting department, and by field surveys where necessary, Mr. Gillette prepared the estimated cost of reproducing (new) the Great Northern lines in the state of Washington, as detailed in Table XII. Item 2 (lands) in Table XII is based upon the final "findings" of the Washington Railroad Commission.

TABLE XII—ESTIMATE OF THE COST OF REPRODUCING THE GREAT NORTHERN RY. IN WASHINGTON, UP TO JUNE 30, 1906.
(767.75 MILES OF LINE AND 187.06 MILES OF
SIDE TRACKS AND YARD TRACKS.)

1. Engineering, 3 1/2 % of items 3 to 26 inclusive....	\$ 1,077,601.47
2. Right of way, etc.	
Terminal land, Seattle.....	\$10,937,543.69
Terminal land, Spokane.....	1,562,228.33
Terminal land, Everett.....	1,077,750.00
Terminal land, Bellingham.....	552,810.00
Right of way, and other station grounds.....	2,975,580.02
Total right of way, etc.....	\$17,105,892.04
3. Clearing and Grubbing.	
Clearing, 4,968 acres at \$100.00.....	\$ 496,800.00
Grubbing, 9,521 stations at \$20.00.....	190,420.00
Cutting dangerous trees, 6,596 at \$2.00.....	13,192.00
Total clearing and grubbing.....	\$ 700,412.00
4. Grading.	
Earth excavation (300 ft. haul), 2,802,452 cu. yds. at \$0.20.....	\$ 560,490.40
Earth excavation (1,000 ft. haul), 2,911,918 cu. yds. at \$0.25.....	977,979.50
Cement gravel, 2,998,152 cu. yds. at \$0.40.....	1,599,260.80
Loose rock, 1,186,985 cu. yds. at \$0.50.....	593,492.50
Solid rock, 3,246,964 cu. yds. at \$1.10.....	3,571,660.40
Unclassified excavation, 299,866 cu. yds. at \$0.50.....	149,933.00
Embankment, 2,771,056 cu. yds. at \$0.20.....	754,211.20
Overhaul, cu. yds. hauled 100 ft., 8,361,136, at \$0.01.....	83,611.36
Widening roadbed (acctg. records).....	1,142,368.85
Grading new side tracks (acctg. records).....	166,802.19
Total grading (except trestles filled, item 8).....	\$ 9,619,510.90

5. Tunnels.

Cascade tunnel (masonry lined), 12,812 lin. ft. at \$180.00.....	\$ 2,456,240.00
Everett tunnel (in earth, timber lined), 2,259 lin. ft. at \$60.00.....	135,540.00
Seattle tunnel (double track, in earth, masonry lined, $\frac{1}{2}$ owned by G. N.), 5,141 lin. ft. at $\frac{1}{2}$ of \$360.00.....	1,232,340.00
Other tunnels, 5,316 lin. ft. at \$75.00.....	398,700.00
W. & G. N. tunnel, 112 lin. ft. at \$60.00.....	6,720.00
Total tunnels.....	\$ 4,262,290.00

6. Masonry.

Riprap, slope wall and retaining wall (as per acctg. records, after deducting bridge and culvert masonry).....	\$ 345,712.94
7. Cribbing and Bulkheading. As per accounting records.....	\$ 375,779.12
8. Bridges and Culverts. Trestles (av. 18 ft. high, 20,390,311 ft. B. M. at \$30.00, and 1,234,583 lin. ft. piles at \$0.25), 128,400 lin. ft. at \$10.00.....	\$ 1,284,000.00
Trestles filled, 2,048,038 cu. yds. at \$0.20.....	409,607.60
Howe Truss and Combination Bridges (8,946 ft.). Spans under 60 ft., 968 lin. ft. at \$30.00.....	28,950.00
Spans 60 to 100 ft., 826 lin. ft. at \$35.00.....	28,875.00
Spans 100 to 150 ft., 3,909 lin. ft. at \$45.00.....	175,905.00
Spans over 150 ft., 2,346 lin. ft. at \$60.00.....	140,760.00
Steel Bridges (11,722 lin. ft.). Steel in place, 24,004,240 lbs. at \$0.0475.....	\$ 1,140,202.25
Foundation masonry, 20,267 cu. yds. at \$12.00	263,204.00
Log Culverts (31,606 lin. ft. culvert). Logs in place, 538,741 lin. ft. at \$0.16.....	\$6,198.56
Timber Culverts (12,922 lin. ft. culvert). Timber, 2,180,232 ft. B. M., at \$25.00.....	\$6,456.03
Box Drains (3,709 lin. ft. drains). Timber, 62,080 ft. B. M., at \$25.00.....	1,614.00
Concrete Culverts (2,377 lin. ft. culverts). Concrete, 4,740 cu. yds., at \$9.00.....	\$1,650.00
Stone Box Culverts (3,206 lin. ft. culverts). Masonry, 4,074 cu. yds., at \$5.00.....	20,370.00
Vitrified Pipe Culverts (11,870 lin. ft. culverts). 12-in. pipe, 694 lin. ft., at \$0.50.....	\$347.00
18-in. pipe, 2,848 lin. ft., at \$1.20.....	3,417.60
24-in. pipe, 4,058 lin. ft., at \$2.40.....	10,550.40
27-in. pipe, 3,583 lin. ft., at \$3.00.....	10,749.00
30-in. pipe, 687 lin. ft., at \$3.50.....	2,404.50
Cast Iron Pipe Culverts (6,159 lin. ft. culverts). 8-in. pipe, 48 lin. ft., at \$1.50.....	72.00
12-in. pipe, 606 lin. ft., at \$2.00.....	1,212.00
18-in. pipe, 852 lin. ft., at \$4.00.....	3,408.00
24-in. pipe, 2,119 lin. ft., at \$8.00.....	18,714.00
30-in. pipe, 1,324 lin. ft., at \$7.00.....	9,268.00
36-in. pipe, 210 lin. ft., at \$9.00.....	1,890.00
Total bridges and culverts.....	\$ 3,650,982.21

9. Ties.

Total of items 1 to 29, inclusive	\$51,249,402.44
30. Equipment.	
Locomotives	\$ 1,334,740.70
Passenger cars	715,896.82
Freight cars	2,320,036.29
Work and miscellaneous	198,451.19
Total equipment	\$ 4,569,124.80
Grand total of items 1 to 30	\$55,818,527.24

Regarding Item 2 of Table XII, it should be said that the Railroad Commission did not include any land not needed in the immediate future for railway purposes. In the city of Seattle there was land, owned by the Great Northern, of the estimated value of \$9,097,490, which is not included in Item 2. In Spokane there was similar land of the value of \$221,750, and other leased lands (bringing \$16,000 yearly income), whose value was not determined.

The chief engineer of the Great Northern presented an estimate of the cost of reproduction far in excess of that of Mr. Gillette above given. The Railroad Commission finally determined that \$58,671,559 would be a fair cost of reproducing (new) the Great Northern lines in Washington, and that \$52,887,080 would be a fair "present value," or second-hand value, of all this property, including equipment.

The accounting and engineering records of the Great Northern had been so kept that the yardage of earth in widening roadbed (subsequent to original construction) and in building new side-tracks, could not be ascertained without an amount of labor that did not seem to be warranted.

Referring to the last two entries in Item 4 of Table XII, it will be seen that they total \$1,329,170, or about 14% of the total of Item 4. At an assumed cost of 20 cts. per cu. yd. for this bank widening, etc., there were about 664,600 cu. yds., which is equivalent to 865 cu. yds. per mile of line. Dividing the items of yardage in Item 4 by 768, the miles of line, we have the following:

	Cu. yds. per mile of line.
Earth excav. (300 ft. or less haul).....	3,640
Earth excav. (300 to 1,000 ft. haul).....	5,090
Cement gravel	5,200
Loose rock	1,540
Solid rock	4,280
Unclassified excavation	390
Embankment from borrow.....	4,910
<hr/> Total	25,000
Widening roadbed (earth).....	870
<hr/> Total	25,870
Filling trestles (see Item 8, Table IV).....	270
<hr/> Grand total	26,140

In Item 8 it will be seen that the trestles averaged 18 ft. high. This was ascertained by dividing the total sum of the profile areas of the trestles by their total length. Trestle filling was kept in Item 8, in order to correspond with the accounting records.

The prices assigned to all classes of construction include all labor, materials and costs of transporting men and materials, train service, etc.

Item 12, Frogs and Switches, does not include cross-ties, which are included in Item 9.

Item 17, Telegraph Lines, was taken from the accounting records and 20% added to cover increase in prices, transportation of men, etc. The Great Northern does not own the telegraph lines entirely.

Table XIII summarizes the cost of reproduction, and gives also present value.

TABLE XIII.—COST OF REPRODUCTION AND PRESENT VALUE OF GREAT NORTHERN AS ESTIMATED BY H. P. GILLETTE.

	Reproduction. Condition.		Present Value.
	New.	Per cent.	
1. Engineering	\$ 1,077,601	100.0	\$ 1,077,601

28. Interest during constr.....	1,608,705	100.0	1,608,705
29. Stores on hand.....	360,904	100.0	360,904
Total of items 1 to 29....			\$51,219,402
30. Equipment	4,569,624	70.23	3,213,747
Grand total			\$55,819,026
			\$51,055,425

In arriving at an estimate of the Present Value, or second-hand value, of the property, Mr. Gillette determined the average age of each class of structures, as explained in his report to the Railroad Commission (see *Engineering-Contracting*, April 7, 1909). Then an annual depreciation was determined from a study of the records. For example, the average age of existing trestles was 4.2 years, and the annual depreciation was taken at 10%; hence the present addition was 100% — $4.2 \times 10\% = 58\%$.

Table XIV gives average ages and annual depreciations.

TABLE XIV.

	Age years.	Annual deprec. per cent.	Present condition per cent.
Cribbing and bulkheading.....	4.2	10.0	58.0
Howe truss bridges.....	5.0	10.0	50.0
Log culverts.....	9.4	6.0	41.8
Timber culverts.....	12.0	6.0	12.0
Box drains.....	12.0	4.0	12.0
Ties.....	4.3	12.5	46.2
Rails, track fastenings, etc.....	8.0	2.5	80.0
Fences.....	6.5	7.0	54.5
Transportation dept. bldgs.....	3.5	2.0	89.5
Road dept. bldgs.....	3.0	2.0	76.0
Roundhouses and shops.....	5.5	2.0	83.5
Fuel and water stations.....	80.0
Shop tools and machinery.....	3.5	10.0	65.0
Grain elevators.....	7.0	2.0	79.0
Docks and wharves.....	7.0	2.0	79.0
Other buildings.....	5.0	2.0	85.0
Snow sheds.....	6.0	4.0	72.4

The rate of depreciation of Fuel Stations was assumed at 3%; Water Stations at 2½%, the latter being lower because so much of the value exists in piping, reservoirs, etc.

Equipment depreciation was put at 3.6% per annum.

All other items were regarded as having suffered no depreciation. Grading was regarded as having actually appreciated 10% in value, due to the "seasoning" of the roadbed. This is equivalent to \$1,280 per mile, which was regarded as a liberal allowance for expenditures in track maintenance during the first few years after construction, which might properly be charged to construction, although, in fact, they never are so charged in the company books. It also provides for the increased value of the roadbed due natural settlement.

The actual cost of the equipment of the entire Great Northern Ry. system, as determined from the accounting records, was as follows, up to June 30, 1906:

Locomotives.....	\$10,020,193.14
Passenger cars.....	4,070,424.68
Freight cars.....	20,856,142.73
Work and miscellaneous.....	1,487,062.67
Total.....	\$35,933,823.22
Spokane Falls and Northern.....	190,742.00
Grand total.....	\$36,124,565.22

The actual original cost of the Spokane Falls & Northern equipment, as purchased by the Great Northern Ry., was not available, but was estimated to be \$190,742, composed of the following items:

Locomotives.....	\$ 71,500.00
Passenger cars.....	33,500.00
Freight cars.....	69,340.00
Work and miscellaneous.....	16,402.00
Total.....	\$190,742.00

To arrive at the cost of reproducing the equipment new, present (1906) prices, were assumed and applied to all the locomotives and cars. This showed an increase of cost of about 15%, hence it was decided to add 15% to the original cost (as shown by the accounting records) to obtain the cost of reproduction new.

With the exception of the locomotives, the entire equipment was then prorated to the state of Washington on the ratio of the car mileage of the entire system to the car mileage of Washington. The work equipment was prorated on the basis of the miles of road operated.

The cost of reproduction and the present value of the equipment for the state of Washington were estimated to be as follows:

	Cost of Reproduction	Present Value.
Locomotives	\$1,334,740.76	\$ 876,779.38
Passenger cars	715,395.92	494,404.42
Freight cars	2,320,036.29	1,635,410.98
Work and miscellaneous....	199,451.19	147,152.36
Total	\$4,569,624.10	\$3,213,747.09

The present value (second-hand value) was not ascertained by a field inspection, which is practically impossible of satisfactory accomplishment anyway, but by determining the average age of each kind of equipment and multiplying that age in years by 3.6% to arrive at the percentage of depreciation suffered.

Mr. Gillette's studies of the equipment records indicated to him that the average locomotive or car could not be expected to have a life exceeding 28 years, and that it would therefore be liberal to the railway to allow an annual depreciation of only 3.6% in arriving at the present value. He selected the straight line formula, rather than the sinking fund formula, for estimating depreciation.

In determining the average age of locomotives the standard price of each locomotive was multiplied by its age. The sum of these products was divided by the total cost of the locomotives to secure the average age. It would be manifestly incorrect to use the actual average age obtained by dividing the sum of the ages by the total number of locomotives, for locomotives differ so in value that the "weighted average" must be obtained. In like manner the age of all rolling stock was determined. It will be noted that there was an average depreciation of 29.67% (since the condition was 70.33%). Hence the average weighted age of all equipment was $29.67 \div 3.6 = 8.24$ years. The rolling stock on the Spokane Falls & Northern was all 10 years old, and on the rest it was as follows:

Locomotives	9.5 years
Passenger cars	8.5 "
Freight cars	7.4 "
Work and miscellaneous.....	7.0 "

The cost of reproduction of the Great Northern, per "mile of line," is given in Table XV.

TABLE XV.—COST OF REPRODUCTION OF GREAT NORTHERN RY. IN
WASHINGTON, AS ESTIMATED BY H. P. GILLETTE.

	Per mile of line.*
1. Engineering	\$ 1,406

Total of Items 1 to 29.....	\$66,753
30. Equipment	5,950
Grand total	\$72,703

*There are 1.244 miles of track per mile of line; hence multiply by 0.5 to get cost per mile of track.

During the fiscal year ending June 30, 1906, there were 479,-847,387 ton-miles of freight carried over the Great Northern within the state of Washington. The freight car mileage was 32,428,695 car-miles in Washington, or 9.681% of the car-mileage of the entire Great Northern system.

Cost of the Northern Pacific Railway (1,845 Miles) in the State of Washington.*—This issue contains data relating to the Northern Pacific Ry., data that were submitted as exhibits by Mr. H. P. Gillette in his testimony at the hearings before the Railroad Commission, but not printed in the "findings," which contain only the conclusions as to costs reached by the commission after hearing all the evidence.

Work was begun on the Northern Pacific in Washington in 1879, and the major part of the construction of the main line was done in the early 80's. The task of ascertaining the original cost of the Northern Pacific was complicated not only by the age of the rec-

*Engineering-Contracting, Jan. 12, 1910.

ords but by the purchase of a number of important branch lines. The purchase prices were available, but it was exceedingly desirable to arrive at the actual cost to the builders of those branches. This was determined with considerable accuracy by securing construction quantities from old engineering records and applying prices current at the time of construction. The total original cost of main line and branches in Washington was found to be about \$64,000,000, including improvements and betterments. Of this total 80% was ascertained with great accuracy from the accounting records. Of the remaining 20% fully half was determined with almost as great accuracy from old engineering records, leaving only about 10% to be estimated by field inspection.

It has been repeatedly stated that the original cost plus improvements can be ascertained for very few railways in America. Doubtless this assertion has deterred other railway commissions from even attempting to secure the original cost. The facts are, however, that of the entire railway values in Washington, not much more than 5% were such that the original cost plus improvements could not be found. Mere age of construction has less to do with the difficulty of arriving at original costs than is commonly supposed. The greatest difficulty exists where purchases of lines have been made without transfer of the construction ledgers from the original owners to the purchasers. In many instances such transfers of ledgers are made, and in nearly all cases transfers of cross section books and other engineering records are made. The importance of securing the original itemized costs plus itemized costs of improvements cannot be overestimated. The conflicting testimony of experts in court is the bane of a judge's life, but with actual original costs as a basis there is not great difficulty in determining costs of reproduction, for wages and prices are a matter of record and the increase or decrease in the value of any item of railroad construction is readily ascertained.

The following is a summary of the mileage of the Northern Pacific railway in Washington up to June 30, 1906:

	Miles.
Main line.....	653.73
Branch lines (incl. Wash. and Col. Rivers)...	986.53
Total lines.....	1,640.26
Second track, main line.....	41.65
Spurs.....	117.59
Yard tracks and sidings.....	400.75
Total track.....	2,200.25

In the findings of the Railroad Commission the following mileage was assigned to the Northern Pacific:

	Miles.
Main line.....	687.48
Branches and spurs.....	941.74
Total lines.....	1,629.22

However, we shall use the mileage determined by Mr. Gillette—namely: 1,645 miles of line—since the following costs are based upon that mileage.

The original cost of the Northern Pacific in Washington plus improvements and betterments up to June 30, 1906, as determined by Mr. Gillette, was as given in Table XVI. In using the last column of this table it should be remembered that there were 1.34 miles of all tracks to each "mile of line"; hence to arrive at the cost per mile of track, divide the items in the last column by 1.34.

TABLE XVI.—ORIGINAL COST OF THE NORTHERN PACIFIC RAILWAY IN WASHINGTON, PLUS IMPROVEMENTS.
(1,645 miles of line.)

	Total	Per mile.
1. Engineering	\$ 2,907,344.26	\$ 1,768

20. Fuel stations	79,544.48	47
21. Fencing right of way.....	273,067.50	166
22. Snow fences, etc.....	130,494.72	79
23. Stock yards.....	31,064.11	19
24. Crossings, cattle guards and signs.....	101,860.54	62
25. Interlocking and signal apparatus.....	44,706.61	27
26. Docks, wharves and coal bunkers.....	1,015,586.29	617
27. Transfer boats and barges.....	31,662.70	19
28. Section and tool houses.....	122,352.50	74
29. Miscellaneous structures	1,179,108.09	717
30. Telegraph lines	207,361.48	126
31. Transportation charges and rent of equipment	1,756,796.39	1,068
32. Operating expenses	261,910.26	159
33. Construction equipment	63,743.75	39
34. General expense	640,744.02	390
35. Interest and discount.....	7,173,190.53	4,360
36. Legal expense	3,009.24	2
37. Undistributed expense	480,212.62	292
Total	\$63,979,772.61	\$38,895
38. Equipment (rolling stock).....	11,478,121.23	6,978
Grand total	\$75,457,893.99	\$45,873

Of this \$63,979,772 cost of construction, \$5,396,735 was spent for "improvements and betterments" between the years 1896 and 1904. The corresponding improvement expenditures prior to that time (charged to "Construction B") were \$2,951,972, making a total of \$8,348,707 spent for improvements.

It will be noted that Item 1, Engineering, amounts to nearly 5% of the total cost exclusive of equipment. This very high percentage was due to several factors. The explorations for a pass through the Cascade Mountains were made at an early date when little was definitely known about their topography and that exploration alone cost \$300,000. The engineering on the early branch lines cost 4% of the \$11,400,000 spent in building them, due in part to slow progress of work in those early days. A very considerable part of the early Northern Pacific work was done by company labor, which added not only to the expenditures for engineering and supervision, but also made the entire cost of the work greater than it would have been had it been done by contract.

Items 2 and 3 are small, because nearly all the right of way was given by the government. But as a matter of fact it should be a trifle higher than given in Table XVI, to provide for the unascertainable original cost of right of way of about 350 miles of branch lines.

Item 31, Transportation Charges and Rent of Equipment, relates to the book charges for hauling construction materials over the N. P. lines. Under a proper system of accounting this item would have been distributed to the materials themselves.

Item 32, Operating Expense, relates to the cost of operating freight and passenger trains over the lines before they were formally transferred to the operating department.

Item 34, General Expense, was practically 1% of the total construction cost.

On the early construction work, involving some \$20,000,000, this item of general expense was nearly 1%.

Item 35, Interest and Discount, is inordinately high. It consists mostly of discount on the bonds. In fact the first \$22,400,000 expended, more than \$5,900,000 was charged to interest and discount, or nearly 27% of the total. Hence no general conclusions can be drawn from this item.

Item 36, Legal Expense, does not appear in any of the accounts except for a small branch line, where it amounted to nearly 1 per cent of the cost of that branch.

Item 37, Undistributed Expense, relates to certain items which were so entered that they could not be prorated to Washington under any definite item, and were consequently grouped here.

The cost of reproducing (new) the Northern Pacific Ry. in Washington, as estimated by Mr. Gillette, is given in Table XVII, the values of right of way and land being those finally determined by the Railroad Commission.

RAILWAYS.

1823

TABLE XVII.—COST OF REPRODUCING THE NORTHERN PACIFIC RAILWAY IN WASHINGTON, AS ESTIMATED BY H. P. GILLETTE.
(1,645 miles of line.)

1. Engineering, 5% of Items 3 to 27.....	\$ 2,510,580.23
2. Right of Way, etc.:	
Terminal land, Seattle	13,038,176.50
Terminal land, Tacoma	7,638,006.00
Terminal land, Spokane	5,308,486.00
Terminal land, Everett	366,530.00
Terminal land, Bellingham	215,330.00
Right of way and other station grounds.....	6,298,364.50
Total right of way, etc.....	\$ 32,862,872.00
3. Clearing and Grubbing:	
Clearing, 9,445 acres, at \$100.00.....	\$ 944,500.00
Grubbing, 16,542 stations, at \$22.00.....	330,840.00
Extra trees cut, 4,942, at \$2.00	9,884.00
Six branch lines (from acctg. records).....	117,811.04
Improvements (from acctg. records).....	24,069.48
Total clearing and grubbing.....	\$ 1,427,184.52
4. Grading:	
Earth excavation, 18,566,958 cu. yds., at \$0.22.....	\$ 4,084,730.76
Earth embank. (barrow), 3,265,120 cu. yds., at \$0.22.....	718,326.20
Unclassified, 318,612 cu. yds., at \$0.50.....	159,256.00
Cement gravel, 3,483,838 cu. yds., at \$0.40.....	1,393,535.20
Loose rock, 1,321,720 cu. yds., at \$0.50.....	660,860.00
Solid rock, 1,785,503 cu. yds., at \$1.10.....	1,909,053.30
Overhaul, 18,767,359 cu. yds. 100 ft., at \$0.01.....	187,673.59
Riprap, 186,064 cu. yds., at \$1.10.....	204,670.40
Slope wall, 3,350 cu. yds. at \$2.50.....	8,375.00
Log cribs, 882,632 lin. ft. logs, at \$0.16.....	141,221.12
Timber cribs, 127,774 ft. B. M., at \$28.00.....	3,522.12
Six branch lines (cost from acctg. records).....	1,113,697.75
S. L. S. & E. (estimated from field inspection)....	82,000.00
Improvements and betterments (from acctg. records).....	1,988,673.81
Total grading	\$ 12,543,325.25
5. Tunnels:	
Stampede, 9,844 lin. ft. (masonry lined), at \$180.00..	\$ 1,771,920.00
Seattle, one-half interest, 5,141 (dbl. track in earth), at 1/2 of \$360.00.....	925,380.00
Other tunnels lined with concrete, 2,570 ft., at \$110.00	282,700.00
Other tunnels lined with timber, 2,329 ft., at \$70.00..	163,030.00
Total tunnels	\$ 3,143,030.00
6. Bridges, Trestles and Culverts:	
Howe Trusses and Combination.	
20-ft. spans, 1 at \$1,200.00.....	\$ 1,200.00
50-ft. spans, 4 at \$1,600.00.....	6,400.00
60-ft. spans, 8 at \$1,800.00.....	14,400.00
70-ft. spans, 1 at \$2,000.00.....	2,000.00
80-ft. spans, 3 at \$2,300.00.....	6,900.00
90-ft. spans, 1 at \$3,000.00.....	3,000.00
100-ft. spans, 15 at \$4,000.00.....	60,000.00
110-ft. spans, 1 at \$4,500.00.....	4,500.00
120-ft. spans, 3 at \$5,500.00.....	16,500.00
130-ft. spans, 1 at \$6,200.00.....	6,200.00
140-ft. spans, 5 at \$7,000.00.....	35,000.00
150-ft. spans, 19 at \$7,500.00.....	142,500.00
13 miscellaneous spans (2,390 lin. ft. at \$60.00)....	143,400.00
8 draw spans, 1,625 lin. ft. at \$60.00.....	97,500.00
Total Howe trusses and combination spans....	\$ 539,500.00

Pile and frame trestles (44,130 M at \$30,000, and 1,304,533 lin. ft. piles at 0.25; av. height trestle 19 ft.), 168,978 lin. ft. at \$16.50.....	1,774,269.00
Trestles filled with earth (139,862 lin. ft.), 5,988,784 cu. yds. at \$0.20.....	1,197,756.80

Steel Bridges:

Spokane River at Trent.....	\$ 40,000.00
S Snake River, Ainsworth.....	1,100,000.00
Columbia River, Kennewick.....	500,000.00
Tacoma Channel.....	105,000.00
Chehalis River.....	100,000.00
Walla Walla River, W. & C. R.....	43,180.00
Three plate girders (260 ft.) and concrete ret. wall (350 ft.), N. & C. R.....	30,200.00
Steel in other bridges, 19,516,343 lbs. at 0.0475.....	927,026.44
Masonry abutments and piers for 215 spans.....	527,500.00

Total steel bridges.....\$ 3,282,916.44

Culverts:

Log culverts, 264,942 lin. ft. logs, at \$0.16.....	\$ 42,390.88
Timber culverts, 5,015,024 ft. B. M. at \$26.00.....	130,390.62
Box drains, 336,720 ft. B. M. at \$26.00.....	8,754.72

Total log and timber culverts.....	\$ 181,536.25
Concrete arch, 11,510 cu. yds. at \$9.00.....	103,590.00
Stone drains, 6,731 cu. yds. at \$8.00.....	53,848.00

Total masonry culverts.....\$ 157,438.00

Vitrified Pipe:

4-in., 62 lin. ft. at \$0.25.....	\$ 15.50
10-in., 50 lin. ft. at 0.45.....	22.50
12-in., 1,229 lin. ft. at 0.50.....	614.50
15-in., 226 lin. ft. at 0.75.....	169.50
16-in., 137 lin. ft. at 0.80.....	109.60
18-in., 8,929 lin. ft. at 1.30.....	5,107.70
20-in., 168 lin. ft. at 1.70.....	285.60
22-in., 109 lin. ft. at 2.00.....	218.00
24-in., 24,895 lin. ft. at 2.80.....	697,270.00
30-in., 2,846 lin. ft. at 3.50.....	9,961.50
36-in., 276 lin. ft. at 4.50.....	1,242.00

Total vitrified pipe culverts....\$ 682,469.40

Cast-Iron Pipe:

6-in., 300 lin. ft. at \$1.00.....	\$ 300.00
8-in., 24 lin. ft. at 1.50.....	36.00
12-in., 892 lin. ft. at 2.00.....	1,784.00
14-in., 27 lin. ft. at 3.50.....	94.50
16-in., 782 lin. ft. at 3.75.....	2,932.50
18-in., 5,095 lin. ft. at 4.00.....	20,380.00
20-in., 889 lin. ft. at 4.75.....	4,222.75
24-in., 28,411 lin. ft. at 6.00.....	170,466.00
30-in., 2,432 lin. ft. at 7.00.....	17,024.00
36-in., 4,453 lin. ft. at 9.00.....	40,122.00
42-in., 863 lin. ft. at 13.00.....	11,219.00
48-in., 1,028 lin. ft. at 18.00.....	18,504.00
54-in., 516 lin. ft. at 21.00.....	10,836.00
60-in., 198 lin. ft. at 25.00.....	4,950.00
36-in. corrugated iron, 900 ft. at \$3.00.....	2,700.00
Total iron pipe culverts.....	303,639.25
Masonry walls, etc.....	

Total bridges, trestles and culverts.....\$ 7,776,348.11

RAILWAYS.

1925

7. Ties:	
(2,205.24 miles at 3,000), 6,615,750, at \$0.50.....	\$ 3,307,875.00
8. Rails:	
221,367 tons at \$40.00.....	\$ 8,854,680.00

Turntables, 28 at \$2,800.00.....	78,400.00
6 ash pits, 277 lin. ft. at \$15.00.....	4,155.00
Total engine houses and turntables.....	\$ 237,819.50

uniform $3\frac{1}{2}\%$ for all the railways in the state as a fair allowance for engineering.

Item 2, Land, does not include any land not actually used or needed for railway purposes in the immediate future. The Northern Pacific Ry. has a right of way 400 ft. wide on much of its line, given to it by the government. The Railroad Commission allowed a 100 ft. strip as being all that is actually needed for railway purposes, except in towns and cities. In addition to the lands owned and used for terminals, there was land of the following value, which was not included in Item 2 because it is not needed for railway purposes at present:

Spokane	\$ 1,194,156
Tacoma	4,980,417
Seattle	9,250,000
Total	\$15,424,573

The value of the right of way land not needed for railway purposes was determined to be \$912,184, and is not included in Item 2. Item 4, Grading, is equivalent to the following yardage per mile of line:

	Cu. yds. per mile.
Earth excavation	11,325
Earth embankment (borrow)	1,990
Unclassified	195
Cement gravel	2,125
Loose rock	805
Solid rock	1,055
Total	17,495
6 branch lines (unclassified)	1,700
S. L. S. & R. (unclassified)	130
Improvements (unclassified)	4,545
Trestles filled (Item 8)	8,650
Grand total	26,520

The items of yardage in the "6 branch lines" and of yardage in "improvements" are estimated by assuming that the unclassified yardage on these branch lines cost 40 cts. per cu. yd. and that the yardage in improvements cost 20 cts. per cu. yd. Since most of the improvement yardage was bank widening, the lower unit price for this unclassified work is justified. By referring to our issue of Dec. 3 it will be seen that the yardage per mile on the Great Northern was 28,570 cu. yds. per mile.

Table XVIII gives a summary of Mr. Gillette's estimate of the cost of reproduction (new) and the present value (second hand) of the Northern Pacific in Washington. The annual rates of depreciation of the different classes of structures and of equipment were the same as those used in calculating the present value of the Great Northern.

TABLE XVIII.—COST OF REPRODUCTION AND PRESENT VALUE OF THE
NORTHERN PACIFIC RY. IN WASHINGTON.
(1,645 Miles.)

	Cost of reproduc- tion new.	Condition per cent.	Present value.
1. Engineering	\$ 2,510,580	100.0	\$ 2,510,580

30. Stores on hand	322
Total of Items 1 to 30	\$54,277
31. Equipment	8,715
Grand total	\$62,992

*There are 1.34 miles of track per mile of line.

The actual cost of the equipment on the entire Northern Pacific system, up to June 30, 1906, was as follows:

Locomotives	\$12,977,823.23
Passenger	5,074,739.99
Freight	21,436,740.43
Work and miscellaneous	1,904,185.11
Trust equipment	3,032,526.48
Discount and commission	939,858.42
Total equipment	\$45,365,882.66

The above does not include the equipment of the Washington and Columbia River Ry., which was estimated by Mr. Gillette to have cost as follows:

Locomotives	\$ 40,000
Passenger	24,000
Freight	62,000
Work	1,200
Total	\$147,200

The cost of the locomotives in Washington was based upon the cost of those actually used in that state. The cost of passenger and freight cars was apportioned to Washington according to car mileage. The cost of work equipment was apportioned according to mileage of railway line operated. On this basis the following costs were arrived at for the state of Washington:

	Original cost	Cost reproduction	Present value
Locomotives	\$,639,522	4,342,950	2,715,433
Passenger	1,598,184	1,447,692	863,556
Freight	5,665,564	2,040,288	5,668,220
Work and miscellaneous.....	624,851	602,579	425,522
Total	\$11,478,121	\$14,334,377	\$9,677,947

The "cost of reproduction" was determined by adding 15% to the original cost to provide for increased prices. The "present value" was determined by deducting from the "cost of reproduction" a depreciation of 3.6% per annum.

In this connection it is interesting to note that the report of the Northern Pacific Ry. to the Interstate Commerce Commission for the fiscal year ending June 30, 1906, gave the value of the equipment at \$32,044,260, or about 70% of its original cost. Mr. Gillette's estimate of the "present" value was 67.6% of the original cost, which shows that the Northern Pacific Ry. had charged off for depreciation only slightly less than Mr. Gillette has estimated.

It is also worthy of comment that many railway engineers have erred in their estimates of the cost of equipping railways, largely because they have taken the total cost of equipment given in the Interstate Commerce Reports and have divided it by the total mileage of railway lines. It has not been generally known that the costs given in the Interstate Commerce Commission reports are depreciated, or second hand, values.

In roughly estimating the probable cost of equipment of a steam railway line the proper method is obviously to base the estimate upon the ton-miles (or car-miles) of freight per year per mile of line. In *Engineering-Contracting*, June 19, 1907, the freight carried per mile of railway in America was shown to have been 530,000 ton-miles in 1904. Since the Northern Pacific carried 345,000 ton-miles in 1906 per mile of line in Washington, it may be regarded as nearly typical of the average American road, so far as freight is concerned. On the other hand, its passenger traffic is considerably less dense than that of the average American road. It is safe to say, therefore, that the cost of the equipment of the Northern Pacific is fairly typical of the average railway in America. Roughly speaking, then, the cost of equipment of an American railway is \$10 per 1,000 ton-miles carried per annum per mile of line.

During the fiscal year ending June 30, 1906, there were 1,390,044,447 ton-miles of freight carried over the Northern Pacific within the state of Washington, or 345,000 ton-miles per mile of line. This was almost 65% more per mile of line than was carried by the Great Northern, which accounts for the higher cost of the Northern Pacific equipment per mile of line.

In drawing conclusions relative to the probable average cost of railway lines throughout the country, serious errors have been made by considering only the costs in one or two states. It will be noted that the cost of terminal lands in Washington is enormous when charged entirely to the road mileage within that state. In the findings of the Washington Railroad Commission it was determined that 56.8% of the entire value of lands used by the whole Northern Pacific Ry. system exists in the state of Washington.

The Railroad Commission also determined that 62.3% of the entire cost of tunnels and 31.6% of the entire cost of bridges on the N. P. system is found in Washington.

These figures show clearly the rugged character of much of the country traversed by the N. P. in Washington. Unquestionably the cost of its lines in that state far exceeds the cost in any other state through which it passes. The same also is true of the Great Northern.

Cost of 500 Miles of the O. R. & N.—My appraisal of the Oregon Railroad and Navigation Co. lines in the state of Washington gave, briefly, the following results:

On June 30, 1907, there were 501 miles of single track main line and branches, and 88 miles of sidings and yard track. The construction period was from 1875 to 1899, but most of the mileage was built in the 80's.

The following was the original cost of construction per mile of single track main line and branches (501 miles):

	Per mile.
1. Engineering	\$ 623
2. Superintendence and inspection.....	73
3. Right of way.....	400
4. Lands and depot grounds.....	1,884
5. Grading	8,603
6. Clearing and grubbing.....	65
7. Tunnels	260
8. Bridges, trestles and culverts.....	2,518
9. Ties	1,397
10. Rails	5,589
11. Track fastenings	684
12. Frogs and switches.....	68
13. Ballast	526
14. Tracklaying and surfacing.....	798
15. Fencing, crossings, cattle guards and signs.....	113
16. Telegraph lines	4
17. Station buildings and fixtures.....	346
18. Section houses	141
19. Engine houses and shops.....	190
20. Turntables	50
21. Shop machinery and tools.....	10
22. Water stations	265
23. Miscellaneous structures	39
24. Legal expenses	6
25. Interest and discount.....	575
26. General expense	100
27. Taxes	8
28. Miscellaneous, undistributed..	581
Total original construction.....	\$22,931
Betterments, undistributed	2,388
Grand total	\$25,319

My estimate of the cost of reproduction new was as follows per mile of single track main line and branches (501 miles):

	Per mile.
1. Engineering (3¼% of Items 2 to 21).....	\$ 746
2. Grading	6,886
3. Tunnels	260
4. Bridges, trestles and culverts.....	2,782
5. Ties	1,666
6. Rails	4,515
7. Track fastenings	919
8. Frogs and switches.....	76
9. Ballast	721
10. Tracklaying and surfacing.....	928
11. Fencing right of way.....	258
12. Crossings, cattle guards and signs.....	44
13. Interlocking and signal apparatus.....	48
14. Telegraph lines	30
15. Station buildings and fixtures.....	282
16. Shops, roundhouses and turntables.....	165
17. Shop machinery and tools.....	46
18. Water stations	166
19. Fuel stations	52
20. Storage warehouses	113
21. Miscellaneous structures	397
22. Taxes	8
23. Section equipment	22
24. Legal and general expense (1% of Items to to 22)	202
25. Interest (5% of Items 1 to 24).....	1,065
26. Stores on hand.....	481
Total	\$22,635
27. Right of way and terminal grounds.....	4,487
Total	\$27,122
28. Equipment (rolling stock).....	2,994
Grand total	\$30,116

For a more detailed statement of the foregoing items, consult the files of *Engineering-Contracting*, year 1910.

Note that there were 68 miles of sidetracks in addition to the 501 miles of main line. Hence the above costs per mile of main line should be divided by 1.136 to ascertain the cost per mile of track.

Appraised Value of the Steam Railways of Wisconsin.*—In our issue of June 26, 1907, was published the appraised value of the railways of Wisconsin, as of June 30, 1903. The following is a brief summary of the last valuation, as of June 30, 1907, which was completed in December, 1908, under the direction of Prof. W. D. Pence, Engineer of the Wisconsin Tax Commission and of the Railroad Commission. Table I is a summary of the first and the last valuations.

**Engineering-Contracting*, Jan. 19, 1910.

TABLE XX.—COMPARISON BETWEEN FIRST AND FIFTH WISCONSIN
STREAM ROAD VALUATIONS.

	—Valuation as of date.—	
	June 30, 1903.	June 30, 1907.
Number of railroad properties included...	47	52
Total length, road mileage.....	6,656.83	7,090.39
Cost of reproduction:		
Property, new total.....	\$205,760,519	\$244,128,868
Cost of reproduction:		
Existing condition, total.....	169,758,518	186,239,314
Reproduction cost per mile of line:		
Property new	30,900	34,400
Present value per mile of line.....	25,500	27,700
Per cent condition.....	82.5	80.3
The mileage on June 30, 1907, was as follows:		
Main line		6,519.69
Main line, joint, $\frac{1}{2}$ interest.....		9.80
Branch line		551.83
Branch line, joint, $\frac{1}{2}$ interest.....		9.07
Total main and branch line.....		7,090.39
Second track		431.57
Third track		40.62
Fourth track		35.54
Total "trackway"		7,598.12
Spurs and sidings.....		2,523.83
Spurs and siding joint, $\frac{1}{2}$ interest.....		52.83
Spurs and sidings joint, $\frac{1}{2}$ interest.....		4.32
Spurs and siding joint, $\frac{1}{2}$ interest.....		0.29
Crossovers		0.04
Grand total track.....		10,178.93

The total appraised values, new and in present (depreciated) condition, as of June 30, 1907, are as in Table XXI.

TABLE XXI.—VALUATION NEW AND IN DEPRECIATED CONDITION OF
WISCONSIN RAILWAYS.

	Cost of reproduction.	
	New.	Present condition.
1. Right of way and station grounds....	\$ 26,339,419	\$ 26,339,419
2. Real estate		
3. Grading	39,391,807	39,391,807
4. Tunnels	797,412	776,972
5. Bridges, trestles and culverts.....	14,616,486	14,638,887
6. Cross ties and switch ties.....	11,181,399	5,826,021
7. Rails	30,111,358	24,605,740
8. Track fastenings.....	5,254,013	3,867,649
9. Frogs, switches and crossings.....	1,179,056	743,079
10. Ballast	5,768,084	3,969,476
11. Track laying and surfacing.....	3,345,555	2,770,572
12. Fencing	1,611,775	826,512
13. Crossings, cattle guards and signs....	440,896	269,880
14. Interlocking and signal apparatus....	613,854	538,801
15. Telegraph lines.....	167,840	99,587
16. Telephone lines and distribution system	89,639	81,439
17. Station buildings and fixtures.....	3,918,895	2,902,418
18. Shops and round houses, power houses and car barns.....	3,893,882	3,048,497
19. Tools	144,419	86,384
20. Water stations.....	1,345,218	986,357
21. Fuel stations.....	466,745	351,432
22. Grain elevators.....	326,706	612,171
23. Warehouses	262,539	200,278
24. Docks and wharves.....	3,645,907	2,956,821
25. Miscellaneous structures.....	2,106,101	1,409,949
26. Sub-stations	45,130	44,119
Totals of all the above items.....	\$161,562,235	\$136,893,767

27. Engineering, superintendence, and legal expenses, 4.5% of all the above items	7,270,300	6,160,220
28. Locomotives	11,631,174	7,331,573
29. Passenger equipment.....	5,317,465	3,193,301
30. Freight equipment.....	20,944,348	20,479,648
31. Miscellaneous equipment.....	901,935	588,260
32. Ferries and steamships.....
33. Electric plants.....	161,476	146,114
34. Shop machinery and tools.....	1,573,000	1,186,369
Totals of all the above items.....	\$219,261,932	\$176,979,252
35. Freight on construction material, 0.7% of items 1.34.....	1,523,656	1,209,539
36. Interest during construction, 3% ; Organization, ¹ , contingencies, 5.5% ; in all, ² , of items 1.34.....	20,738,226	16,463,297
37. Stores and supplies on hand for use in Wisconsin.....	2,606,054	2,587,226
Totals	\$244,128,868	\$196,239,314

¹1% and 1.5%.²9.5% and 10%.

Includes dock property and all lines under construction.

Dividing each of the items in the first column of Table XXI by 7,090, we have the following cost per mile of roadbed:

	Per mile of roadbed.
1. Right of way, etc.....	\$ 3,714
2. Real estate.....
3. Grading	5,554
4. Tunnels	112
5. Bridges, etc.....	2,625
6. Ties	1,577
7. Rails	4,246
8. Track fastenings.....	741
9. Frogs, etc.....	166
10. Ballast	813
11. Track laying and surfacing.....	472
12. Fencing	227
13. Crossings, etc.....	62
14. Interlocking and signal.....	96
15. Telegraph	24
16. Telephone	13
17. Station buildings.....	653
18. Shops and roundhouses.....	548
19. Tools	20
20. Water stations.....	189
21. Fuel stations	86
22. Grain elevators.....	121
23. Warehouses	37
24. Docks and wharves.....	514
25. Miscellaneous structures.....	297
26. Substations	6
Total of above.....	\$22,783

27. Engineering	1,025
28. Locomotives	1,625
29. Passenger equipment.....	750
30. Freight equipment.....	4,362
31. Miscellaneous equipment.....	127
32. Ferries, etc.....	...
33. Electric plants.....	22
34. Shop machinery and tools.....	222
Total of above.....	\$20,918
35. Freight on construction materials.....	215
36. Interest during construction, contingencies, etc.	2,924
37. Stores on hand.....	267
Grand total.....	\$24,424

Since there are 1.435 miles of track per mile of roadbed, each of the above items should be divided by 1.435 (or multiplied by 0.7) to obtain the cost per mile of track. For example, item 11, "Track laying and surfacing," is \$472 per mile of roadbed, which is equivalent to $0.7 \times \$472 = \331 per mile of track, which, by the way, is an exceedingly low estimate of cost.

Cost per Mile of Railways in Wisconsin and Michigan.*—In the year 1900, Prof. Mortimer E. Cooley made an appraisal of all the steam railways in Michigan for the Board of State Tax Commissioners. A field inspection was made of every structure to determine its "present value" expressed as a percentage of its value now. About 23,000 freight cars were inspected for the same purpose. By examining records of transfer of lands it was decided to use a factor of 2 to $2\frac{1}{2}$ by which to multiply the market value of adjacent property to obtain its "value for railway purposes." It is a well-known fact that a railway usually pays two to three times the ordinary market value of land in securing its right of way.

Prof. Cooley did not secure the "original cost" of the railways, that is, he did not secure the cost as determined by an inspection of the railways' records; but he made his own estimate of the "cost of reproduction" under the then (1900) existing conditions as to prices, wages, etc. An examination of his estimate leads us to think that it was, in many items, much too low, even though he added 10% for contingencies. But the railways have, as yet, not fought the estimate, because it was made for taxation purposes, and the lower the estimate the more to their liking.

The Wisconsin appraisal was made by Prof. W. D. Taylor for the State Board of Assessment. He began this work in June, 1903, and made his final report 18 months later. Prof. Taylor pursued much the same plan as that pursued by Prof. Cooley, except that he required the railways themselves to submit first their own estimates of the cost of reproduction, which he subsequently checked, adding $13\frac{1}{2}\%$ to their appraisal. Of course the railways tried to keep their estimates as low as possible, for the reasons above given, and it is quite apparent that the estimates were too low, even after Prof. Taylor had added the $5\frac{1}{2}\%$ for contingencies.

**Engineering-Contracting*, June 26, 1907.

TABLE XXII.—COST OF WISCONSIN AND MICHIGAN RAILWAYS.

Item.	—Cost of Reproduction—New.—		—Michigan.—		Present value expressed as per cent of cost of reproduction—new.
	Wisconsin.	Michigan.	Cost per mile of main line and branches (7,813 ml.) year 1903.	Cost per mile of main line and branches (7,813 ml.) year 1900.	Wis. Mich.

includes track tools—probably not.

Assumed at 4%, and legal expenses at 1 1/2% of items 2 to 25.

Now that the state of Wisconsin has begun to use the appraised values of the railways as a basis for rate making, the shoe is on the other foot, and it is not unlikely that the railways will ultimately demand a new appraisal, just as some of the railways in Texas have already done.

The appraised values of the Wisconsin and Michigan railways are given in the reports of Prof. Taylor and Prof. Cooley in such form as to admit of ready comparison. Table XXII is presented herewith in the belief that it may be of use to many of our readers.

The column showing the percentage of cost of each item is particularly interesting. It will be noted that grading cost only 16.5% in Wisconsin and 10.4% in Michigan. To the average engineer grading seems such a very important item that a knowledge of its real relative importance becomes very instructive. Grading in the more rugged state of Washington is far more expensive per mile than in the states of Wisconsin and Michigan. Indeed, there is scarcely an item of cost in Washington that will not exceed the costs given in the accompanying tables.

In using these tables the reader is cautioned to bear in mind the fact that the costs are expressed in the "mile of line" as the unit, and not in the "mile of track." There are practically 1.4 "miles of track" in each of the two states per "mile of line."

It will be noted that the "mile of line" is here used as synonymous with the "mile of roadbed."

Prof. W. D. Taylor used the following method in appraising the "present value" of steel rails in Wisconsin lines. If the market value of new rails is \$22 per ton, and the scrap value is \$12, then the wearing value is \$10. If inspection indicates that 40% of the life has been used up, the present condition of the rail is 60%, and its present value per ton is $\$12 + 60\% \text{ of } \$10 = \$21.50$ per ton.

Mr. Taylor adds, however, that another point of view might be taken. If the price of new rails at the mills in Chicago is \$22, and the scrap price at the mills is \$14, and if the rail is used at a point 200 miles from Chicago, then the cost of transportation is \$1 per ton. This would make the price of the new rail \$23 delivered, and would reduce the value of the scrap rail to \$13 at the place of removal. To lay the new rail would cost \$24.50 per ton, making a total of \$21.50 per ton in place. To take up and load the old rail would cost \$1 per ton, making the net realization from its sale in Chicago but \$12 per ton. In addition the old rail has lost 3 to 6% of its weight.

Mr. Taylor states that the Chicago and Northwestern Ry. expended \$11 per mile of roadbed in preparing the cost data for some 1,800 miles of its road. But he does not state what the state of Wisconsin spent in reviewing these data submitted by the railways.

In the appraisal of the Michigan railways the following unit prices were used:

Earth (incl. overhaul), per cu. yd.....	\$ 4.30
Rails, new, per ton.....	22.00
Rails, scrap, per ton.....	12.00
Rails wearing value per ton.....	16.00
Ties (16 to 17 per 30 ft. rail), oak, each.....	0.55

Life of trestles was considered to be 10 years.

Life of telephone poles and cross-arms, 12½ years.

Copper wire depreciation:

	Per cent.
For 3 years and less than 3 years.....	2½
For 3 years and less than 5 years.....	5
For 5 years and less than 10 years.....	10
For 10 years and over (junk value).....	20
Underground conduit, per year.....	3
Cable (aerial or underground), lead covered and rubber, per year.....	10
Switchboards, per year.....	10

It has been stated that the cost of appraising the Michigan railways was \$50,000, or \$6.40 per mile of roadbed; but the railways themselves spent an amount which is unknown.

Appraisal of the Railways of Minnesota.*—We had hoped to be able to present in this issue of *Engineering-Contracting* abstracts of the reports of the chief engineers of two railway commissions, namely the report of Mr. Dwight C. Morgan to the Railroad and Warehouse Commission of Minnesota and the report of Mr. Halbert P. Gillette to the Railroad Commission of Washington. Mr. Morgan's report was submitted Nov. 20, 1908, and has just been published. Mr. Gillette's report was submitted a year ago but its publication has been delayed.

The two reports present many interesting contrasts in methods used in attacking the same problem, and, for that reason as well as because they are the first appraisals ever made for railroad commissions as a basis for railroad rate making, it was desirable to present them simultaneously. However, there are so many of our readers who will be interested in the methods and data given in Mr. Morgan's report that we present a summary in this issue, as follows, condensing the explanations of methods into our own language.

Mr. Morgan began the appraisal of the Minnesota railways Jan. 15, 1906, and rendered his report Dec. 1, 1908, the work having occupied almost three years, during which time 7,536 miles of railways were appraised. The method of making the appraisal was essentially the same as that used by Mr. William D. Taylor, engineer of the Wisconsin Tax Commission, who made an appraisal of Wisconsin railways for taxation purposes.

This method is what might be called the co-operative method of appraisal, because the railway companies are asked to co-operate with the railway commission, and, indeed, are required to submit their own detailed estimate of costs to the commission. The theory is that the commission is thus saved much unnecessary labor, and has merely to check over the estimates of the railways. In practice, however, it is our opinion that the engineers of the railway commission must either accept the returns of the railways without

**Engineering-Contracting*, March 3, 1909.

question or else spend almost as much time and labor in checking the estimate as was originally made by the railways in preparing it.

Blank forms were furnished to all the railways, upon which they were required to enter their detailed estimates. Two estimates were required, one giving the "cost of reproducing the property new. The other giving the "present value of the physical properties." The "cost of reproduction" means the cost of reproducing the property new. The "present value" is the depreciated or second-hand value, ascertained by deducting depreciation from the "cost of reproduction."

The unit prices used by Mr. Morgan were the average prices for the year 1905, which, he states, were about an average of the prices for the five-year period ending June 30, 1907.

In estimating the various railway lines, sections of about 100 miles were taken, but the "terminal properties" in St. Paul, Minneapolis and Duluth were treated as separate sections.

In valuing the lands, Mr. Morgan did not wait for a report from the railways, but started an independent investigation at once. Special agents were appointed to ascertain the value of lands adjacent to all railway lines. These agents examined and noted more than 55,000 bona fide sales of property, involving considerations of \$100,000,000, and representing 1,300,000 acres of land. To do so they examined the records of the transfer of property for several years prior to Jan. 1, 1900, for a distance of $1\frac{1}{2}$ miles on each side of each railway line, using the official county records for information.

The figures thus ascertained were plotted on maps, which facilitated arriving at values per acre in any given section. This, in our judgment, was an excellent procedure, but it has a serious defect. No such records can be introduced in court, for the reason that records of property transfers are often falsified as to values by the parties engaged in the transfer. However, such data form an excellent guide to the judgment of the experts engaged in determining land values, particularly where the opinions of people differ widely as to such values.

Having ascertained the value of lands adjacent to the railways, the next step is to multiply these values by some factor to arrive at the value of land for "railway purposes." Mr. Morgan says, in his report:

"The purchase of lands for a railroad right-of-way requires the consideration of two elements: First, the fair value of the land taken, and, second, the damage to the residue in consequence of a part of the tract having been taken for railroad purposes. The element of damage is dependent upon a variety of conditions, several of which may be mentioned as, the location and direction of the proposed railroad with respect to the boundaries of the property; the inconveniences and dangers likely to be suffered and attributable to the construction and operation of the line, such as the separation of the owner's house from his barn, or of his barn from his well.

The influence of public opinion for or against the construction of a line of railway is a most potent factor in respect of cost. (If one railway already exists, a projected second railway nearby will have to pay much higher prices for land, due to the fact that land owners do not feel the necessity of a second road and will "hold up" the new railway for the highest possible prices.—Editor.) In varying degrees, these and other considerations make the lands purchased for a railway right-of-way usually more costly than the true or normal value of lands for other purposes."

Mr. Morgan goes on to say that his agents had examined the bona fide sales of lands to railway companies, covering the more recently constructed lines, involving 7,000 acres and an expenditure of \$4,200,000 in acquiring them in various parts of the state. As a result of this investigation and of a study of the whole subject, the conclusion was reached that a multiple of 3 should be used in converting the normal value of right-of-way lands to the "value for railway purposes." This multiple of 3 was not applicable to lands in the large terminals. St. Paul, Minneapolis and Duluth.

Mr. Morgan calls attention to an illuminating instance of the high cost of land acquired by condemnation as compared with the cost of land purchased by agreement. On the Illinois Central, in the counties of Mower and Freeborn, about 35% of the right-of-way was secured by condemnation proceedings and the company paid $4\frac{1}{2}$ times the normal value of the land. The remaining 65% purchased by agreement cost only 1.7 times the normal value of the land.

The multiples used in arriving at the values of terminal property for railway purposes were as follows: For St. Paul, 1.75; for Minneapolis, 1.60; for Duluth, 1.25. In other words, the normal value of the bare land (not including buildings) in St. Paul was multiplied by 1.75 to obtain the "value for railway purposes." These multiples were arrived at as follows: Investigations made (in 1906) by a special tax committee of the city council of St. Paul had shown that property was assessed at about 60% of its selling price. Hence the assessed value of property adjacent to the terminals in St. Paul was divided by 0.6 (or multiplied by 1.66) to arrive at its normal value. This normal value was then multiplied by 1.75 to arrive at its "value for railway purposes."

The multiples of 1.75 for St. Paul, 1.60 for Minneapolis and 1.25 for Duluth were based upon the purchases of real estate by railways in those cities during the preceding six years. During that period more than 320 acres of property had been purchased by railways for about \$3,000,000. Comparing the prices thus paid by railways with the prices paid by other corporations and individuals during the same period, the multiples above given were arrived at. Fortunately two railway companies had purchased land for terminals in St. Paul and one in Duluth during this six-year period, so that sufficient data were available to enable Mr. Morgan to arrive at a fair decision as to the multiples to be used.

An inspection of the physical property of the railway was made, practically all this inspection being done in a manner that will be

regarded as rather superficial by many of our readers. Each railway company provided a special train which carried the inspectors. "The train was moved at a low rate of speed so that observation could be had of the character and standards of construction and maintenance. Stops were made every mile, in places, but usually every two miles, and sometimes every five miles, to enable measurements of the roadbed and ballast, to observe the brand, weight and age of the rails and fastenings, to ascertain the average number of ties per mile by test measurements and counts; in fact, to make complete record of all the physical elements at these given points. Additional stops were frequently made at bridges and culverts for the purpose of measurement and inspection, and at all stations measurements of buildings were made, the inventories checked and notes made of any important changes.

"The detailed reports of the railway companies having been compiled on the forms prepared for that purpose, were in such systematic order by subjects as enabled the ready checking of the various items enumerated. The profiles were continually made use of to determine their accuracy. * * * Also as to whether sand, gravel, loose or solid rock cuttings, which would later serve as a guide in the classification of material in making the compilations and estimates of quantities in the office."

That this inspection was cursory is shown from the fact that about 100 miles of line were inspected each day of 16 hours from each train.

No inspection of rolling stock was made, as in the Wisconsin appraisal above referred to; but the "equipment reports were checked by the serial numbers of locomotives and cars."

The inspection was begun early in May, 1907, and continued almost without interruption until the middle of December, 1907, completing this feature of the work, "except the range roads, which were examined in the early part of 1908."

The unit prices assumed for estimating costs "are the results of much research." The unit prices submitted by the railways in their reports differed widely, and often in a manner not susceptible of explanation. For example, the price of steel rails varied from \$20 to \$31.50 per ton f. o. b. St. Paul; bridge steel of the same class ranged from 2½ to 4½ cts. per lb.; locomotives of the same type and weight varied from 6¾ to 12¾ cts. per lb.; engineering, superintendence and legal expense, between 1½ and 16%; interest during construction, 1 to 12%; contingencies, 5 to 50%.

Mr. Morgan selected unit prices to fit the local conditions and did not assume invariable unit prices for all roads, as was done in the Wisconsin appraisal.

"Adaptation and solidification of roadbed," or "seasoning of the roadbed," was regarded by Mr. Morgan "as a labor account covering a period of years," and treated as a separate item of cost, although it never appears in the records of any railroad company as a part of the cost of construction. According to the allowance made by Mr. Morgan, this item of "adaptation and solidification of road-

bed" amounted to \$11,743,000 for the 7,596 miles of railways in Minnesota, or \$1,545 per mile, or nearly 5% of the grand total cost of construction and equipment.

There is no doubt that the roadbed of a newly built railway requires more labor to maintain and that the cost of running trains of the roadbed is more expensive than after the embankments have settled and land slides and slips have become less frequent; but no two engineers will agree as to what allowance, if any, should be made for the cost of "seasoning." The fact is that much of this "seasoning" is due the action of rain, and costs nothing. Practically all the rest of it is done by the trackmen who are maintaining the track, as a part of operating expenses. The 7,600 miles of railways in Minnesota averaged 33,140 cu. yds. of earth, loose rock and solid rock. Hence, according to Mr. Morgan's estimate of \$1,545 per mile for "seasoning," it would have cost nearly 7 cts. per cu. yd. for "seasoning" alone. Since earth can be spread and rolled for only a fraction of this 7 cts. per cu. yd., it is evident that most of this \$1,545 item of "seasoning" must be due to some other class of work than grading. In giving his reasons for his seemingly large allowance for "adaptation and solidification of roadbed," Mr. Morgan says:

"The newly made excavations wash and slip, the ditches fill from the action of the elements, the embankments settle and the track superstructure is in almost constant need of attention; resurfacing, lining and dressing of ballasted and unballasted track is necessary, waterways become clogged up, bridges settle or go out of line, station grounds are to be improved and finished, scattered and unused material must be picked up and stored; in fact, all the loose ends which are the immediate sequence of construction must be gathered in and the property brought to an orderly condition."

While engineers will never agree as to the exact amount that should be allowed for "seasoning" of roadbed, still the majority would probably favor some allowance in estimating the cost of reproduction of an existing railway.

On the other hand, there will not be so many engineers who will favor any allowance for "contingencies" in estimating the cost of an existing railroad line. Mr. Morgan favors a small allowance for contingencies, and, as will be seen below, selected 5% as a fair estimate for this item, instead of the customary 10% used on estimates of projected lines. He says:

"Considering the detail with which the estimates have been prepared and the inclusion in them of many items of a contingent nature, it does not appear justifiable to consider an estimate of the cost of reproducing a railway as synonymous with an estimate for constructing a projected line. The essential difference rests in the fact that in reproduction cost the estimate is prepared in the light of known conditions, whereas for a projected line the contingencies are wholly unknown. These facts have been instrumental in reaching a determination that 5% for contingencies is fair under the circumstances attaching to the work of this appraisal."

In estimating the item of "interest during construction," Mr. Morgan assumed a rate of interest of 4% per annum on the money tied up during construction. "This rate of interest was applied to the total estimated cost of reproduction, assuming that the necessary funds would be fully employed one-half of the estimated time required to build the respective lines, which according to their mileage varied from 1 to 8 years." It will be seen from the data given below that this interest item amounted to about 2.2% of the total cost of reproduction as estimated for all the railways of the state.

The "present value" of each item was arrived at by deducting an estimated percentage of depreciation from the estimated "cost of reproduction." This estimated percentage of depreciation was furnished by hardly any of the railway companies, for they held that no real depreciation had occurred, and that a road is more valuable as a working tool years after its construction than when new. Mr. Morgan made his own estimates of depreciation, based upon the inspection above referred to, and thus arrived at the "present value" given below. It will be noted that the total "present value" is about 13% less than the "cost of reproduction."

Mr. Morgan did not secure the original cost of construction and betterments, and he states that such data were so incomplete as to render the task hopeless. He says that "for the older and more important railways, representing the greater part of the mileage of the state, the data for some of them is not available at all, and for others it is so incomplete as to render its development for practical use an impossibility."

We believe that Mr. Morgan is wrong in this conclusion, for in making the appraisal of the railways of Washington these same arguments were used by the railways, and it was only after a bitter struggle in some cases that access to all their records was secured which developed that practically all the costs of construction and betterments could be found, even for the lines built forty years ago. Among these Washington lines was the Great Northern, which has nearly 30% of the mileage in Minnesota. Its original records of cost (in the St. Paul office) are exceptionally well kept and complete, as well as its records of betterment costs. If only used as a guide in estimating the cost of reproduction, these original records (both in the accounting department and in the engineering department) are practically invaluable. Furthermore, they are of great value in cases of litigation between the railway commission and the railway company where the accuracy of estimates of cost of reproduction are brought into question.

Another point of great importance is the percentages allowed for contingencies, for interest during construction and for engineering. Mr. Morgan has allowed 5% for contingencies, nearly 2% for interest during construction, and 4% for engineering, superintendence and legal expense. Each of these percentages alone sounds small, but they aggregate more than \$61,000,000 in Mr. Morgan's estimate. So enormous is this sum that the correctness of these

percentage allowances becomes a very important matter to the railway companies and to the state. We know of no satisfactory way of determining the correctness of these percentages except by ascertaining from the accounting records of the railways what their expenditures for such items actually have been. A thorough analysis of the accounting records would probably eliminate all of the item of "contingencies," amounting to \$17,869,000 in the estimate for Minnesota, for any allowance for "contingencies" is always a confession of ignorance as to what the exact expenditure will be or has been. On the other hand, an analysis of accounting records might disclose that the percentages allowed for interest during construction and for engineering are too low, as claimed by many of the railways. We do not say that such would be the result, but so long as the claim is made and so long as such enormous sums of money are at stake, an analysis of the accounting records of every railroad should be made, even though the records may be incomplete for some of the older lines. It does not cost more than \$6 or \$7 per mile of road to make such an investigation and analysis of costs of original construction and betterments. Mr. Morgan informs us that his appraisal cost the state of Minnesota \$8.50 per mile of main track, but of course, this does not include what it cost the railways to make the estimates which Mr. Morgan's forces checked, nor, as we have stated, did Mr. Morgan make an investigation and analysis of the original cost and betterments. The state of Minnesota has secured an exceedingly valuable estimate at a very low cost, but we can not urge too strongly the desirability of a thorough investigation of the accounting records of the railways and the subsequent use of accounting records in keeping cost estimates up to date.

We pass now to a summary of the data collected by Mr. Morgan:

MILEAGE IN MINNESOTA.

(June 30, 1907)

	Miles.
Roadway, or 1st main track.....	7,596
Other main tracks.....	428
Side tracks	2,414
All tracks, total.....	10,438

From this it will be seen that there are 1.38 miles of tracks to each mile of roadway. Hence, the subsequent items of cost per mile of roadway must be divided by 1.38 to get the cost per mile of track.

TABLE XXIII.—COST OF REPRODUCTION AND PRESENT VALUE (7,500
MILES OF ROADWAY.)

	Cost of Reproduction New.	Present Value.
1. Land for right of way, yards and terminals	\$ 73,201,757.70	\$ 73,201,757.70
2. Grading, clearing and grubbing.	56,006,782.11	56,006,782.11
3. Protect work, rip rap, ret. walls.	2,419,292.42	2,419,292.42
4. Tunnels	253,250.00	253,250.00
5. Crossties and switch ties.....	17,491,500.06	9,627,539.85
6. Ballast	9,413,351.34	9,413,351.34
7. Rails	33,010,087.72	25,199,668.20
8. Track fastenings	5,936,740.60	4,543,054.70
9. Switches, frogs, r. r. crossings..	1,389,863.52	962,741.45
10. Track laying and surfacing.....	5,340,689.05	5,340,689.05
11. Bridges, trestles and culverts...	19,567,524.30	14,518,934.30
12. Track and bridge tools.....	201,918.31	151,438.71
13. Fences, cattle guards, signs....	2,768,394.93	1,402,082.54
14. Stockyards and appurtenances..	559,896.31	349,759.71
15. Water stations	1,606,164.62	1,144,535.43
16. Coal stations	717,519.88	507,703.49
17. Station buildings and fixtures...	6,855,358.56	4,097,249.08
18. Miscellaneous buildings	4,344,684.37	3,408,171.52
19. Steam and electric power plants, gas plants	797,484.52	656,069.99
20. General repair shops.....	4,123,119.91	2,959,019.07
21. Shop machinery and tools.....	1,831,671.23	1,484,756.11
22. Engine houses, turntables and cinder pits	2,937,988.58	1,974,436.40
23. Track scales	184,120.00	126,474.45
24. Docks and wharves (incl. coal and ore docks).....	6,065,496.69	5,392,960.86
25. Interlocking plants	403,071.57	293,197.56
26. Signal apparatus	155,766.71	126,217.89
27. Telegraph lines, appurtenances..	1,316,048.16	994,237.19
28. Telephone lines, appurtenances..	94,526.17	70,926.17
29. Adapt. and solid. of road bed...	11,743,007.16	11,743,007.15
Total of items 1 to 29 inclusive...	\$269,636,486.78	\$238,236,206.93
30. Engineering, superintendence, le- gal expense, 4 1/2%.....	12,133,641.89	12,133,641.89
Total of items 1 to 30 inclusive...	\$281,770,128.67	\$250,369,848.82
31. Locomotives	17,090,953.40	12,608,422.67
32. Passenger equipment	6,616,170.78	4,554,442.63
33. Freight car equipment.....	46,911,106.58	34,068,095.26
34. Miscellaneous equipment	1,326,666.16	876,057.17
35. Marine equipment	43,500.00	32,625.00
Total of items 1 to 35 inclusive...	\$358,758,526.59	\$292,503,491.55
36. Freight on crossties, rails, fast- enings, switches and frogs...	3,635,535.03	3,635,535.03
Total of items 1 to 36 inclusive...	\$357,394,060.62	\$296,139,026.58
37. Contingencies, 5% on total of items 1 to 36.....	17,869,703.03	17,869,703.03
38. Stores and supplies.....	5,210,010.98	5,210,010.98
39. Interest during construction.....	31,261,419.93	31,261,419.93
Grand total	\$411,735,194.55	\$360,480,160.51

In Table XXIII it will be noted that the cost of reproduction and the present value of item 36 (freight on track materials) are identical; but since freight is a part of the cost of these materials delivered, and since the materials depreciate, the present value of item 36 should be less than the cost of reproduction. The error in this case arises from the segregation of freight as a separate item, which should not be done.

Item 37 (contingencies) is a percentage of all the previous items. It is not clear why contingencies should be figured on lands, nor on equipment.

By dividing each of the above items of cost of reproduction by 7,596, we have calculated the itemized cost of reproduction per mile of railway, tabulated below. To convert any of these items into cost per mile of track, divide it by 1.33, as above explained:

COST OF REPRODUCTION PER MILE OF ROADWAY. (7,596 MILES.)

1. Land for right of way, yards & terminals..\$	9,637.00
2. Grading, clearing and grubbing.....	7,372.00
3. Protection work, rip rap, retaining walls.	318.00
4. Tunnels	38.00
5. Cross ties and switch ties.....	2,302.00
6. Ballast	1,240.00
7. Rails	4,345.00
8. Track fastenings	782.00
9. Switches, frogs and railroad crossings....	182.00
10. Track laying and surfacing.....	703.00
11. Bridges, trestles and culverts.....	2,576.00
12. Track and bridge tools.....	27.00
13. Fences, cattle guards and signs.....	364.00
14. Stock yards and appurtenances.....	74.00
15. Water stations.....	211
16. Coal stations.....	95
17. Station buildings and fixtures.....	772
18. Miscellaneous buildings.....	572
19. Steam and electric power plants, gas plants..	105
20. General repair shops.....	543
21. Shop machinery and tools ..	241
22. Engine houses, turntables and cinder pits....	373
23. Track scales.....	24
24. Docks and wharves (inc. coal and ore docks)	779
25. Interlocking plants.....	53
26. Signal apparatus.....	20
27. Telegraph lines and appurtenances.....	173
28. Telephone lines and appurtenances.....	13
29. Adaptation and solidification of roadbed....	1,546
30. Engineering, superintendence and legal exp.	1,598
Total of items 1 to 30 inclusive.....	\$37,095
31. Locomotives	2,250
32. Passenger equipment.....	872
33. Freight car equipment.....	6,175
34. Miscellaneous equipment.....	175
35. Marine equipment.....	6
36. Freight on cross ties, rails, switches and frogs, track fastenings.....	478
37. Contingencies	2,362
38. Stores and supplies in Minnesota.....	686
39. Interest during construction.....	4,115
Grand total.....	\$54,304

The details of item 1 (land) are as follows per mile of roadbed:

	Per mile
12.636 acres right of way.....	\$1,317.90
0.620 acres gravel pits, etc.....	33.32
2.973 acres station grounds.....	1,532.28
0.638 acres terminals (St. Paul, Minneapolis and Duluth).....	6,346.34
16.866 acres, total.....	\$9,636.34

These values are not the "normal values" of the land for ordinary purposes, but the "values for railway purposes" as ascertained by applying the multiples above given.

The most significant fact in this land appraisal is the very high percentage that the land for terminals forms. Station grounds also form a large percentage of the total cost for lands. There are many states in which such expensive terminals do not exist, and there are others, like Illinois, Pennsylvania and New York, where the cost of terminals is probably greater per mile of railway.

The details of item 2 (grading, etc.) are as follows per mile of roadway:

22,230 cu. yds. earth at 23.7 cts.....	\$5,380.01
565 cu. yds. loose rock at 51.62 cts.....	291.65
345 cu. yds. solid rock at \$1.077.....	371.57
4.56 acres clearing and grubbing at \$69.35....	318.52
Total	\$7,371.75
Grade revision at Owatonna (\$27,425).....	3.63
Total	\$7,375.38

Mr. Morgan's report contains no further data as to unit costs.

The itemized costs of each of the different railways in Minnesota are given in the report, and it was from a summary of those items that the above given totals and averages were prepared.

We append Table XXIV prepared by the Railway Age Gazette from the data contained in Mr. Morgan's report.

Appraising the Land Value of the Michigan Railways.*—The two letters that follow speak for themselves, and contain matter of interest not only to engineers who are likely to be engaged in railway appraisals but to engineers who may be called upon to appraise real estate and other property for taxation purposes.

H. P. Gillette,

Dear Sir:

In connection with some of your statement's relative to the appraisal of the Michigan State Railroads made some years ago, you discuss admirably the element of real estate values and the methods which you think best to follow.

I gather that you are not quite as familiar with the methods finally employed in this work, because they were so in keeping with your own ideas and even went them one better that it is a pleasure for me to call it to your attention, knowing that you are highly appreciative of original work of this kind, and will be pleased to see that this particular expert's ideas and methods follow your

*Engineering-Contracting, May 5, 1909.

own so very closely and yet are carried out with a little different method as to details; for precision of detail and speed of accomplishment was only possible to a very well defined and carefully considered method entirely and exclusively evolved by Mr. Edward A. Dunbar, a former West Pointer and expert engineer, and well acquainted with real estate matters himself in large enterprises.

For economy of costs and in the completeness of the returns I think it is unexcelled, and has never been approached by any other equally reliable method, except your own; but all of them are much the same and splendid in their discussion of a very difficult and what has heretofore been a vexatious problem to solve.

I hope sometime in the near future to have the great pleasure of meeting you personally, for we highly appreciate your method of thinking about a good many things.

There has been in all this property so much theoretical stuff injected into it that it is very wearisome to practical men, and it is a relief to find some one like yourself who has the courage and the earnestness of purpose and honesty of intention to say so.

Yours truly,

F. T. BARCROFT,

Director of Appraisal.

Detroit, Mich., April 16, 1909.

My Dear Mr. Barcroft.—In compliance with your request I submit herewith a statement of the method by which the land values of the Michigan Railroad Appraisal were deduced.

LAND VALUATION.

The limited time in which full results had to be made known precluded the general adoption of any of the usual methods of land valuation and for that reason the following method was adopted:

Determining the Quantity.—The office inspectors, as they were called, took direct from the maps and other data of the railroad company, and of the registers of deeds offices, all the information necessary to determine the area of the railroad land throughout the state. They subdivided the land, in taking it off by counties and also subdivided it so the right-of-way between stations showed separately from the right-of-way and additional land at stations, or at points where the density of population would enhance the values of land beyond that of farm land.

In the cities the land was all divided into small blocks, so that it might be estimated either by square feet or by the front foot, as might seem most expedient.

Determining the Quality.—As the land throughout the state is not uniform quality the railroads' lands were subdivided into 33 subdivisions—following county lines. And on the basis of its physical characteristics, it was also subdivided into six separate classes, viz.:

- 1st. Farm land.
- 2d. Barren land.
- 3d. Towns under 500 population.
- 4th. Towns under 2,000 population.

5th. Towns under 10,000 population.

6th. Towns over 10,000 population.

To determine the percentage on each railroad in each county of farm and waste land a representative was sent to each of the railway centers of the state. He interviewed roadmasters, assistant roadmasters, locomotive engineers and freight train conductors, as being men who knew every foot of the land over which the railroad passed and from them secured the information which enabled him to report on the percentage of waste land on each railroad by counties.

In the smaller cities and a few of the larger villages the quality of land was determined by our representative going over the land within the city, dividing it up according to the use to which the various sections were put, viz.:

Laborers' residence property.

Mechanics' residence property.

High class residence property.

Manufacturing property.

Second-class store property.

First-class store property.

He also got local experts to value each division, but this really falls under the next head which is:

Determining the Price.—The price of the land in the first five classes, except as next before noted, was determined by sending a letter of inquiry, enclosing a card for reply, to some five hundred representative citizens of the state, taking about six from each county and choosing these citizens from among land dealers, bankers, county surveyors and county treasurers. Each man selected was supposed to be peculiarly adapted as a judge of land values within his county and on the card enclosed was requested to give his estimate of the present value of an average acre of land in his county in each of the five classes.

This method it will be observed assumes that every acre of land of the same class, in a county, is equally valuable and that that value may fairly be taken to be the average price of the land of that class in that county. An average of the prices by classes as given on the cards for each county was therefore taken as the present valuation for the first four classes and partly for the fifth. For part of the fifth and all of the sixth, the price was determined in the usual manner by a board of experts; going over every foot of the property in question and valuing each piece separately; taking into consideration surrounding values, both from selling prices of adjoining land and assessment rolls.

Our method of accumulating this information was by means of a card index file, of which I enclose a sample card. One card was made for each county through which each railroad passed. It is evident therefore that by applying the average prices to the class quantities, determining as hereinbefore described, that each card would represent the total present market value of all the land belonging to the railroad in question in that particular county, and the sum of the values given on all the cards, for any given railroad (that is one card for each county) would equal the actual

present market value of all the land owned by that railroad in the State of Michigan and that the total of all the cards would equal the total present value of all the railroad lands in the State of Michigan.

The question arose in our minds at the outset whether in addressing five hundred strangers, nearly all of whom were busy men, we should get any considerable number of replies to our inquiry and if we did, whether they would not be mere off-hand guesses rather than thoughtful estimates. It is extremely gratifying to be able to say that out of five hundred cards sent out less than fifty have failed to respond. In only one case was the failure to comply with the request based upon the plea of no compensation, and of all the answers received there is scarcely one that does not bear either in itself, or in an accompanying letter, evidence of the most painstaking care. It was noticed in many instances that before making out his card the writer would correspond with from five to twelve different persons in his county, getting their views and then summarizing them on his card.

I do not believe that had we gone over every acre of the land in this state, with a board of inspection and valuation, at enormous expense, we would have arrived at any better result than we did by the inexpensive and expeditious method detailed above.

Yours very truly,

R. C. DUNBAR.

Cost of 1,100 Miles of the C., M. & St. P. R. R. in South Dakota.*
—In the "Spokane Rate Case" before the Interstate Commerce Commission, Mr. A. H. Hogeland, chief engineer of the Great Northern Railway, and Mr. W. L. Darling, chief engineer of the Northern Pacific Railway, presented itemized estimates of the cost of reproducing those two railway systems. Acting for the city of Spokane, Mr. Halbert P. Gillette offered testimony showing that the estimates of Mr. Hogeland and Mr. Darling were too high. Among the facts most strongly in dispute was the allowance to be made for transporting the contractors' men and supplies over the railway to and from the site of the work. Mr. Hogeland testified that $4\frac{1}{4}$ cts. per cu. yd. should be added to the contract price of each yard of earth excavation to cover the added cost to the railway company for transportation. Mr. Darling testified that 3 cts. per cu. yd. would cover this item and Mr. Gillette testified that 1 ct. would be an excessive allowance. In substantiation of his estimate Mr. Gillette presented data of his own and estimates made by other engineers. Among the latter was an estimate of Mr. D. J. Whittemore, made while he was chief engineer of the Chicago, Milwaukee & St. Paul. Mr. Whittemore presented his testimony in 1898 in the "South Dakota Rate Case" under conditions that made it desirable for him to claim all he reasonably could claim on the cost of construction of his road. His estimate covered the original cost of 1,101 miles of main line and 88 miles of sidetracks in South Dakota, which is equivalent to 1.08 miles of main line and

* *Engineering-Contracting*, July 24, 1907.

sidings to each mile of main line. The unit prices used by Mr. Whittemore were based upon those prevailing in 1879 to 1887, the years during which the road was built. He testified that there was practically no rock excavation, which accounts in part for the low unit price in the earthwork.

Believing that Mr. Whittemore's estimate is worthy of being placed permanently on record, we reproduce it herewith. In a subsequent issue we shall give Mr. Hogeland's and Mr. Darling's itemized estimates of the cost of the two great railroad systems of which they are chief engineers:

	Per mile of main line (1,101 miles).
11,300 cu. yds. embankment at 15.10 cts.....	\$ 1,713.10
4.55 cu. yds. riprap at \$1.50.....	6.80
10,000 ft. B. M. timber in bridges and culverts at \$30 per M.....	300.00
425 lin. ft. piles in bridges at 35 cts.....	148.75
Truss bridges at \$4,437 each.....	31.05
1/4 iron pipe culvert in place of wooden one (betterment) at \$50.....	12.50
94.62 tons (gross) rails at \$46.76.....	4,512.40
7,555 lbs. track spikes at 2 1/4 cts.....	188.90
280 pairs rail joint splices at \$1.....	380.00
2,238 cross ties at 30 cts.....	971.40
0.53 switches at \$100.....	53.00
0.01 railroad crossings at \$200.....	2.00
1.08 miles main and side track laid and surfaced at \$450.....	486.00
0.24 miles track ballasted at \$500.....	120.00
Moving track material from store depot to the front.....	140.00
0.92 miles fence at \$1.40.....	128.80
29 panels (0.1 miles) snow fence at \$2.10.....	60.90
260 ft. B. M. crossing plant (1.1 crossings per mile) at \$20.....	5.20
1 cattle guard.....	10.00
Freight on track materials, 1/4 ct. per ton mile...	2,130.00
Freight on contractor's tools and supplies.....	7.50
Freight on contractor's teams.....	6.00
Freight on bridge and culvert material.....	99.00
Transportation of laborers, 6 men transported 500 miles to work at 2 cents per mile.....	60.00
0.23 station sign board, at \$6.00.....	1.40
1.1 highway sign board, at \$5.00.....	5.50
0.04 R. R. crossing sign board, at \$6.00.....	.25
0.04 R. R. crossing stop board, at \$6.00.....	.25
2 whistle posts, at \$1.00.....	2.00
0.45 mile posts, at \$1.00.....	.45
1 rail rest, at \$1.00.....	1.00
Buildings.....	255.00
1 mile right-of-way and station grounds.....	122.00
Telegraph lines.....	64.30
Engineering, superintendence, legal and general office expense.....	300.00
Interest on the above items for 1/2 of two years at 6%.....	777.00
Track tools, 1/4 section at \$128 per section.....	17.25
Station furniture, 1/12 station, at \$78.....	6.50
Betterment to roadbed and bridges, estimated at 5% of above.....	687.00
Stores and supplies.....	300.00
Total (exclusive of equipment).....	\$14,725.70

Mr. Whittemore testified that the \$140 per mile for distributing track material from the store yard was estimated thus:

3 engines and crews at \$25 per day.....	\$50.00
36 cars at 50 cents per day.....	18.00
1 caboose.....	2.00
Total	\$70.00

He stated that one-half mile of track was laid per day, hence it cost two times \$70, or \$140 per mile, to distribute track materials from the material yard.

It will be noted that the cost of transporting men and supplies, as given by Mr. Whittemore, consisted of three items, namely:

Freight on contractor's tools and supplies.....	\$ 7.50
Freight on contractor's teams.....	6.00
Transportation of laborers.....	60.00
Total per mile.....	\$73.50

This is equivalent to 0.66 ct. per cu. yd. of earthwork, if charged entirely to the earthwork.

Prices Used in Estimating Cost of Railways in Texas.*—The Railroad Commission of Texas has appraised the value of roads recently constructed, using a schedule of unit prices which we reproduce herewith.

The railways were paying \$1.50 to \$1.75 per day of 10 hrs. for common laborers in 1906, and found labor very scarce at these wages.

The following unit prices were used in valuing the Trinity & Brazos Valley Ry., from Mexia to Houston, a distance of 165 miles:

	Price.
Right of way, per acre.....	\$ 50.00
Depot grounds, per acre (minimum).....	100.00
Reservoir grounds, per acre.....	25.00
Clearing and grubbing, per acre.....	25.00
Clearing and grubbing, per acre.....	50.00
Earth excavation, per cu. yd.....	0.15
Loose rock excavation, per cu. yd.....	0.40
Solid rock excavation, per cu. yd.....	0.75
Trestle timber, in place, per M.....	40.00
Trestle piling, in place, per lin. ft.....	0.40
Wood drain boxes, per M.....	25.00
Tile drains, 24 in., per lin. ft.....	3.00
Cattle guards, wooden surface.....	40.00
Fences, 4-wire, cedar posts (16 ft. apart) per mile of fence.....	160.00
Road crossings, per M.....	35.00
Ties, L. L. Y. pine (6" x 8" x 8').....	0.70
Rails, 75 lb., per ton.....	35.00
Joints, including bolts, each.....	1.20
Spikes, 34 kegs per mile, per keg.....	5.25
Track laying and surfacing per mile.....	500.00
Car and engine hire during construction, per mi.	250.00
Sidings (60-lb. rail, 2,540 ties per mile), per lin. ft.....	1.15
Switch furniture, per set.....	125.00
Ballast, sand (about 2,500 cu. yds. per mile), per mile.....	750.00
Telegraph line (for 1 wire, construction only, materials furnished by Western Union), per mile	50.00
Passenger depots, small frame, per sq. ft.....	1.00
Platforms for ditto, per sq. ft.....	0.10
Cotton platforms, per sq. ft.....	0.10

*Engineering-Contracting, July 24, 1907.

Engineering and legal expense, 5 per cent of total cost of construction.

Interest during construction, 5 per cent of total cost of construction.

For comparative figures the reader is referred to Lavis' "Railroad Location, Surveys and Estimates," page 193 et. seq.

Itemized Cost of the Northern Pacific Railway System as Estimated by its Chief Engineer.*—In this article we give an estimate prepared by Mr. W. L. Darling, chief engineer of the N. P. Ry., and introduced as part of his testimony in the "Spokane Rate Case" before the Interstate Commerce Commission a few months ago.

While many of the quantities were guessed at by Mr. Darling, and while no quantities at all are given for many items, but simply lump sum estimates, still these data are worthy of being recorded, if only to indicate the relative cost of different items. Engineering, for example, is estimated at 5 per cent of the total, and this percentage is undoubtedly not far from correct, although the actual amount estimated for engineering is unquestionably very liberal.

The reader should bear in mind that this estimate was prepared for the purpose of proving that the Northern Pacific Ry. is not earning an unreasonable amount of money, considering what the physical value of the property is today. The city of Spokane contends not only that it is discriminated against in the matter of transcontinental freight rates, but that the rates are in themselves too high, and yield an unreasonable profit to the railways. The Northern Pacific and Great Northern Ryas. contend that their rates are reasonable and yield only a fair profit; and, in proof, they have submitted estimates of the cost of reproducing their entire systems as they stand today, using what they claim to be current unit prices. Regarding these unit prices, it is only fair to say, that the City of Spokane contends that they are, in nearly every instance, unreasonably high. Mr. Halbert P. Gillette, in behalf of the City of Spokane, testified that much lower unit prices are commonly paid by railways in the northwest. He also criticised the quantities in many instances, claiming that they were mere guesses, and not trustworthy. We shall not go into all the testimony that was offered by both sides in the controversy, further than to put on record an abstract of the testimony of Mr. W. L. Darling, chief engineer of the N. P., and Mr. Hogeland, chief engineer of the G. N.

The mileage of the N. P. is as follows:

	Miles.
Main line, single and second track.....	2,860.67
Branch lines, main and second track.....	2,014.24
Spurs, sidings and yard tracks.....	1,819.88
All tracks, total.....	7,694.79

Of this track only 112 miles is second track.

*Engineering-Contracting, Apr. 16, 1903.

Mr. Darling's estimate of the cost was presented in the following form:

Grading and track.....	\$135,745,971
Grade revisions, 1897 to 1901.....	2,350,800
Turnouts	1,838,750
Permanent bridges.....	9,950,249
Temporary bridges.....	4,284,650
Culverts	3,091,600
Wooden bridges filled.....	4,618,800
Tunnels	3,921,421
Fencing	707,290
Snow fences.....	537,800
Telegraph	1,443,080
Water supply.....	1,971,200
Coaling stations.....	635,900
Wharfs and docks.....	1,725,000
Stock yards.....	152,857
Track scales.....	107,671
Cattle guards.....	57,195
Round houses, turntables, power houses, etc.	1,880,448
Shop buildings.....	3,091,650
Miscellaneous buildings.....	1,578,528
Warehouses	2,886,016
Headquarters building.....	756,800
Furniture	440,000
Passenger stations.....	1,102,304
Combination stations.....	1,408,960
Duluth Union depot.....	343,300
St. Paul Union depot.....	159,300
Interlocking	123,555
Block system.....	44,307
Mile posts and signs.....	129,584
Ash pits.....	79,057
Oil and sand houses	120,960
Shop tools and machinery.....	1,100,000
Kalama ferry and steamer.....	617,400
Lines in Manitoba.....	7,000,000
Joint work, Seattle.....	2,457,000
Total	\$300,155,762
Engineering, 3%.....	9,004,673
Total	\$309,160,435
Contingencies, 10%.....	30,916,043
Total	\$340,076,478
Interest during construction—4% for 2½ yrs., 10%.....	22,677,648
Total	\$362,754,126
Freight equipment.....	30,486,000
Passenger equipment.....	5,898,000
Power	16,430,300
Floating equipment.....	497,000
Grand total.....	\$395,565,426

This does not include lands which were estimated to be worth as follows:

Right of way, not including large terminals	\$31,889,587
Large terminals	75,000,501
N. P. interest in terminal companies	882,655
Coal properties	50,720,120
Total	\$158,492,913
Grand total	461,308,229

This estimate of the value of lands was not made by Mr. Darling. In estimating the cost of grading, Mr. Darling stated that an estimate of quantities was made in 1898, and was as follows:

	Total	Per mile (4,419 mi.).
Clearing, acres	15,089	3.4
Grubbing, stations	21,124	4.8
Earth, cu. yds.	88,334,218	20,000
Loose rock, cu. yds.	7,258,522	1,640
Solid rock, cu. yds.	5,164,479	1,170
Riprap, cu. yds.	1,548,911	350

At that time there were 4,419 miles of main track and branches, plus 850 miles of siding and yard tracks, or a total of 5,269 miles of track. In the year 1907, however, there were 1.4605 times as many miles of track. Hence, it is reasonable to suppose that each of the above quantities is 1.46 times larger now than in 1898. But, in addition to this, Mr. Darling claimed that all embankments had been widened from an original 14 ft. to a present 18 ft., and he estimated that all the above quantities (except the clearing and grubbing) should be multiplied by 1.20 to allow for this increase in bank widening. This would make a total increase of $1.20 \times 1.4605 = 1.7526$. Accordingly, Mr. Darling increased the grading quantities by 75.26% and secured the following quantities, to which he affixed the following unit prices:

22,026 acres clearing at \$30.00	\$ 1,762,880
30,851 stations grubbing at \$16.50	590,042
118,110,918 cu. yds. earth at \$0.28	32,511,055
22,702,627 cu. yds. hardpan at \$0.42	16,255,522
12,721,302 cu. yds. loose rock at \$0.50	6,360,651
9,651,266 cu. yds. solid rock at \$1.10	9,956,392
2,714,621 cu. yds. riprap at \$2.00	5,429,242
Total grading, etc.	\$72,865,791

It will be noted that the 1898 estimate of quantities showed the following classification:

	Per cent.
Earth	88
Loose rock	7
Solid rock	5

But Mr. Darling claimed that fully one-quarter of this earth (or 22% of the total excavation) must have been hardpan, hence his estimate of 22,702,627 cu. yds. of hardpan above given.

Mr. Gillette testified that this 22% allowance for hardpan was fully three times too high. He also testified that it was not at all probable that branch lines built and acquired since 1898 had required as heavy grading as the work done before that time, and

that, in any event, an estimate of increase in yardage would more properly be based upon the increase in the miles of railway "line" rather than in the increase in the miles of "track." The miles of "line" had only increased 33%, as compared with an increase of 46% in the track mileage. Mr. Gillette testified that while it was possible that bank widening had increased the original yardage 30%, he knew that no such increase had occurred in the 1,500 miles of line owned by the Northern Pacific in the state of Washington; but, even conceding that an increase in the widths of embankments had been made throughout the system, certainly no rock cuts had been widened, no hardpan dug, no loose rock excavated, and very little riprap widened. Practically all bank widening had been made by steam shovels working in gravel pits, and that it was not right, therefore to increase the original yardage of solid rock, loose rock and hardpan by 20% when practically no such work had been done.

Mr. Darling's unit prices of reproduction were arrived at as follows:

Clearing:	
Contract price per acre.....	\$75.00
Transportation of men and tools.....	5.00
Total	\$80.00
Grubbing:	
Contract price per station.....	\$15.00
Transportation of men, etc.....	1.50
Total	\$16.50
Earth.....	Per cu. yd.
Contract price, average haul 400 ft.....	\$0.22
Overhaul	0.03
Transportation of men, etc.....	0.03
Total	\$0.28
Hardpan and cement gravel:	
Contract price.....	\$0.35
Overhaul	0.04
Transportation of men, etc.....	0.03
Total	\$0.42
Loose rock:	
Contract price.....	\$0.42
Overhaul	0.04
Transportation of men, etc.....	0.04
Total	\$0.50
Solid rock:	
Contract price.....	\$1.00
Overhaul	0.05
Transportation of men, etc.....	0.05
Total	\$1.10
Riprap:	
Contract price, per cu. yd.....	\$1.75
Extra haul and work.....	0.15
Transportation of men, etc.....	0.10
Total	\$2.00

As to the unit prices for grading, Mr. Gillette testified that all the contract prices were very liberal, and that the allowances for overhaul and transportation were fully three times too high. The unit prices for clearing were too high, because most of the clearing was light clearing, a great deal of it being sage brush. The unit price for riprap was excessive, except for hand placed riprap, and that ordinary riprap could be contracted for at \$1.25 or less.

The cost of the track was estimated as follows by Mr. Darling:

Cost per mile of main track:

117 tons steel at St. Paul at \$31.....	\$3,637.00
7.3 tons angle bars at \$34.....	249.66
0.75 tons bolts and nuts at \$55.....	41.25
3.4 tons spikes at \$42.....	143.48
7.5 tons tie plates at \$44.....	330.00
135.95 tons handled in material yard, at \$1...	135.95
1 extra switch, per mile.....	27.50
Contract price for laying track.....	357.50
Train service and rent of equipment used in hauling to the front.....	375.00
3,000 ties at \$0.55.....	1,650.00
Transportation of ties, rails, etc. (steel hauled 1,000 miles and ties hauled 400 miles at 0.4 ct. per ton mile).....	1,023.80
3,000 cu. yds. gravel ballast at \$0.66.....	1,980.00

Total, per mile.....\$9,941.14

Cost per mile of branch lines:

97 tons steel at St. Paul at \$31.....	\$2,907.00
6.46 tons angle bars at \$34.20.....	220.93
0.75 tons bolts at \$55.....	41.25
3.4 tons spikes at \$42.20.....	143.48
107.61 tons handled in material yard, at \$1...	107.61
1 extra switch.....	27.50
Contract price for track laying.....	375.50
Train service, hauling to the front.....	375.00
2,380 ties at \$0.55.....	1,584.00
Transportation of steel and ties.....	891.24
1,500 cu. yds. ballast at \$0.66.....	990.00

Total, per mile.....\$7,763.51

The ballast was estimated thus:

	Per cu. yd.
Contract price.....	\$0.27
Repairs to steam shovels, etc.....	0.03
Transportation 1½ tons, 60 miles at 0.4 ct. per ton mile.....	0.36
Total	\$0.66

In testifying regarding these quantities and prices, Mr. Gillette states that the Northern Pacific was not fully tie plated even on its main line; that the contract price for track laying was excessive; that the allowance for train service was nearly three times what such service actually costs; that the price of ties was excessive; that the estimated price of the gravel ballast was at least 50% too high, and that the quantity of ballast per mile was fully 50% in excess of the actual quantity.

Mr. Darling estimated the cost of each turnout as follows:

Set of switch ties.....	\$ 54.00
Switch stand.....	13.30
Connecting rod.....	1.65
Frog.....	22.00
Roll switch.....	21.00
Rail braces.....	1.60
Switch lamp.....	5.00
Guard rails.....	2.80
Freight charges.....	14.40
Total	\$162.75

For the weight of rail used, and considering the character of the average turnout, this estimate is high.

Mr. Darling estimated the cost of the tunnels on the system as follows:

- 3,390 lin. ft. tunnels under 700 ft. in length.
- 1,090 lin. ft. tunnels of 700 to 1,200 ft. each.
- 7,548 lin. ft. tunnels of 1,200 to 4,000 ft. each.
- 9,833 lin. ft. tunnels, very long tunnel.

The above are single track tunnels lined with concrete. Beside these there were 4,919 lin. ft. of single track tunnels lined with wood, and 1,656 lin. ft. of double track tunnel lined with concrete.

The cost of single tunnels per lineal foot was estimated as follows:

Concrete lining:	Per cu. yd.
Contract price.....	\$ 9.00
1½ bbls. cement.....	2.50
Freight	1.00
Total	\$12.50

With concrete averaging 2 ft. in thickness, there would be 4.1 cu. yds. per lin. ft.; hence the cost of lining would be $4.1 \times \$12.50 = \51.25 per lin. ft. of tunnel.

The cost of short tunnels (up to 800 ft.) was estimated as follows per lin. ft.:

	Per lin. ft.
Contract price.....	\$ 50.00
Add 10% for extra excavation to make room for lining.....	5.00
Concrete lining.....	51.25
False work.....	13.00
Total	\$119.25

For similar tunnels lined with wood instead of concrete, the estimate was \$24.75 per lin. ft. for wood lining plus \$55 for excavation, making a total of practically \$80.

For longer tunnels the item of lining remained the same, but the item of excavation was estimated as follows:

Length of tunnel:	Price per ft.
Up to 700 ft.....	\$50 plus 10% = \$55.00
700 to 1,200 ft.....	55 plus 10% = 60.50
1,200 to 4,000 ft.....	75 plus 10% = 82.50
4,000 to 10,000 ft.....	90 plus 10% = 99.00

The 10% is added to cover the cost of the extra excavation to make room for the lining, and to these prices must be added the cost of the lining itself.

Mr. Gillette testified that the unit prices for tunnel excavation were very liberal, and that the allowance for lining was excessive. The allowance for "falsework," he said, seemed to be in error by a misplaced decimal point, and would be nearer correct if it were \$1.30, since it could refer to nothing but the materials used in the forma, centers, etc.

Mr. Darling's estimate of the cost of short double track tunnels was as follows per lin. ft.:

Contract price \$50 plus 10%.....	\$ 55.00
11 5 cu. yds. extra excavation at \$3.....	34.50
6.2 cu. yds. concrete at \$12.50.....	65.00
Falsework	13.00
Total	\$167.50

Mr. Darling's estimate of bridges was not given in much detail, but was as follows:

Howe truss bridges.....	\$ 694,580
Steel and combination bridges.....	9,950,248
359,000 lin. ft. trestles at \$10..	3,590,000
Trestles filled with earth.....	3,012,415
Total bridging.....	\$17,247,243

Other items were estimated as follows:

4,576 miles fencing at \$154.56.....	\$ 707,290
Water supply.....	1,971,200
1,750,000 sq. ft. wharfs and docks at \$0.70..	1,225,000
Coaling stations.....	625,926
3,412,000 sq. ft. stock yards at 4.48 cts....	152,857
74 track scales at \$1,456.....	107,671
3,464 cattle guards at \$16.80.....	57,195
Roundhouses, turntables, power houses, etc.	1,680,448
Shop buildings.....	2,091,660
Warehouses	2,886,016
Headquarters building.....	756,600
Passenger stations.....	1,102,304
Combination stations.....	1,408,960
Interlocking plant.....	123,555
Mile posts and signs (5,785 miles at \$22.40)	129,584
Ash pits.....	79,067
Oil and sand houses at \$1.68 per sq. ft....	120,960
Block system	44,307
Miscellaneous buildings and piping.....	1,576,528
220 miles snow fences at \$1,680.....	537,600

The above costs include freight on the materials, and, in nearly every instance, this freight was estimated at 12% of the unit price assumed; thus, oil and sand houses were estimated at \$1.50 per sq. ft. plus 12% for freight, making a total of \$1.68 per sq. ft.

The following unit prices for building were used by Mr. Darling, and do not include freight:

Frame roundhouses, per stall.....	\$1,300.00
Brick roundhouses, per stall.....	2,100.00
Turntables, each.....	5,000.00
Brick shops (1-story) per sq. ft.....	1.50
Brick shops (2-story) per sq. ft.....	2.50
Frame shops (1-story) per sq. ft.....	1.00
Frame warehouses, per sq. ft.....	1.20
Brick warehouses, per sq. ft.....	1.60
Frame passenger stations, per sq. ft.....	1.50
Brick passenger stations, per sq. ft.....	3.50
Frame combination stations (1-story) per sq. ft.....	1.50
Frame combination stations (2-story) per sq. ft.....	2.50
Oil and sand houses, per sq. ft.....	1.50

Mr. Darling failed to give the number of square feet of each of these different kinds of buildings.

For purposes of comparison, Mr. Gillette rearranged the foregoing figures of cost, following the classification used by the Interstate Commerce Commission, and divided each item by 5,875 miles, which is the mileage of main line and branches on the Northern Pacific system. The following table gives the results of this calculation, showing the cost per mile of main line and branches, and the percentages:

	Per mile.	Per cent.
1. Engineering	\$ 1,027	2.04
2. Grading	12,814	25.44
3. Tunnels	670	1.23
4. Bridges, trestles and culverts.....	2,722	7.28
5. Ties	2,719	5.40
6. Rails	4,850	9.83
7. Frogs and switches.....	342	0.63
8. Track fastenings.....	705	1.40
9. Track laying.....	1,122	2.24
10. Ballasting	1,776	3.53
11. Fencing	116	0.23
12. Crossings, cattle guards and signs ..	30	0.06
13. Interlocking and signal.....	25	0.05
14. Telegraph lines.....	247	0.49
15. Station buildings.....	1,122	2.24
16. Shops and roundhouses.....	675	1.34
17. Machinery and tools.....	126	0.27
18. Water stations.....	227	0.67
19. Fuel stations.....	111	0.22
20. Warehouses	493	0.97
21. Docks and wharves.....	292	0.50
22. Miscellaneous structures.....	403	0.80
23. Interest	3,860	7.66
24. Marine equipment	106	0.21
25. Contingencies	3,509	6.97
26. Freight equipment.....	5,202	10.22
27. Passenger equipment.....	1,002	1.97
28. Locomotives	2,804	5.57
29. Floating equipment.....	86	1.17
Total	\$ 50,370	100.00
Total	295,916,693	
Right of way and station grounds.....	107,772,743	
Grand total.....	\$403,689,436	

The above does not include lines in Manitoba, estimated to cost \$7,000,000 to reproduce, nor the coal properties valued at \$50,720,120.

It will be noted that the \$50,370 per mile multiplied by the 5,874.91 miles does not give exactly the total of \$295,916,693. This is due to the fact that a slide rule was used in computing the cost of each item per mile, and absolute precision was not obtained. However, the error is only \$4 per mile.

The reader should also note that the above costs per mile are not costs per mile of track, but per mile of all main and branch lines. Since there are 7,694.79 miles of all track, and only 5,874.91 miles of main and branches, there are 0.77 mile of main and branches for each 1.00 mile of "all tracks." Hence if we multiply any of the above 29 items by 0.77 we shall have the cost per mile of all tracks. Thus, item 9, Track Laying, is \$1,128, which is the cost per mile of main line and branches, sidings and yards being lumped in. But the estimated cost of laying each mile of every kind of track is $0.77 \times \$1,128 = \868 .

In our issue of June 22, 1907, are given estimates of the cost of all the railways in Wisconsin and Michigan. In a subsequent issue we shall give the estimated cost of the Great Northern Ry. system. A comparison of these various estimates should prove instructive to every engineer interested in railway construction.

Itemized Cost of the Great Northern Railway System as Estimated by its Chief Engineer.*—In our issue of April 15 we gave an estimate of the cost of the Northern Pacific Railway similar to the one that will be given here. Both these estimates were presented as testimony before the Interstate Commerce Commission in their hearing of the "Spokane Rate Case." Since the object of the hearing was to ascertain the reasonableness of railway rates on the N. P. and on the G. N. railways, the railways naturally claimed a high physical value for their property. As stated in our April 15 issue, Mr. Halbert P. Gillette, testifying in behalf of the city of Spokane, claimed that the estimates presented by the railways were much too high, frequently being high not only as to unit prices but as to quantities.

Mr. A. H. Hogeland, Chief Engineer of the Great Northern Railway, presented the following as his estimate of the cost of reproducing the railway new at present prices.

The mileage of the Great Northern under operation April 1, 1907, was:

	Miles.
Main track.....	6,523.09
Second, 3d, 4th, 5th and 6th track.....	112.25
Side track.....	1,480.24
Grand total of all tracks.....	8,115.58

**Engineering-Contracting*, May 6, 1908.

Mr. Hogeland's estimate of the cost was presented in the following summarized form:

1. Engineering	\$ 6,870,187
2. Right of way and station grounds....	87,067,532
3. Grading	93,098,889
4. Tunnels	7,447,620
5. Bridges, trestles and culverts.....	17,953,028
6. Ties	18,690,731
7. Rails	31,054,392
8. Track fastenings.....	7,375,495
9. Frogs and switches.....	904,450
10. Ballast	10,509,000
11. Track laying and surfacing.....	6,998,409
12. Fencing right of way.....	760,815
13. Crossings, cattle guards and signs....	1,922,160
14. Interlocking or signal apparatus.....	286,190
15. Telegraph lines.....	2,198,293
16. Station buildings and fixtures.....	3,276,300
17. Shops, roundhouses and turntables....	3,667,900
18. Shop machinery and tools.....	1,779,692
19. Water stations.....	1,983,326
20. Fuel stations.....	675,700
21. Grain elevators.....	2,708,100
22. Storage warehouses.....	276,500
23. Docks and wharves.....	1,222,900
24. Gas making plants.....	15,000
25. Miscellaneous structures.....	3,184,850
26. Track and bridge tools.....	142,877
27. Stores and supplies on hand Feb. 23, 1907	5,395,463
28. Contingencies	15,291,262
29. Equipment:	
Locomotives	\$10,756,324
Passenger cars.....	4,915,764
Frt. cars and other equip. 25,349,096	
	<u>40,921,184</u>
Total	\$273,688,224
30. General and legal expenses (1%).....	2,736,882
	<u>Total</u>
	\$277,425,106
31. Interest during constr. (10%).....	37,742,510
	<u>Grand total.....</u>
	\$415,167,616

Engineering was estimated at 3% of all items requiring engineering supervision, being all items except items 2, 26, 27, 29, 30 and 31.

Right of way and station grounds were estimated by the Right of Way Department.

The grading was estimated as follows:

27,018 acres clearing at \$82.50.....	\$ 2,228,985
340,000 sq. rods grubbing at \$1.65.....	561,000
165,438,650 cubic yards earth at \$0.31.....	51,285,982
33,973,350 cubic yards hardpan at \$0.45.....	15,288,908
8,441,860 cubic yards loose rock at \$0.55.....	4,643,023
12,771,060 cubic yards solid rock at \$1.10.....	14,048,166
1,765,675 cubic yards riprap at \$2.00.....	3,531,350
92,500 cubic yards retaining wall at \$9.00.....	832,500
194,250 cubic yards slope wall at \$3.50.....	679,875
	<u>Total grading.....</u>
	\$93,098,889

Mr. Hogeland testified that the quantities of grading were arrived at as follows: "For 82% of the mileage of the system the actual quantities moved in construction were obtained from Engineering Department records. For the balance of the system the quantities could not be obtained in that way, because no records were available, and they were estimated from profiles and by comparison with adjacent portions of the system where the quantities were known. To these quantities were added the quantities moved since construction, in widening banks, reducing grades, taking out sags, filling bridges and widening and deepening cuts. The result being the actual quantities as nearly as possible to arrive at same, required to make the roadbed as it exists to-day."

It will be noted that Mr. Hogeland's estimate gives an average of 33,250 cu. yds. of excavation per mile of main track, distributed thus:

	Per cent.
Earth	75.0
Hardpan	15.4
Loose rock.....	3.8
Solid rock.....	5.8
Total	100.0

Mr. Hogeland testified that the part of the G. N. east of Havre (4,553 miles of main line) averaged 27,760 cu. yds. per mile, whereas the line west of Havre (2,082 miles of main line) averaged 45,250.

Mr. Hogeland gave the percentages as follows:

	East of Havre. Per cent.	West of Havre. Per cent.
Earth	88.4	57.0
Hardpan	10.2	32.4
Loose rock.....	1.1	7.4
Solid rock.....	0.3	13.2
Total	100.0	100.0

Mr. Gillette testified that Mr. Hogeland's estimate of yardage per mile was much too high, and cited actual records of the G. N. in the state of Washington where much of the heaviest grading on the G. N. is found. But, as we shall publish in detail Mr. Gillette's quantities and estimates of cost of each of the railway systems in the state of Washington, the reader may make comparisons for himself.

Mr. Hogeland arrived at his unit prices as follows:

	Per acre.
Clearing:	
Contract price.....	\$75.00
Transporting men, tools and supplies.....	7.50
Total	\$82.50

Grubbing:	Per sq. rod.
Contract price.....	\$1.50
Transporting men, etc.....	0.15
Total	\$1.65
Earth:	Per cu. yd.
Contract price up to 1,000 ft. haul.....	\$0.21
Overhaul	0.035
Transporting men, etc.....	0.045
Total	\$0.21
Hardpan:	Per cu. yd.
Contract price up to 1,000 ft.....	\$0.35
Overhaul	0.045
Transporting men, etc.....	0.055
Total	\$0.45
Loose rock:	Per cu. yd.
Contract price up to 1,000 ft.....	\$0.45
Overhaul	0.045
Transporting men, etc.....	0.055
Total	\$0.55
Solid rock:	Per cu. yd.
Contract price up to 1,000 ft.....	\$1.00
Overhaul	0.045
Transporting men, etc.....	0.055
Total	\$1.10
Riprap:	Per cu. yd.
Contract price.....	\$1.50
Overhaul or train service.....	0.25
Transporting, etc.....	0.15
Total	\$2.00
Retaining wall:	Per cu. yd.
Contract price (concrete or rubble).....	\$7.50
Train service.....	0.80
Transporting men, etc.....	0.70
Total	\$9.00
Slope wall:	Per cu. yd.
Contract price.....	\$2.50
Train service.....	0.75
Transporting men, etc.....	0.25
Total	\$3.50

It is interesting to note in this connection that the actual yardage of excavation on about 700 miles of the G. N. in the state of Washington was 26,000 cu. yds. per mile for the original construction in the early '90's, and that the item of "overhaul" actually averaged less than $\frac{1}{2}$ ct. per cu. yd. for every yard of material excavated, as compared with the $4\frac{1}{2}$ cts. estimated by Mr. Hogeland. The free haul limit was 1,000 ft. Much the same criticism also applies to Mr. Hogeland's estimate of the cost of transporting men and supplies to and from the site of the work.

RAILWAYS.

1867

Mr. Hogeland's estimate of tunnels was as follows:

5,222 lin. ft. unlined single track tunnel at \$70.....	\$ 366,240
17,346 lin. ft. timber lined single track tunnel at \$120....	2,081,520
6,129 lin. ft. concrete lined single track tunnel (Boulder) at \$175.....	1,074,325
12,813 lin. ft. concrete lined single track tunnel (Cascade) at \$195.....	2,493,535
5,141 lin. ft. concrete lined double track tunnel at Seattle, \$1,848,000, two-thirds to G. N.....	1,232,000
Total	\$7,447,620

The unit prices were arrived at as follows:

Unlined tunnel:	Per lin. ft.
Contract price for standard unlined section.....	\$55.00
Extra excavation.....	8.00
Transporting men, tools, supplies, etc.....	7.00
Total	\$70.00

Timber lined tunnel:	Per lin. ft.
Contract price for standard unlined section.....	\$ 55.00
Enlargement for timber lining.....	30.00
Timber and iron in place.....	25.00
Transporting men, etc.....	10.00
Total	\$120.00

Concrete lined tunnels: **Per lin. ft.**

(BOULDER TUNNEL.)

Excavation	\$ 90.00
Temporary timber lining.....	20.00
Permanent masonry lining.....	45.00
Transporting men, etc.....	20.00
Total	\$175.00

(CASCADE TUNNEL.)

	Per lin. ft.
Excavation	\$ 95.00
Temporary timber lining.....	25.00
Permanent concrete lining.....	50.00
Transporting men, etc.....	25.00
Total	\$195.00

Bridges, trestles and culverts:

1 stone arch (Minneapolis), 1,770 lin. ft....	\$ 867,000
260 steel bridges with masonry piers, 63,557 lin. ft.....	6,941,645
3,934 timber trestles, 429,851 lin. ft.....	5,216,480
189 Howe truss spans, 19,996 lin. ft.....	905,478
4,940 permanent culverts.....	3,021,685
4,021 timber culverts.....	1,000,740
Total	\$17,953,028

Mr. Hogeland did not give the number of pounds of steel, yardage of masonry, etc. He stated, however, that he used the following unit prices, to which he subsequently added $\frac{1}{2}$ ct. per ton per mile for transporting the materials, so that these unit prices do not include the cost of transporting the materials:

Steel in bridges:	Per ton.
Contract price ready to erect, f. o. b. St. Paul...	\$65.00
Mill and shop inspection.....	.75
Erection	12.00
Painting	2.25
Total	\$80.00

This is equivalent to 4 cts. per lb. erected, exclusive of the cost of transportation from St. Paul.

Masonry:	Per cu. yd.
First class.....	\$12.00
Second class.....	8.00
Concrete	6.00

Excavation, coffer dams, pumping, etc., variable.

Timber trestles:

Timber in place, per M.....	\$31.50
Piling in place, per ft.....	0.35
Wrought iron, per lb.....	0.05

Freight to be added.

Howe truss spans:	Per lin. ft.
44 ft.....	\$18.50
60 ft.....	27.00
75 ft.....	34.00
87 1/2 ft.....	35.50
100 ft.....	37.50
125 ft.....	42.00
150 ft.....	45.00

Freight to be added.

Howe truss timber, per M.....	\$25.00
Rods, plates, etc.....	0.03
Bolts	0.025

Freight to be added.

Vitrified pipe culverts:	Per lin. ft.
12-in. pipe.....	\$0.25
18-in. pipe.....	0.50
24-in. pipe.....	1.15
27-in. pipe.....	1.52

Freight to be added.

Cast iron pipe culverts, \$30 per net ton, plus freight.

Mr. Hogeland estimated 2,850 ties per mile of main track and 2,750 per mile of side track, at the following cost:

Delivered on right of way.....	\$0.48
Train service and loading and handling.....	0.09
Burnettizing 1/4 of all ties at 16 cts.....	0.04
Transporting 500 mi. at 1/2 ct. ton mile.....	0.21
Total	\$0.82

He estimated 2,880 sets of switch ties as follows per set:

F. o. b. mill, per M.....	\$60.00
Transporting 500 miles, per M.....	15.00
Total	\$75.00

The rails for the main track averaged 68.1 lbs. per yd. and for the side track 60 lbs. Five rails per mile were added for "repair rails." The cost of rails was estimated to be:

	Per gross ton.
F. o. b. St. Paul, including handling.....	\$32.00
Transp. 800 miles at $\frac{1}{2}$ ct. ton mile.....	4.00
Total	\$36.00

Angle bars were estimated at 17,600 lbs. per mile of side track at a cost of:

	Per net ton.
F. o. b. St. Paul.....	\$40.00
Transporting 800 miles.....	4.00
Total	\$44.00

Bolts and nuts were estimated at 1,800 lbs. per mile of main track and 1,500 lbs. per mile of side track, at a cost of:

	Per net ton.
F. o. b. St. Paul.....	\$54.00
Transporting 800 miles.....	4.00
Total	\$58.00

Spikes were estimated at 6,500 lbs. per mile of track, at a cost of:

	Per net ton.
F. o. b. St. Paul.....	\$42.00
Transporting 800 miles.....	4.00
Total	\$46.00

Tie plates were estimated at 29,000 lbs. per mile of track where fully tie plated (or 5 lbs. per tie plate), and it was assumed that 2,451 miles were fully tie plated and 1,950 miles half tie plated, as a cost of:

	Per net ton.
F. o. b. St. Paul.....	\$45.00
Transporting 800 miles.....	4.00
Total	\$49.00

It was assumed that 750 miles of track were provided with rail braces at 2,000 braces per mile, at a cost of 10 cts. per brace.

Summary of track fastenings:

Angle bars.....	\$3,090,736
Bolts and nuts.....	431,288
Spikes	1,304,284
Tie plates.....	2,399,187
Rail braces.....	150,000
Total	\$7,375,495

Mr. Gillette testified that these items were substantially correct except as to the number of tie plates, which was very much over-estimated.

Frogs and switches:	
Complete turnout, f. o. b. St. Paul (2,750 lbs.)....	\$85.00
Transp. 800 mi. at $\frac{1}{2}$ ct. ton mile.....	7.50
<hr/>	
Total	\$92.50
2,880 turnouts (except ties) at \$92.50.....	\$268,400
302 crossing frogs at \$275.....	83,050
<hr/>	
Total	\$351,450

The "complete turnout" includes switch stand and bolts, lamp, switch points, connecting and tie rods, plates, rail braces, clips, frog and guard rail, but does not include cross ties.

Mr. Hogeland estimated that 3,750 miles of the main track averaged 3,000 cu. yds. of gravel ballast per mile, and that 1,900 miles averaged 2,250 cu. yds. per mile. Of the 1,480 miles of side track, he estimated that 950 miles were ballasted with 1,500 cu. yds. per mile. This made a grand total of 16,950,000 cu. yds. of ballast on the system, the cost of which was estimated as follows:

	Per cu. yd.
Loading, unloading, putting under track and dressing track.....	\$0.27
Maintenance and repairs of steam shovels.....	0.05
Train service, hauling, repairs and rental of equipment, transp. of men, tools and supplies.....	0.30
<hr/>	
Total	\$0.62

Mr. Gillette testified that this estimate of unit cost was fully 50 per cent more than the actual cost as shown by the records of the G. N. and that gravel ballast could be placed for less than 40 cts. per cu. yd. under existing conditions.

Mr. Hogeland estimated the cost of track laying and surfacing as follows:

	Per mile.
Curving rails, laying and surfacing.....	\$350.00
Labor of tie plating (average).....	45.00
Train service and rental of equipment and hauling to front.....	\$90.00
Transporting men, supplies, etc.....	50.00
<hr/>	
Total	\$535.00
8,115.58 miles at \$535.....	\$4,341,856
8,880 switches placed at \$25.....	222,000
<hr/>	
Total	\$4,563,856

Mr. Gillette testified that the item of train service was about three times higher than the actual cost, and that the transportation of men, etc., was even more excessive.

Mr. Hogeland estimated 4,611 miles of right of way fences at the following cost per mile:

	Per mile.
Standard fence.....	\$150.00
Train service distributing materials.....	10.00
Transporting men, etc.....	5.00
Total	\$165.00

He estimated the cost of crossings, cattle guards and signs as follows:

6,635.34 miles of \$75 for cattle guards, signs, etc. \$	497,650
58 steel highway bridges (overhead).....	1,344,000
Timber bridges (overhead).....	80,510
Total	\$1,922,160

Interlocking and signal apparatus:

Interlocking	\$327,750
Block signaling.....	58,440
Total	\$386,190

Telegraph lines:

Labor	\$ 650,614.48
Material	1,396,307.46
Train service.....	16,638.00
Transp. men, tools, material, etc.....	219,598.22
Quadruplex instruments, batteries, furniture, etc., in 8 main offices.....	16,225.00
Total	\$2,198,283.16

This is equivalent to the following cost per mile of telegraph line:

	Per mile.
Labor	\$ 98.00
Material	200.00
Train service.....	2.50
Transporting men, etc.....	32.00
Quadruplex instruments, etc.....	2.50
Total	\$336.00

Mr. Gillette testified that this was an excessive estimate, and that, so far as the state of Washington was concerned, the G. N. did not own a large part of the telegraph lines and that, in fact, it was the common practice for railways to share the ownership of the lines with telegraph companies, as shown by the accounting records of the railways:

Passenger depots:

Seattle (one-half interest).....	\$ 295,000
Spokane	137,500
Grand Forks.....	37,500
Fargo	41,800
Sioux City.....	180,000
Minneapolis union depot.....	342,500
29 other passenger depots of brick or stone..	419,800
705 frame passenger and freight depots....	1,226,700
14 freight depots of brick or stone.....	422,900
Frame freight houses.....	172,800
Total	\$3,276,200

The St. Paul union depot (of which the G. N. owns one-ninth interest) and the Superior depot (of which the G. N. owns one-third interest) are not included above, but are included under "right of way and station grounds." Mr. Hogeland did not give any dimensions of buildings, so that it is impracticable to check his estimates.

Shops, roundhouses and turntables:

Shop, St. Paul.....	\$ 854,400
Shop, St. Cloud.....	75,400
Shop, Superior.....	91,000
Shop, Barnesville.....	17,500
Shop, Sioux City.....	12,500
Shop, Devils Lake.....	60,000
Shop, Havre.....	91,000
Shop, Great Falls.....	42,000
Shop, Spokane.....	124,800
Shop, Everett.....	70,200
Roundhouses, frame, 88 stalls, at \$1,400....	123,200
Roundhouses, masonry, 554 stalls, at \$2,100	1,168,400
Boiler houses, power houses and small shops	216,000
Turntables, frame, 10, at \$1,800.....	18,000
Turntables, steel, 57, at \$6,500.....	370,500
Cinder pits.....	140,000
Store houses, oil and sand houses and scrap bins	198,000
Total	\$3,667,900

Water stations:

426 water stations (at \$4,722).....	\$1,983,326
--------------------------------------	-------------

This includes tanks, pump houses, pumps, engines, wells, reservoirs and all appurtenances of water stations. It will be noted that this supplies one station every 16 miles of road.

Fuel stations:

52 standard coaling stations at \$9,500.....	\$ 544,500
52 platforms coaling stations, portion with cranes and buckets, \$600.....	31,200
Total	\$ 575,700

Grain elevators:

Minneapolis	\$ 240,000
Superior, A and X.....	823,100
Superior S (steel).....	1,536,400
Seattle, Smith's Cove.....	108,600
Total	\$2,708,100

Storage warehouses:

Superior, flour shed.....	\$ 142,800
Five wool houses.....	19,800
Seattle, warehouse, Smith's Cove.....	113,900
Total	\$ 276,500

Docks and wharves (including dredging):

Superior No. 1.....	\$ 175,000
Superior No. 2.....	80,800
Superior Nos. 5 and 6 and machinery.....	449,500
Seattle, Smith's Cove dock.....	517,600
Total	\$1,222,900

Miscellaneous structures:

General office building, St. Paul.....	\$ 590,000
Division office buildings.....	18,000
Boarding houses.....	87,500
Section houses, bunk houses, hand car houses	852,600
Ice houses.....	107,500
Stock yards.....	157,600
Track scales.....	92,250
Snow sheds.....	295,000
Snow fences.....	450,000
Loading platforms.....	71,000
Quarry and crusher plants.....	45,000
Tie treating plant.....	85,000
Commissary buildings.....	15,000
Miscellaneous buildings.....	227,500

Total\$3,194,850

Mr. Hogeland allowed 10 per cent of items 3, 4, 5, 10, 11, 16, 17, 19, 20, 21, 22, 23 and 25 for "contingencies," to cover the increased cost of the work due to unforeseen causes, such as fires, floods, tornadoes, accidents, etc. Mr. Gillette testified that, while an allowance for "contingencies" is certainly permissible in estimating the cost of projected work, it is not permissible in estimating the cost of completed work, particularly where the actual costs are on record for nearly all the work, as is the case of the G. N.

In estimating the interest charges during construction, Mr. Hogeland assumed that the system, including equipment, would be unproductive for a period of two years. He assumed that it would take eight years to reproduce the system, 1,000 miles of track (main and side) being built per year, and that it would be two years after the beginning of the work before the first 1,000 miles would produce sufficient revenue to pay interest on the investment, and so on with the rest. Hence, two years at 5% is 10% of the total cost to be charged for interest.

It will be interesting to compare this estimate with the actual interest charges as taken from the ledgers of the different railway companies operating in the state of Washington. These data will be published in this journal in the near future, along with the other items of actual cost as ascertained by Mr. Gillette for the Railroad Commission of Washington.

For purposes of comparison with the estimated cost of the N. P. (published in our April 15 issue) we append the estimated cost of the G. N., by items per mile of main and second track, as determined by dividing Mr. Hogeland's items by 6,635.34.

The mileage of the Great Northern under operation April 1, 1907, was:

6,635.34 miles main and second tracks.
1,480.24 miles side tracks.
<hr/> 8,115.58 miles total tracks.

There are only 112.25 miles of second track included in the above, and it will be seen that there is 0.22 mile of side track per mile of main and second track.

Cost of reproduction per mile
of main and
second track.
(6,635.24 miles.)

1. Engineering	\$ 1,035
2. Right of way and station grounds.....	13,160
3. Grading	14,020
4. Tunnels	1,079
5. Bridges, trestles and culverts.....	3,705
6. Ties	2,820

Deduct right of way and station grounds..... 13,160

Cost, exclu. of right of way and sta. grounds..\$49,410
Deduct equipment..... 6,170

Cost, exclusive of lands and equipment.....\$43,240

Contract Prices for Railway Work in the State of Washington.*—
In building the Chicago, Milwaukee & St. Paul line through the
state of Washington, the contract prices for work let in 1906 were
as follows:

	Average price per cu. yd.
Earth excavation, haul 300 ft. or less, \$0.17 to \$0.22.....	\$0.19
Earth excavation, haul 300 to 1,000 ft., \$0.21 to \$0.27.....	0.23
Hard pan, haul 1,000 ft. or less, \$0.30 to \$0.43.....	0.37
Cement gravel, haul 1,000 ft. or less, \$0.36 to \$0.40.....	0.38
Loose rock, haul 1,000 ft. or less, \$0.33 to \$0.45.....	0.42
Solid rock, haul 1,000 ft. or less, \$0.60 to \$1.00.....	0.90
Riprap, loose, haul 1,000 ft. or less.....	0.75
Riprap, hand placed, haul 1,000 ft. or less.....	1.35
Overhaul, for each 100 ft. beyond 1,000 ft.....	0.61

*Engineering-Contracting, Dec. 15, 1909.

Other prices were as follows for different units:

Clearing, per acre, \$40.00 to \$200.00.....	\$120.00
Grubbing, per station, \$10.00 to \$20.00.....	15.00
Ties made on right-of-way, each.....	0.12
Tunneling (800 ft. long or less), per lin. ft.....	45.00
Tunnel enlargement, per cu. yd.....	2.00
Tunnel timber in place, per M.....	28.00
Log culverts, per lin. ft. of logs.....	0.14

The contract prices on the Portland and Seattle Ry., built in Washington at the same time as the C. M. & St. P., were as follows:

	Per cu. yd.
Earth excavation, haul 300 ft. or less.....	\$0.17
Earth excavation, haul 300 to 1,000 ft.....	0.21
Hardpan, haul 1,000 ft. or less.....	0.35
Loose rock, haul 1,000 ft. or less.....	0.40
Shell rock, haul 1,000 ft. or less.....	0.30
Solid rock, haul 1,000 ft. or less.....	0.30
Riprap, loose, haul 1,000 ft. or less.....	0.30
Riprap, hand placed, haul 1,000 ft. or less.....	1.35
Overhaul for each 100 ft. beyond 1,000 ft.....	0.01

Other prices were as follows on different units:

Clearing, per acre.....	\$ 25.00
Grubbing, per sq. rod.....	1.50
Wrought iron, spikes, etc., in structures, per lb.....	0.05
Cast iron in structures, per lb.....	0.05
Square timber in culverts, per M.....	20.00
Flatted timber in culverts, per lin. ft.....	0.12
Tunnel in rock (16 x 24 ft.), per lin. ft.....	45.00
Tunnel, extra excavation, per cu. yd.....	2.00
Tunnel timber lining, including iron, per M.....	20.00
Piling, per lin. ft., cut off.....	0.10
Piling per lin. ft., driven.....	0.20
44-ft. Howe truss bridge, per lin. ft.....	0.25
60-ft. Howe truss bridge, per lin. ft.....	12.50
75 to 88-ft. Howe truss bridge, per lin. ft.....	19.00
100-ft. Howe truss bridge, per lin. ft.....	20.00
120 to 125-ft. Howe truss bridge, per lin. ft.....	21.00
150-ft. Howe truss bridge, per lin. ft.....	22.00
Concrete (cement furnished by the company), per cu. yd.....	6.00
Concrete in tunnels (cement furnished by the company), per cu. yd.....	7.00
Track laying, including loading all material, per mile.....	200.00
Switches placed, each.....	25.00
Placing tie plates, per mile, fully tie plated.....	75.00
Ballast (gravel), including track surfacing, per cu. yd.....	0.27

The price for ballast does not include hauling it, which was done by the railway company. The prices for Howe truss bridges include all materials except the iron, and all framing and erecting.

Record of Rapid Construction on the C. P. Ry.—In the Jour. Assoc., 1884, p. 150, Mr. E. T. Abbott gives a brief account of the rapid construction of 500 miles of single track road across the prairies from Brandon (132 miles west of Winnipeg). Ground was broken May 28, 1882, and continued to Dec. 31. In 182 working days, including stormy ones, with a force of about 5,000 men and 1,700 teams, the contractors did the following:

6,104,000 cu. yds. earth excavation (or 14,000 cu. yds. per mile), 2,294 M. timber in bridges and culverts, 85,700 lin. ft. piling, and 425 miles of track-laying. The track was all laid from one end, and in no case were the rails hauled ahead by team. Two iron

cars were used, the empty one on its return being turned up beside the track to let the loaded one by. The tracklaying crew was equal to 4 miles a day. In the month of August, 22 miles of track were laid. The grading forces were scattered along 150 miles ahead of the track. Sidings 1,500 ft. long were graded 7 miles apart.

It will be noted that the grading force averaged 34,000 cu. yds. excavation, 13 M. timber, and 500 ft. piling, per day. Hence each horse, plus $1\frac{1}{2}$ men, averaged 10 cu. yds. per day.

Weight and Cost of Steel in Brooklyn Elevated Railways.*—In 1896 there were about 20 miles of double track elevated railways in Brooklyn, and the average weight of steel was 6,780,000 lbs. per mile, or nearly 1,300 lbs. per lin. ft. This weight was about 28% in excess of what would have been necessary if the columns could have been placed in the roadway; but, due to the narrow streets, fully 4% of the columns were placed at the edge of the sidewalks, necessitating transverse girders 35 to 45 ft. long. The average length of the longitudinal girders was 50 ft. The following is typical of the distribution of the steel in more modern sections (built in 1893), which averaged 7,840,000 lbs. per mile, or nearly 1,500 lbs. per lin. ft., the transverse girders being 45 ft. long:

	Per cent.
Columns	11.5
Transverse girders.....	20.5
Longitudinal girders (two tracks).....	57.0
Station platforms.....	5.0
Bracing	6.0
Total	100.0

This work cost nearly 3 cts. per lb. erected, at which rate the steel work cost nearly \$45 per lin. ft., or less than \$240,000 per mile. Ties 7 x 8 ins., spaced 15 ins. c. to c., were used; guard rails, 6 x 8 ins. The earlier lines were built with 60-lb. rails, but in 1893 rails weighing 85 lbs. were adopted. Stations average 1,800 ft. apart. The locomotives weighed 45,000 to 56,000 lbs., the wheel base being 16 ft.

Cost of the Early Elevated Railways in New York City.*—The cost of a mile of double track elevated railway on Manhattan Island, New York City, up to 1880, when there were 35 miles, is given by Mr. R. E. Johnston as follows:

Foundations, columns, superstr. and track...	\$288,400
Stations	50,000
5 locomotives at \$4,000.....	20,000
12 cars at \$3,300.....	39,600
Total	\$408,000

The foundation pit is 7 ft. square and 7 ft. deep.

**Engineering-Contracting*, Oct. 7, 1908.

The foundation of each column is of brick 4 x 4 ft. on top and 6 x 6 ft. at the base, 4 ft. high, resting on two 6-in. flagstones, 3 x 7 ft. each, which in turn rest on 4 ins. of concrete.

The cast-iron base of the column weighs 3,000 lbs. and is secured by four 2-in. bolts that pass through the foundation.

The longitudinal girders are 44 ft. long.

Nothing was paid for damage to property.

Labor Cost of Track Laying on Elevated Railways in New York City, Also Some Costs of Erecting Steel.*—The following costs relate to track-laying on elevated roads on Manhattan Island, and, although the work was done 28 years ago, the records are given by Mr. G. Thomas Hall in such detail as to be applicable to-day, provided proper substitutions are made for wages.

The Second Avenue line was double track, and about 7.4 miles long, of which about 2% was curved.

The contractors found the following organization the most effective for track-laying:

- 15 carpenters.
- 10 skilled laborers assisting carpenters on the guard timbers.
- 10 men laying steel rails.
- 10 men clipping cross-ties.
- 10 men spacing, marking and edging cross-ties.
- 10 unskilled laborers for derrick, distributing materials, etc.
- 2 horses with drivers.
- 3 foremen.

The clippers were kept 500 ft. ahead of the spikers, and the spikers 750 ft. ahead of the carpenters on the guard timbers. Horsepower was found to be cheaper than steam in hoisting track material from the street. The cross-ties were first hoisted, distributed and spaced; then marked for camber by means of T sights, adzed and clipped. Then the steel rails were in turn distributed, lined up and spiked; then the guard timbers were distributed, ends jointed, gaged and bolted down; the inside guard being put in place and finished with strap iron before the outside one was laid. A space of about 250 ft. intervened between the gangs employed on the two ranges of guard timbers. Everything working smoothly, the above force laid about 260 ft. of double track per 10-hr. day on tangent work.

The following was the cost to the contractor of laying complete 1,000 lin. ft. of straight single track:

Hoisting and distributing materials.....	\$ 40.00
Laying cross-ties	65.00
Laying steel rails	30.00
Laying guard timbers	100.00
Strap ironing guard timbers.....	20.00
Incidentals, loss of time, repairing, tools, etc....	25.00
Superintendence	20.00

Total for 1,000 ft.....\$300.00

The contract prices were 35 cts. to 43 cts. per lin. ft. of single, straight track.

**Engineering-Contracting*, June 2, 1909.

Wages of common laborers were 15 cts. per hr. The above crew of 70 men and 2 horses received about \$145 a day, or practically 20 cts. per hr. per man.

The amount of materials in 1,000 ft. of single track was as follows:

250 cross-ties, 6" x 6" x 12',	9,000 ft. B. M.
500 cross-ties, 6" x 6" x 8',	12,000 ft. B. M.
2,000 wrought-iron clips, $\frac{1}{2}$ " x $2\frac{1}{2}$ " x $5\frac{1}{2}$ ".	
1,500 log screws, $\frac{3}{4}$ " x 6".	
67 steel rails (30'),	63 lbs. per yd.
67 fish plates, $\frac{3}{4}$ " x $2\frac{1}{2}$ " x 20".	
268 fish plates bolts, $\frac{3}{4}$ " x 4".	
2,000 spikes.	
7,000 lin. ft. guard timber, 6' x 8",	28,000 ft. B. M.
1,500 guard rail bolts, $\frac{3}{4}$ " x $14\frac{1}{2}$ ".	
150 log screws, $\frac{3}{4}$ " x 12".	
2,000 lin. ft. strap iron, $\frac{1}{2}$ " x $2\frac{1}{2}$ ".	
200 strap iron bolts, $\frac{1}{2}$ " x $6\frac{1}{2}$ ".	
300 blunt bolts for strap iron, $\frac{1}{2}$ " x 5".	
$\frac{3}{4}$ bbl. Portland cement.	

It will be noted that laying the cross-ties cost about \$3 per 1,000 ft. B. M., and that laying the guard rail cost about \$3.60 per 1,000 ft. B. M.

The cost of 30 cts. per lin. ft. of single track is equivalent to \$1,584 per mile for tracklaying.

To lay one "typical crossing" consisting of two cross-over tracks (one from each main track to a center track), comprising 218 lin. ft. of single track, with 5 frogs, from switches and outside guard timbers, with inside steel guard rails, cost as follows:

Hoisting, adzing and clipping cross-ties.....	\$13.25
Laying rails, frogs and switches.....	40.00
Laying guard timbers.....	12.50
Laying steel guard rails.....	4.25
Total	\$75.00

This is equivalent to 35 cts. per lin. ft. of the single track.

The iron superstructure of this elevated road consisted of Warren longitudinal girders, whose upper chords rest upon the top of Warren transverse girders, supported by six-segment Phoenix columns. The weights were as follows:

	Lbs. per lin. ft.
Transverse girders	200
Longitudinal girders	130
Bracing	8
"A" caliber columns.....	117
"B" caliber columns.....	140

The columns were erected by a gang of 7 men and a team of horses, using a derrick wagon. This gang averaged 39 columns of 20 ft. each, erected per day, or about $4\frac{1}{2}$ tons.

The same gang averaged 10 columns of 50 ft. each, or $3\frac{1}{2}$ tons per day.

The columns were held temporarily in place by inserting iron wedges inside the rim of the base casting.

The cost of placing a 3,200-lb. base casting, on which the column rests, was as follows:

	Per casting.
Uncovering pier (15 cts. per hr.).....	\$0.35
Moving casting from sidewalk to pier (15 cts. per hr.)....	0.40
Erecting derrick and setting casting (15 cts. per hr.)....	0.60
Repaving, 25 sq. ft. (25 cts. per hr.).....	0.50
Washing, tarring and bricking (25 cts. per hr.).....	0.35
Refilling (15 cts. per hr.).....	0.15
Preparing cement mortar (20 cts. per hr.).....	0.10
Foreman and night watchman.....	0.50
Total labor	\$2.95
$\frac{1}{4}$ bbl. cement, at \$1.....	0.25
$\frac{1}{4}$ bbl. sand, at \$1.25 per cu. yd.....	0.05
32 brick, at \$10.....	0.32
$\frac{1}{4}$ cu. yd. refuse carted away.....	0.38
$2\frac{1}{2}$ cu. ft. sand for paving.....	0.11
Coal tar, cement work, etc.....	0.11
Oil for lamps, etc.....	0.05
Grand total	\$4.21

The above is for company work. Later on contracts were let for \$3.75 per 3,200-lb. base casting, and the contractor put in 15 castings a day, as compared with 10 placed by the company's forces.

The girders were erected by a traveler on the structure, with a crew of 12 men and one engineman for the 15-hp. engine, which consumed $\frac{1}{4}$ ton coal per day. This crew raised 66 girders per 10-hr. day, or 200 tons.

The iron girders all being in place, the lateral bracing was then adjusted and riveted, and the columns very carefully plumbed with heavy iron plumb-bobs. Long columns were plumbed with a transit.

Two coats of paint were applied, the first being an iron ore paint and second being white lead. The painting cost \$1.50 per lin. ft. of double track road (not including station buildings), of which 36.8% was for labor.

First Cost and Cost of Operation of Elevated Railways in Brooklyn and New York.*—The following table gives costs of building double track elevated railways in Brooklyn during three different periods:

Year.	1885 to 1888.	1889 to 1891.	1892 to 1903.
Miles of structure built.....	5.6	5.4	3.22
Number of stations.....	14	19	9
Total net tons iron.....	19,488	16,203	10,980 $\frac{1}{2}$
Average net tons per mile.....	3,473	3,001	3,055
Maximum net tons per mile.....	3,578	3,566	3,287
Minimum net tons per mile.....	2,907	2,842	2,824
Cost of iron per ton.....	\$ 79.00	\$ 68.68	\$ 61.00
Cost of each foundation.....	187.70	140.00	93.50
Total cost per mile.....	542.441	322.352	297.599

In explanation of the high cost of foundations it should be stated that, from 1885 to 1888, a brick foundation pier with a bluestone cap

**Engineering-Contracting*, May 6, 1909.

and cast-iron base was used under each post or column. During 1888 to 1891 concrete was substituted for the brick, but the cast-iron base (below the street level) was retained. In 1892 and 1893, the cast-iron base was abandoned, and the columns were designed to rest directly on the concrete at the street level.

The 3.22 miles of structure built in 1892-1893 included 2,800 ft. of third and cross-over tracks, and the following were the average unit prices:

Excavation (per cu. yd.).....	\$ 6.50
Concrete (per cu. yd.).....	7.00
Steel in structure (per net ton).....	\$1.00
Timber (per M).....	21.00
Steel rails per gross ton (85 lbs. per yd.).....	31.00
Labor, laying single track (per ft.).....	0.35

The following gives the detailed costs per mile of structure:

	Per mile of double track.
200 foundations (1,900 cu. yds. concrete) including bolts	\$ 18,649
3,055 net tons iron in place.....	184,423
Double track, materials and labor.....	43,248
Stations	38,819
Engineering	9,924
Miscellaneous	2,526
Total	\$297,599

There are 682,670 ft. B. M. timber per mile, in ties, guard rails, etc., which, at \$21 per M, is equivalent to \$14,357 per mile for timber.

It will be noted that engineering cost 3.35% of the total, and that the average weight of steel in the structure is 1,157 lbs. per lin. ft., and that the average span length of the plate girders is about 53 ft. Considering merely the cost of materials and labor, a span of 30 ft. would have been the most economical, and would have resulted in a saving of 5%, considering only the foundations and superstructure, but the longer span (53 ft.) was adopted to reduce damage to abutting property.

The maximum work of erection in 10 hrs. was 12 spans of 52 ft. each, weighing 315 tons; an average of 8 spans per day was easily maintained.

In the track laid prior to 1888, the ties were 6 x 8 ins., spaced 22 ins. c. to c., and the rails were 60-lb. A 6 x 8-in. guard timber was bolted each side of each rail. In 1888, the ties were made 7 x 8 ins., spaced 16 ins. c. to c., and the rails were still 60-lb. In 1892 an 85-lb. rail was adopted, to secure a longer life of the rail and to reduce the cutting of the rails into the ties, and the ties were spaced 15 ins. c. to c.

The contract prices for stations were about as follows in 1893:

	One stair- way.	Two stair- ways.
Carpenter work	\$3,095	\$3,578
Sheet metal work	1,432	926
Painting and decorating	409	540
Plumbing work	225	296
Heating apparatus	225	295
Architectural work	2,100	2,200
Total	\$7,467	\$7,835

These were ordinary inter-track stations. It is a serious economic mistake to build two stations outside of the tracks, instead of one between, as it doubles not only the first cost but the cost of station service and maintenance. Station service and maintenance cost \$2,400 a year per station.

Terminal stations, containing trainmen's rooms, etc., cost about double the above.

The cost of operating 16.9 miles of double track road, by steam locomotives, in Brooklyn in 1893 was as follows:

Maintenance of Way and Structures:

Repairs of track and structures	\$ 38,816.59
Repairs of stations, shops, etc.	13,032.29
Other expenses	425.30

Total\$ 51,774.18

Maintenance of Equipment:

Repairs of locomotives	\$ 40,317.29
Repairs of cars	53,039.53
Repairs of machinery and tools	1,730.76
Other expenses	11,847.72

Total\$ 106,935.30

Conducting Transportation:

Wages of conductors and guards	\$ 99,343.85
Wages of engineers and firemen	205,180.83
Fuel for locomotives	246,131.53
Oil and waste	6,085.93
Water supply	12,661.38
Other train expenses and supplies	16,585.73
Wages of station agents, gatemen, etc.	158,331.71
Station supplies	7,893.11
Wages of flagmen, switchmen, etc.	25,600.48
Other expenses	67,225.84

Total\$ 845,040.38

General Expenses:

Salaries of officers and clerks	\$ 32,247.56
General office expenses and supplies	809.30
Stationery and printing	6,746.94
Advertising	444.80
Legal expenses	16,574.05
Damage to property	915.08
Damage to persons	14,484.74
Telegraph maintenance and operation	1,195.89
Other expenses	14,695.55

Total\$ 87,963.70

Grand total operating expenses.....\$1,091,713.56

The operating expenses were 56.82% of the gross receipts.

There were 38,110,376 passengers carried.

There were 50 stations in the 16.91 miles.

There were 76 locomotives and 230 cars to operate the 16.91 miles of elevated road. This is equivalent to about 4.5 locomotives and 13.6 cars per mile of road, there being about 3 cars to each locomotive.

In *Engineering-Contracting*, Oct. 7, 1908, the cost of 25 miles of double track elevated railway built on Manhattan Island prior to 1880, was given as follows per mile:

Foundations, columns, superstructure and track	\$288,400
Stations	60,000
5 locomotives, at \$4,000	20,000
12 cars, at \$3,300	39,600
Total	\$408,000

It will be noted that the equipment cost nearly \$60,000 per mile.

If the locomotives and cars cost the same for the Brooklyn lines, it will be seen that the cost of locomotive repairs was 13% of the first cost, for that item amounted to \$530 per locomotive during the year 1893. The cost of car repairs amounted to \$230 per car for 1893, which is about 7% of the first cost.

Our Oct. 7, 1908, issue gives the distribution of steel in the various parts of the Brooklyn elevated railways built in 1893, as follows:

	Per cent.
Columns	11.5
Transverse girders	20.5
Longitudinal girders (two tracks)	57.0
Station platforms	5.0
Bracing	6.0
Total	100.0

It is also stated that the locomotives weighed 45,000 to 56,000 lbs., the wheel base being 16 ft.

Cost of Foundations of the Boston Elevated Railway.—Mr. George A. Kimball gives the following relative to foundations for the Boston Elevated Ry., built in 1899. In general the foundations extend 10 to 12 ft. below the ground surface, to provide against being undermined by subsequent excavations for sewers, building foundations, etc. They are built of concrete in courses 2 ft. thick, stepped up with 6-in. offsets. The top course is 4 x 4 ft., and supports a cast-iron pedestal 12 ins. high to receive the steel post. Most of the foundations were built on the "cost plus a percentage plan." There were 1,133 foundations built, half at a cost of \$260 each, and half at a cost of \$700 each due to soft ground and interference with underground structures. This includes cost of pedestal castings, anchor castings and anchor bolts, which cost \$22 per foundation; it also includes cost of moving underground structures which averaged \$15 per foundation pier. The average foundation cost \$480,

which is equivalent to \$17.50 per lin. ft. of double track structure, or \$91,000 per mile.

It will be noted that these foundations cost five times as much per mile of double track road as those in Brooklyn and New York, indicating extravagant design.

Cost of Elevated Railway and Subway, Berlin, Germany.—In 1901 an electric, double track elevated and subway railway was completed in Berlin, Germany. The motor cars each have two 4-wheel trucks, with axle loads of $6\frac{1}{2}$ tons, axles being spaced 5.9, 15.0, 5.9 and 11.2 ft., in sequence. The weights of steel in different portions of the double track elevated road were:

Span, ft.	Lbs. per lin. ft.
39.4	810
49.2 (at stations, but not incl. stations)....	1,145
54.1	940
68.9	1,210

There are 5.15 miles of double track elevated line and 1.22 miles of subway. There are 10 stations on the elevated portion and 3 in the subway.

The main power plant building is 73 x 132 ft., and houses 3 compound engines, each developing 900 hp. normally, or 1,200 hp. maximum. Trains are run on $2\frac{1}{2}$ to 5 min. headway, at a maximum speed of 30 miles per hour. Each train consists of 3 cars (each 40 ft long), two of which are motor cars.

The cost was:

Construction	\$4,400,000
Power house, rolling stock, equipment.....	950,000
Extras	500,000
Interest during construction.....	500,000
Total	\$6,650,000

The construction cost of \$4,400,000 was distributed thus

1.221 miles double track subway, at \$860,000....	\$1,050,000
5.154 miles double track elevated, at \$650,000...	3,350,000
6.375 miles total.....	\$4,400,000

There were about 13,000 tons of steel used in the elevated (including stations), which is equivalent to about 1,320 lbs. per lin. ft. of double track elevated. The contract price on this work ranged from 3 to $4\frac{1}{4}$ cts. per lb. erected.

There were 2,200 tons of steel used in the subway.

Some of the other contract prices were:

	Per cu. yd.
Concrete in subway.....	\$4.60
Brick foundation masonry.....	5.25
Arch masonry	7.85

It will be noted that the power house and equipment cost about 15% of the total cost, and amount to about \$150,000 per mile of double track railway.

Cost of New York Subway Rock Work.*—By observation and through the aid of an assistant I have secured reliable data relating to every item of cost on several typical sections of the New York Rapid Transit Ry., including excavation, concrete, steel construction, etc.; and it is astonishing to find how high the labor cost of the work has been. The high cost may be attributed to several causes. In the first place, the contractors were compelled to employ union labor, much of which was inefficient. In the second place the foremen on this work were, as a rule, paid such small salaries that the best class of foremen were not kept. In the third place excavation and other work in crowded city streets is obviously made difficult; the supporting of pipes, tracks, etc., adding greatly to the cost in certain parts of the city. In fact, in the lower part of New York, where the material is all sand, I have found that 50 cts. per cu. yd. has been expended in shoring, bracing, etc. In the fourth place the light blasts required by city rules leave the tough mica schist in large chunks upon which much labor must be expended in gadding and sledging; for practically all the rock was broken to one or two-man size so that it could be hauled away in dump wagons.

The work that I am about to describe involved the excavation of about 125,000 cu. yds. of tough mica schist in the upper part of the city, where the streets are not crowded and where there were very few pipes to be supported. The width of the excavation was 41 ft., and the depth averaged about 30 ft. One trolley track ran along the center of the street and had to be supported the entire distance. This track supporting was accomplished at comparatively slight expense by using some ten second-hand railroad bridge trusses of 66 ft. span, which were moved forward as the work progressed. Five cableways, each having an average span of 400 ft., were used for hoisting the rock in self-righting buckets, which were dumped into patent dump wagons.

The average daily force employed was as follows:

	Rate per day.	Total
4 foremen	\$3.50	\$ 14.00
80 laborers ..	1.50	120.00
10 drill runners	2.75	27.50
10 drill helpers	1.50	15.00
2 blacksmiths ..	2.75	5.50
2 blacksmiths' helpers ..	1.50	3.00
5 holsters	3.00	15.00
1 compressor man	4.00	4.00
1 fireman	2.00	2.00
2 timbermen	2.00	4.00
3 waterboys75	2.25
20 teams	4.50	90.00
Total per 8-hr. day.....		\$302.25

*Gillette's "Rock Excavation," p. 273.

The average output of this force was only 150 cu. yds. of rock per day.

	Wages per 8-hr. shift.	—Cost per cu. yd.	
		Average of 30 months.	Best month.
Drill runners	\$2.75	\$0.174	\$0.150
Drill helpers ..	1.50	.100	.082
Blacksmiths	2.75	.032	.025
Blacksmiths' helpers	1.50	.018	.012
Compressor man	4.00	.016	.014
Firemen	2.00	.012	.014
Hoist enginemen	3.00	.100	.051
Carpenters	3.50	.008	.000
Timbermen	2.00	.024	.000
Waterboys	0.75	.012	.010
Laborers	1.50	.785	.745
Foremen	3.50	.102	.095
Teams (with drivers).....	4.50	.620	.581
Total wages		\$2.002	\$1.779
Cu. yds. excavated.....		125,000	7,600

To the foregoing must be added the cost of fuel, explosives, maintenance, interest and depreciation of plant, etc., as follows:

	Cost per cu. yd.
1/30 ton coke, at \$4.50.....	\$0.150
0.6 lb. 40% dynamite, at 12½ cts.....	0.075
¼ exploder, at 4 cts.....	0.020
Drill repairs (est'd at 50 cts. a day per drill) ..	.034
Installing boiler and compressor.....	.014
Interest and depreciation (50%) of \$7,000 boiler and compressor plant.....	.028
Ditto for \$3,500 drilling plant.....	.014
Total supplies, etc.....	\$0.335
Add total wages.....	2.002
Total	\$2.337

To this sum should be added 3 or 4% to cover general expenses, such as office rent, bookkeeping, night watchmen, insurance on laborers, etc., which would bring the grand total to nearly \$2.40 per cu. yd. of rock excavated. It will be seen by the description of the work and by the comparatively low cost of timberwork that the expense of supporting pipes and tracks was unusually low for such a city as New York. On the other hand, the cost of drilling was exceedingly high, being 28 cts. per cu. yd. for wages alone, if we include the blacksmiths' wages and half the wages of the compressor man and his fireman. The drills should be charged with about half the cost of the fuel, which adds 7½ cts. more per cu. yd., making 35½ cts. per cu. yd. for drilling, not including some 3½ cts. for drill repairs (estimated) and 1½ cts. for interest and depreciation. Adding these two items we have a total of 40 cts. per cu. yd. chargeable to drilling alone, which is exceedingly high for an open cut of this width and depth. It is a striking fact that each drill broke less than 15 cu. yds. of rock per 8-hr. day. The inefficiency of the laborers is also well shown by their output of less than 2 cu. yds. per man per 8-hr. day. It is true that they had to

do a great deal of gadding, sledging and hand drilling to break the rock ready to load into buckets; but anyone who saw the men at work must have been impressed with their slowness. The output of only 30 cu. yds. per day per cableway shows how the cableway output was limited by the drilling. The high cost of hauling is also noteworthy, for the average haul was but little more than one mile.

While it was difficult to get union laborers to do a fair day's work, I think that if the contractors along the subway had in all cases employed civil or mining engineers of known experience in rock excavation, a great deal of money would have been saved.

Cost of New York Subway Earthwork.*—This is a class of work exceedingly expensive, not only on account of the work of supporting of pipes, buildings and car tracks, but because of the comparatively small gangs that must be worked. This not only runs up the cost of superintendence, but due to the great number of foremen employed, many bosses are exceedingly inefficient. While the laborers receive high wages (1.50 for 8 hrs.), it will be noted that the foremen are paid altogether too low salaries to secure the best of their class. A good superintendent of railway excavation frequently receives \$250 a month, and if he is worth anything, he is worth that. On extensive excavation, cheap foremen mean dear work, as the following illustrates quite clearly:

Case I. Uptown, where the streets were not congested. Soft earth, ploughed, loaded with shovels into patent dump wagons, hauled half a mile and dumped; 1.9 cu. yds. place measure per wagon load. Excavation 55 ft. wide, in the street, and ultimately 20 ft. deep. Snatch teams and hoisting engine used to pull loaded wagons out of the pit. Delays in hauling due to street blockades. Numerous pipes and conduits to be supported, necessitating carpenters, plumbers, etc. The following gives the cost for one month's work, including tearing up pavement:

Laborers	1,130 days at \$1.50	\$1,695.00
Teams, hauling and plowing.....	520 days at 4.50	2,340.00
Snatch teams	30 days at 5.00	150.00
Carpenters	180 days at 2.50	450.00
Engineman	22 days at 2.75	60.00
Fireman	22 days at 2.00	44.00
Engineman (night)	22 days at 2.00	44.00
Superintendent		100.00
Foremen	69 days at 2.00	177.00
Two timekeepers and load checkers.....		135.00
Three watchmen	78 days at 1.50	117.00
Plumbers, caulkers, etc.....		300.00
Total for 8,400 cu. yds. at 88 cts.....		\$5,612.00

The foregoing cost was at the beginning of the work, and under what might be regarded as favorable conditions. The following gives the general average of several jobs at a later period, and may be taken as being under, rather than over the actual cost, because all timber work and incidentals are probably not included:

*Gillette's "Earthwork and Its Cost," p. 176.

Case II. Conditions same as in Case I, except that excavation, car tracks, etc., required more support.

	Per cu. yd.
Labor excavating and superintendence.....	\$0.50
Teaming	0.10
Materials and supplies.....	0.09
Labor on bracing and sheeting.....	0.06
Materials for bracing and sheeting.....	0.07
Labor on bridges and barricades.....	0.01
Materials for bridges and barricades.....	0.01
Taking up pavement	0.01
Labor for pumping and draining.....	0.02
Materials for pumping and draining.....	0.01
Labor on engines.....	0.04
Fuel for engines.....	0.01
Total	\$1.23
Hauling away in scows.....	0.32
Grand total	\$1.55

A charge of 60 cts. per wagon load, which was equivalent to 32 cts. per cu. yd. (as above recorded), was made for removing the earth from the water front on scows.

The subcontractor's prices for this earthwork averaged about \$2 per cu. yd. On some sections as high as \$2.50 per cu. yd. was paid, and in those sections the contractors found that it cost them \$25 per lin. ft. of street to keep the car tracks in shape, due largely, however, to poor methods of management.

On downtown work, where the streets were not entirely torn up, but were kept planked over so as not to interfere with traffic, the cost of earth excavation was \$2.65 per cu. yd. (See the following paragraphs.)

Itemized Cost to the Contractors of the New York Subway for Earth and Rock Excavation, Bracing, Concrete, Waterproofing and Steel Work.* -In view of the fact that the City of New York will doubtless construct scores of miles of subways for rapid transit, any data of actual cost of construction will be of great value to contractors and subcontractors who may bid upon subway work in the future. Then, too, other large cities will surely be forced to build subways similar to those in New York and Boston.

We have secured complete itemized records of the actual cost of labor and materials required to build several sections of the subway in New York City, and these records are now published for the first time.

We shall first give the methods and costs of building a half-mile section from the Post Office to the Battery. The excavation work was not done by the "cut and cover method"; that is to say, a trench was not dug in the street and left entirely open, as was the practice on nearly all subway work between the years 1902 and 1904. So much of a hue and cry had been raised against the open-cut method that when the contract for the Brooklyn Extension was drawn, the contractors were required to keep the streets continuously open for traffic, except at night time.

**Engineering-Contracting*, Feb., 1906.

To meet this requirement the contractors devised the following method of operation: In the night time a short section of the street pavement was removed, stringers were laid down, and a plank roadway was laid upon the stringers. Then the excavation was proceeded with, underneath this plank roadway. In order to make the excavation, small shafts were sunk through the sidewalk at intervals of about a quarter of a mile. Through these shafts all excavated materials were removed and all construction materials were taken in.

Fig. 10.—Excavation, New York Subway.

At each shaft a temporary bridge was built (Fig. 10) spanning the street, and upon this bridge were mounted the derricks and hoisting engines. Each overhead bridge consisted of a 52 × 60 ft. wooden platform carried by I beams, the whole supported by well-braced timber trestles set upon each curb line, as shown below. Each platform carried two stiff-leg derricks set opposite each other, also a hoisting engine and a spoil-bin with chutes. The derricks were operated during the daytime by compressed air, but at night the necessary power was supplied by a vertical boiler on one platform and an electric motor on the other.

The work of substituting timber platforms for street pavement was begun at the overhead bridges. Small strips of pavement

were removed at each end of the platform and shallow excavations made in which trenches were dug. Longitudinal 24-in. I beams were placed in each trench and blocked up on the trench bottom. The paving between the trenches was then taken up and a layer of earth removed to make room for the timber platform. This was composed of 8-in. I beams, spread $7\frac{1}{2}$ ft. apart, with their ends resting on the girders. On this was placed 6-in. roadway planking. All this work was done at night and in such short sections that the street could be restored before daylight.

After the first section of platform had been built, a shaft 8 ft. square was sunk through the west sidewalk to a depth of 10 ft. From this shaft the upper part of the excavation was tunneled under the platform, the longitudinal girders being supported by posting down as the work progressed. Similar posts and blocking were placed under the street railway. When sufficient headway had been secured, shafts 5 ft. square were sunk to the subgrade of the subway. A portion of the concrete floor of the subway was built in the bottoms of these shafts and a post erected to carry the girders. The temporary blocking under the railway conduits was then removed and replaced by saddle beams strung from the girders.

An alternative method for carrying the tracks and street surface was used where the excavation was obstructed by pipes and conduits. Surface platforms were built on each side of the street between the curb and the nearest street railway conduit. A lateral drift was then carried under the conduit and a needle beam inserted. These beams, which were blocked up against the conduit, carried on their outer ends longitudinal I beams which supported the inner edges of the surface platforms. The other edge of these platforms rested on the I beam girders supported by the blocking in the trenches at the curbs. After the earth between the drifts was removed, the needle beam shores were reinforced by jacks resting on continuous longitudinal sills. The posts were then set in shafts and replaced the jackscrews and blocking.

All of the excavated material was taken to the shafts and hoisted by the derricks to the overhead platform, where it remained until discharged through the chutes into wagons on the street below. The excavation was done by pick and shovel, cars being used to transport the material to the nearest shaft. These cars were either pushed by the laborers or drawn by a mule. The excavated material was sand, for the most part, very easy to dig. Indeed, much of the sand was used for concrete.

In the following tabulation is given the actual unit cost to the contractor of the construction of a section about one-half mile long of the Brooklyn Extension of the Rapid Transit subway of New York City. The period covered by these costs extends over sixteen months:

EARTH EXCAVATION.

(112,288 cu. yds.)

	Per cu. yd.	Total.
Labor	\$1.60	\$179,998
Materials and plant.....	0.32	35,590
Power	0.02	2,678
Dump charges (60 cts. per load).....	0.25	27,934
Total unit cost.....	\$2.19	
Grand total cost.....		\$246,198
<i>Bracing and Sheet-piling:</i>		
Labor	\$0.78	\$ 87,466

Grand total unit cost	\$0.06	
Grand total cost		\$ 7,756

WATERPROOFING.

(98,074 sq. yds. single ply.)

Labor	\$0.05	\$ 5,563
Materials and plant	0.10	9,703
Grand total unit cost	\$0.15	
Grand total		\$ 15,265

WATERPROOFING.

(Brick in asphalt 1,337 cu. yds.)

Labor	\$ 6.32	\$ 8,457
Materials and plant	11.48	15,351
Grand total unit cost	\$17.80	
Grand total cost		\$ 23,808

The following table gives a summary of the total costs from August, 1903, to January 1, 1905, of constructing this section. In the preceding table no unit costs are given on the work of underpinning buildings, blocking, moving and relaying mains, supporting tracks, paving, station work, track work in tunnel and construction of a cross passage in Dey street. The net totals of these, however, are figured in with the other totals in the summary:

SUMMARY.

Labor	\$443,268.13
Materials and plants.....	232,723.30
Dump charges (46,555 loads at 60 cts.)....	27,933.60
Power (coal and electricity).....	4,373.95
Labor charged to sewers.....	2,803.80

Total cost (not incl. cost of steel and iron). \$711,102.58

This is for half a mile of double track line.

During the excavation the contractor sold 12,924 cu. yds. of sand at 50 cts. per cu. yd., and 1,520 cu. yds. rubble stone at \$1.00 per cu. yd. Deducting this total of \$8,082 from the total cost of the work we have \$703,020.58 as the net cost of the work, exclusive of the cost of the steel in posts and beams. The cost of track and ballast is not included, but that is readily estimated.

It will be noticed that in the tables giving the unit costs of the subway construction one of the main items is for materials and plant. In the following tabulation are shown the principal items and their cost which composed materials and plants:

MATERIALS AND PLANTS.

Earth Excavation:

	Total.
Small tools, etc.....	\$ 529
Illumination, etc.	3,119
Boilers, total 210 hp.....	2,600
37 1 cu. yd. buckets.....	2,200
11 stiff leg derricks.....	2,750
20 flat cars	400
4,600 lin. ft. rail tram....	306
2 Rand drills.	600
2 Dake engines.....	700
3 Lidgerwood engines.....	1,680
3 electric hoists, "Maine".....	3,750
1 electric hoist, "Lidgerwood".....	1,500
166 M. ft. yellow pine lumber at \$25.....	4,155
208 tons steel beams, in working platforms....	10,470
Miscellaneous	550
Total	\$35,590

Rock Excavation:

4 Rand rock drills.....	\$ 1,200
1 Lidgerwood engine.....	560
1 stiff-leg derrick.....	250
760 lbs. dynamite.....	114
Small tools, etc.....	130
Total	\$ 2,254

Bracing and Sheeting.

2 Rand drills (without at.) for driving sheeting.	\$ 500
24 hydraulic jacks, 1,264 tons capacity	4,049
1,436 M. ft. yellow pine lumber at \$25	35,900
Small tools, etc.	767

Total\$41,216

Pumping and Drainage:

5 Worthington pumps	\$ 770
1 Lawrence pump	350
2 Edison diaphragm No. 3 pumps	45
5 pumps, steam syphons	100
Small tools	6

Total\$ 1,271

Bridges and Barricades.

607 M. ft. yellow pine lumber	\$15,187
Small tools, etc.	236

Total\$15,423

Underpinning Buildings and Vaults:

1,323 cu. yds. rubble stone	\$ 1,323
225 cu. yds. sand	112
872 bbls. Portland cement	1,378
165 gallons asphalt	19
442 sq. yds. asphalt felt	19
16 M. brick	115
124 gallons paint	124
Small tools, etc.	37

Total\$ 3,132

Roof and Side Arch and Protection Concrete:

3,248 cu. yds. sand	\$ 1,624
4,296 cu. yds. gravel	6,874
8,095 bbls. Portland cement	12,790
36 M. ft. yellow pine lumber at \$25	900
371 M. brick	2,599
Small tools, etc.	276

Total\$25,064

Brick Backing:

34 cu. yds. sand	\$ 17
130 bbls. Portland cement	205
81 M. hollow tile brick	1,785
Small tools, etc.	56

Total\$ 2,063

Duct Laying:

6,000 sq. yds. burlap	\$ 270
123,483 lin. ft. single ducts	5,556
275 bbls. Portland cement	435
68 cu. yds. sand	34
13 sets mandrels	28

Total\$ 6,321

Waterproofing, Brick Laid in Asphalt:

869 M. brick	\$ 6,083
401 tons mastic asphaltum	9,025
Small tools, etc.	243

Total\$15,351

Waterproofing:

112,785 sq. yds. asphalt felt.....	\$ 5,675
36,582 gallons asphalt.....	4,389
Small tools, etc.....	237

Total\$ 9,702

Placing and Riveting Steel Work:

2 "Lidgerwood" engines	\$ 1,120
2 air compressors and receivers.....	1,400
1 hand power derrick	50
1 pneumatic drill	125
4 riveting guns	500
Small tools, etc.....	763

Total\$ 3,958

Painting Steel:

376 gallons cerion paint.....	\$ 376
Brushes and scrapers..	39

Total\$ 415

Supporting Tracks:

Sand, stone and cement.....	\$ 301
68 M. brick.....	474
20 hydraulic jacks, 1,050 tons capacity.....	3,412

Total\$ 4,184

Block, Moving and Relaying Mains:

199 M. ft. yellow pine lumber at \$25.....	\$ 4,985
2 hand derricks	100
1 portable derrick, with boiler and engine.....	1,000
Pipe	26,186
Gates, valves and lead.....	1,371
Small tools, etc.....	1,699

Total\$36,841

Grand total for plant and materials.....\$232,723

We note that the cost of placing and riveting steel is given, but nothing is said as to the cost of the steel itself. The price of steel delivered in New York, ready for erection, may be estimated at $2\frac{1}{2}$ cts. per lb., or \$50 per ton. As there were 1,532 tons of steel, the total cost of the steel was \$76,650. In addition, there were 171 tons of castings, which, at \$40 per ton would amount to \$6,840, and there were 1,014 cu. yds. of brick backing, the bricks for which would cost about \$14 per cu. yd., or \$14,200. The sum of these three items is \$97,690 to be added to the \$711,102 above given, making a total of nearly \$810,000 for the section under consideration—half a mile of double track subway.

It will be seen that the full first-cost of the plant has been charged up against the various items. The cost of renewals of wornout parts was not obtainable, so that the only satisfactory method of estimating plant charges consisted in including the full cost of the plant.

In some items, as in Rock Excavation, the cost of plant is altogether too high, due to the fact that an expensive plant is charged up against a small amount of work.

It will be noted that the pumping item was very small; so also is "backfilling," because most of the excavated material was hauled away. The backfill was 6 ft. deep over the subway roof. All the excavated material not used for concrete or masonry, was hauled away in wagons to the docks, the haul being very short (about $\frac{1}{2}$ mile) to the docks where the material was dumped into scows and hauled to sea. The charge made for hauling to sea in scows ("dump charges") was 60 cts. per wagon load, and about $1\frac{1}{2}$ cu. yds. of earth constituted a load.

The total cost of earth excavation was \$3.62 per cu. yd., which seems very high. However, the conditions must be considered, and among other things it must be remembered that the cost of supporting numerous water pipes and gas pipes is included. The excavation was 26 ft. deep, and 34 ft. wide along the line between stations.

The cost of power charged to the various items includes only the fuel and electricity consumed. Electricity was paid for at 4 cts. per kw.-hour.

All steel was painted with one coat of carbon paint; and all steel not imbedded in concrete received, in addition, a coat of white lead paint.

The cost of waterproofing is reduced to cents per square foot of single ply; but the waterproofing was actually laid 2 to 3 ply thick.

For the sake of comparison, we shall next give a summary of the costs of earth excavation on two sections in the lower part of New York City, where the open cut method of excavation was used. The rates of wages were practically the same as in the table on page 33; but the work was done between the years 1902 and 1904. The excavation was wider, being for a four truck road, and cableways were largely used for delivering the materials from the trench into wagons. Some derricks were also used for this purpose. The streets were not always opened their full width, which necessitated a good deal of mining under the pavements and car tracks. The costs of excavation by this open-cut method were as follows on two sections which are designated as Contract A and Contract B.

	Contract	
	A.	B.
Cu. yds. excavation.....	105,070	252,870
Labor and teaming.....	\$1.15	\$1.20
Plant (all of first cost).....	0.17	0.14
Power	0.12	0.09
Dump charges, at 60 cts. per load of 1½ cu. yds.	0.19	0.18
Labor and bracing and sheeting.....	0.34	0.18
Lumber for bracing and sheeting.....	0.21	0.11
Pumping and draining.....	0.00	0.06
Labor on bridges and barricades.....	0.02	0.02
Lumber for bridges and barricades....	0.03	0.04
Labor, backfilling.....	0.06	0.04
Total per cu. yd.....	\$2.30	\$2.06

The contractor, in each case, sold enough sand from the excavation to reduce the cost of excavation about 18 cts. per cu. yd., leaving a net cost of \$2.12 for Contract A, and \$1.38 for Contract B. The sale of this sand also reduced the dump charges, which would otherwise have been 36 cts. per cu. yd., instead of 18 to 19 cts. Had all the material been hauled to sea, the dump charges would have added about 18 cts. per cu. yd., making a cost of \$2.48 for Contract A, and \$2.24 for Contract B. It should be noted, however, that the full amount of the first-cost of the plant was charged against the excavation. The item of backfilling is not large because so small an amount of excavated material was replaced.

The lumber for bracing and sheeting was about half spruce, at \$20 per M., and half yellow pine, at \$25 per M.

The labor and teaming includes all wages and salaries.

The cost of erecting, riveting and painting the steel work was \$16 per ton on Contract A, and \$16.75 on Contract B.

The cost of labor in making the concrete was as follows:

Concrete foundations:

	Contract A.	Contract B.
Labor, mixing.....	\$0.97	\$0.94
Labor, placing.....	0.96	0.95
Power	0.14	0.16
Total	\$2.07	\$2.05
Concrete, Roof and Sides.		
Labor, mixing.....	\$0.79	\$0.91
Labor, placing.....	0.85	0.94
Labor, setting forms.....	2.01	1.20
Labor, plastering arches. . .	0.16	0.23
Power	0.28	0.15
Total	\$4.09	\$2.43

It will be noted that these concrete labor costs are very high, and indicate poor management.

As to the cost of rock excavation, we may say that it should not exceed the cost of earth excavation by more than \$1 per cu. yd. at the outside. Indeed, on one section of the subway involving the excavation of 125,000 cu. yds., the rock excavation cost \$2.40 per cu. yd., but this did not include the first cost of the plant. In Gillette's "Rock Excavation," page 273 et seq., the actual cost of this rock work is given in great detail. (See page 1384.)

With the unit costs now available, any contractor can make a safe estimate of the cost of any future subway work in New York City. If the subway is built wider or narrower, the yardage will be altered, but the cost per cubic yard will not vary much. We are confident that few contractors or engineers would have looked for such high unit costs as are above given, and we are equally confident that with better management the costs could have been materially reduced. However, it is a fact and not a theory that confronts us, and we have given the facts to the best of our ability.

In the summary given above, the total cost of the labor from August, 1903, to January 1, 1905, is given as \$446,071.73. It will

be of interest to show how this cost was distributed, and accordingly a table giving the rate of wages per eight-hour day, the time in days, and the total amount of wages is appended in Table XXV.

TABLE XXV.—RATE OF WAGES AND TIME.

	Rate.	Time.	Amount.

Cost of Excavating and Bracing a Subway, Long Island R. R., Brooklyn.*—The work covered by our cost records was a section on

*Engineering-Contracting, July 11, 1906.

and diagonally from the side of each cross brace to the middle of the ranger. These angle braces were about 14 ft. long.

The railroad company provided the cars and hauled the earth about 12 miles away, furnishing train crews. The contractor maintained and shifted the tracks, loaded the earth onto the cars, and did all the bracing. The following costs were the costs to the contractor, and do not include the cost of hauling the material away. The contractor complained of the poor train service furnished by the company, and the high cost of excavating bears out his claim of poor service. On the other hand, the railroad company is credited by outsiders with having given a "fair service." In any case, work done in this manner is nearly always subject to more or less delay in getting empty cars fast enough.

As above stated, the length of subway covered by our cost records was about 2,500 ft., averaging about 30 cu. yds. per lineal foot. A total of 75,000 cu. yds. were excavated in the year 1908,

Fig. 12.

requiring 20,900 days' labor, or 3.6 cu. yds. per man per 10-hour day. Wages averaged \$1.50 per day, making the average cost 42 cts. per cu. yd. for loading the cars. This does not include the cost of sheeting and bracing, which will be given later. The cost of the excavation by months was as follows.

EXCAVATION.				
	Amount cu. yd.	Labor in days.	Pay-roll.	Cost per cu. yd.
January	4,818	1,637	\$ 2,278	\$0.47
February	4,089	1,433	1,992	0.49
March	11,005	2,554	2,552	0.23
April	5,381	1,508	2,132	0.40
May	4,230	1,321	1,844	0.44
June	3,035	1,127	1,573	0.52
July	4,002	890	1,379	0.35
August ..	5,883	1,654	2,617	0.49
September	8,118	2,450	4,307	0.54
October	10,327	2,392	3,658	0.35
November	8,550	1,930	3,023	0.35
December	5,953	1,838	3,083	0.52
Total	74,891	20,905	\$31,438	\$0.42

The cost of labor sheeting and bracing was as follows:

SHEETING AND BRACING.

	Labor days.	Pay-roll	Cost per cu. yd.
January	507	\$ 1,092	\$0.23
February	482	1,091	0.27
March	827	1,766	0.16
April	874	1,859	0.35
May	782	1,859	0.42
June	860	1,999	0.66
July	1,005	2,363	0.59
August	812	1,894	0.35
September	700	1,613	0.20
October	800	1,831	0.18
November	644	1,510	0.18
December	1,316	1,742	0.29
Total	9,609	\$20,548	\$0.27 1/2

It will be seen that the average wages paid for sheeting and bracing were \$2.13 per day. As above given, the labor cost of excavating was 42 cts. per cu. yd., to which must be added the 27 1/2 cts. per cu. yd. spent for labor on sheeting and bracing, making a total of 69 1/2 cts.

The amount of timber used in sheeting and bracing the work done in 1902 and 1903 was as follows:

Between stations.	Ft. B. M. sheeting.	Rangers, braces, angles and uprights.
143 and 115.....	348,320	498,440
115 and 112.....	14,740	24,030
101 and 92.....	57,320	115,520
87 and 91.....	17,820	9,620
Total	388,200	647,610

This makes a grand total of 985,810 ft. B. M., or 7.94 ft. B. M. per cu. yd. of excavation, or 263 ft. B. M. per lin. ft. of finished subway, 3,700 ft. long.

From these data it is apparent that practically all the timber was left in place until the completion of this section of the subway. It is also apparent that the yardage of earth excavated in 1902 and 1903 was about 124,300 cu. yds. It should be borne in mind, however, that the labor costs above given for excavation and bracing include only the work done in 1903. The labor of sheeting and bracing for the two years was as follows.

Year.	Labor days.	Pay-roll.
1903.....	9,609	\$20,548
1902.....	4,290	9,870
Total.....	13,899	\$30,418

From this it appears that the labor costs of framing and placing the 985,810 ft. B. M. was \$30.80 per M., and that each man averaged only 71 ft. B. M. per day. This is a very high cost for such work.

Since the timber itself must have cost approximately \$30 per M. delivered on the work, we have the following estimate of the total cost of excavating:

	Per cu. yd.
Labor loading cars.....	\$0.43
Labor sheeting and bracing..	0.27 $\frac{1}{2}$
7.94 ft. B. M. timber at 3 cts. .	0.24
Total	\$0.93 $\frac{1}{2}$

Of course, much of the timber would possess some salvage value after completing the work.

The cost of hauling the material away in cars and dumping is not available.

The cost of the concrete work was as follows:

Cement.	Proportions by parts.			Bbls. cement per cu. yd. concrete.
	Sand.	Gravel.	Broken stone.	
1	3	2 $\frac{1}{2}$	2 $\frac{1}{2}$	0.75
1	3	0	5	1.07 to 1.14
1	4	1 $\frac{1}{2}$	2 $\frac{1}{2}$	1.12
1	4	2	2	1.16
1	4	0	4	0.98
1	4	1	3	1.07
1	2 $\frac{1}{2}$	0	3 $\frac{1}{2}$	1.26
1	3	0	3	1.20
1	2 $\frac{1}{2}$	1 $\frac{1}{4}$	2 $\frac{1}{4}$	1.46
1	3	1	2	1.30
1	3	1 $\frac{1}{2}$	1 $\frac{1}{4}$	1.04

It is interesting to note that in mixing many thousand yards of 1:3:5 concrete, it took 1.07 bbls. cement when mixed in the gravity mixer, as compared with 1.14 bbls. for the batch mixer, indicating a less perfect mixture in the gravity mixer.

Of the "1 to 8" concrete, about 13,880 cu. yds. were placed during the year of 1903, months of January to November inclusive, and 90 per cent of this was mixed with gravity mixers.

Of the "1 to 6" concrete, 5,320 cu. yds. were placed, of which 85 per cent was mixed with gravity mixers. The remainder, in both cases, was mixed in a "batch mixer."

The average size of a batch in a gravity mixer was 0.46 cu. yd., and the size of batch in the "batch mixer" averaged about 0.57 cu. yd.

There were 16,940 cu. yds. mixed in gravity mixers, requiring 2,860 days' labor mixing and 4,000 days placing the concrete. Wages were \$1.50 a day, and the cost was 26 cts. per cu. yd. for mixing and 33 cts. for placing, making a total of 59 cts. per cu. yd.

During the month of August, when 2,800 cu. yds. were mixed, the cost was as low as 24 cts. for mixing plus 22 cts. for placing, making a total of 46 cts. per cu. yd. for mixing and placing. The gravity mixer averaged about 113 cu. yds. per day, with a gang of 19 men mixing and 26 men placing concrete.

With the "batch mixer," which averaged about 0.57 cu. yd. of concrete per batch, there were mixed 2,360 cu. yds. This required

970 days of laborers mixing and 740 days placing, at a cost of 59 cts. per cu. yd. for mixing plus 45 cts. for placing, making a total of \$1.04 per cu. yd. for mixing and placing.

During the month of June the cost was as low as 40 cts. for mixing and 30 cts. for placing, or a total of 70 cts. per cu. yd., wages being \$1.50 per day. The average gang was 14 men mixing and 11 men placing the concrete, and the average output was only 35 cu. yds. per day actually worked.

Even during the month of June, when the best record was made, the output was only 52 cu. yds. per day actually worked. This indicates very poor management. We refrain, therefore, from giving the name of the "batch mixer," to which an injustice would be done if its efficiency were rated according to this particularly poor record.

Of course, in the preceding discussion of the itemized labor cost of mixing and placing, the item of "mixing" includes all the work involved in delivering the materials to the mixer; while "placing" includes hauling the concrete away from the mixer.

In delivering the materials to the gravity mixer a Robins belt conveyor was used, which accounts in large measure for the lower cost of mixing with the gravity mixer.

The concrete was hauled away from the mixers in dump cars pushed along a track by men. The track was laid on top of the braces that supported the sides of the excavation. We are unable to find out why the conveying of the concrete from the batch mixer cost so much more than from the gravity mixer.

The foregoing costs relate to work done in 1903. During the year 1904, 20,000 cu. yds. were mixed in the 190 days worked by the gravity mixer gangs; the average number of men mixing being 15, and the number of men placing being 25.

The cost was as follows:

	Cts. per cu. yd.
2,950 days labor mixing, \$4,870.....	34
4,760 days labor placing, \$7,300.....	36
Total	60

During the best month, the labor cost was 16 cts. for mixing and 29 cts. for placing, or a total of 45 cts. per cu. yd.

During the same year of 1904, the batch mixer worked 153 days, averaging 46 cu. yds. per day. The average size of each batch was 0.44 cu. yd. The labor cost of 7,000 cu. yds. was as follows.

	Cts. per cu. yd.
1,910 days mixing, \$3,175.....	45
1,740 days placing, \$2,660.....	38
Total	83

It will be noted that in 1904 the cost of placing was practically the same as with the gravity mixer, and that the average gang on the batch mixer was 13 men mixing and 11 men placing.

Thus far we have not considered the cost of the labor on the forms, which was a large item. For the total 19,300 cu. yds. of

concrete placed in 1903 there were expended \$16,800 for labor on the forms, which is equivalent to 87 cts. per cu. yd. of concrete. The total number of days' labor on the forms was 6,340, at an average of \$2.70 per day. If we add this 87 cts. per cu. yd. for labor on forms to the 59 cts. for mixing and placing, we have a total of \$1.46 per cu. yd. chargeable to labor on the concrete in this subway, where a gravity mixer was used. This is considerably below the cost of similar work on the New York subway.

As to the amount of lumber in the forms and the interest and depreciation of the plant, we have no record. Nor have we a record of the fuel consumed.

Cost of Cable Railways in Cities.—In Fairchild's "Street Railways" (1892), the following is given as an estimate of the cost of a double track cable line, based upon actual cost of some six lines. The line is 3 miles long.

	Total.	Per mile of double track.
Power House and Plant:		
Real estate	\$ 10,000	\$ 3,333
House, 100 x 175	25,000	8,333
Two engines and foundation	23,000	7,667
Boilers and settings	14,000	4,667
Brick smokestack (5 ft. diam. x 100 ft)	5,000	1,667
Tension cars and tracks	2,500	833
Heaters, pumps, fittings, etc.	3,000	1,000
Total power house and plant	\$ 82,500	\$ 27,500
General Street Construction.		
19,800 cu. yds. trench excavation at \$0.75	\$ 11,850	\$ 4,950
2,755,000 lbs. cast yokes (350 lbs. ea.) at \$0.015	41,580	13,860
880 carrying sheaves at \$3.75	3,300	1,100
1,056,000 lbs. slot rails (50 lb.) at \$0.025	26,400	8,800
1,185,000 lbs. truck rails (60-lb) at \$0.0225	28,512	9,504
154,000 lbs. cast iron manhole covers and frames at \$0.0175	2,695	898
10,000 cu. yds. concrete at \$8.50	85,000	28,333
15,840 lin. ft. of double track laying at \$1.00	15,840	5,280
22,200 sq. yds. granite block paving at \$3.00	66,600	22,200
Sewer connections	9,000	3,000
32,180 ft. wire cable at \$0.33	10,619	3,540
Total general street construction	\$304,396	\$101,465
Special Street Construction:		
Main vault at engine house and fixtures	\$ 8,000	\$ 2,667
Two end vaults with fixtures	5,000	1,667
Special street sheaves for summits of grades	1,500	500
Two grip switches	2,500	833
Two coach switches	1,000	333
One crossing	1,500	500
180 degs. of double tracked curve	9,000	3,000
Total special street construction	\$ 28,500	\$ 9,500
Rolling Stock:		
15 grip cars and grip at \$1,000	\$ 15,000	\$ 5,000
15 coaches at \$1,200	18,000	6,000
Total rolling stock	\$ 33,000	\$ 11,000
Grand total	448,396	149,465

With a cable speed of 3 miles per hr. for $19\frac{1}{2}$ hrs., and trains on 4 mins. headway, each train would make 110 miles per day; and 16 trains would make 1,650 train miles, or 3,300 car miles per day. The daily operating expense would be:

	Total per day.
Depreciation of cable.....	\$ 35.00
Repairs, track and buildings.....	6.00
Repairs, engines and line machinery.....	2.00
Repairs, grip and cars.....	7.00
House, track and cable expenses.....	6.00
Track service.....	8.00
Power and car house service.....	28.00
66 grip men and conductors at \$2.00.....	132.00
$5\frac{1}{2}$ tons (2,240 lbs.) coal at \$2.50.....	13.75
Water, oil and grease.....	3.25
Injury to persons and property.....	7.00
Licenses and taxes.....	7.00
General and miscellaneous expense.....	23.00
Total	\$275.00

It is clear that Mr. Fairchild's data on repairs of track, buildings, and engines are founded on too brief a term of years to be of any value, for they total only \$8 per day on an investment of \$82,000 for power plant and \$55,000 of rails alone. This expense of \$2,920 per year (\$8 per day) is not $2\frac{1}{2}\%$ on the buildings, power plant and rails—a manifest absurdity.

It will be noted that the \$35 daily depreciation of the cable is \$12,775 per year on a cable whose first cost is \$10,619. This is equivalent to a life of about 10 months. Mr. Fairchild states that the usual diameter of cables is $1\frac{1}{2}$ to $1\frac{3}{4}$ in. A $1\frac{1}{2}$ -in. rope has a tensile strength of 30 tons, and weighs $2\frac{1}{2}$ lbs. per ft. The average life of ropes of the best design, he says, has been $12\frac{1}{2}$ mos., with an average service of 83,400 miles. The general average for the country has been about 8 mos., with mileage ranging from 40,000 to 150,000.

Cost of Constructing and Operating Cable Rys., Kansas City.—Mr. D. Bontecou gives the following relative to the cost of construction and operation of a cable railway in Kansas City. The road was finished in 1889. It comprises 8.54 miles of double track line, which is equivalent to 17.08 miles of single track. It was operated as four distinct lines, with cables 14,200, 29,500 and 31,000 ft. long respectively, driven from one power house, and a fourth cable 18,900 ft. long driven from a second power house. The cable speeds were 7.8, 9.9, 9.9 and 10.3 miles per hr. No grades exceeded 10%. The rope was $1\frac{1}{2}$ -in. diam., carried on 12-in. pulleys, in a conduit 36 in. deep.

The cost of construction was as follows:

	Total.	Per mile of double track.
1. Real estate.....	\$ 116,736	\$ 13,654
2. Underground obstructions.....	20,286	2,377
3. Substructure	542,820	63,562
4. Track and line machinery.....	276,075	32,331
5. Paving	159,092	18,631
6. Buildings	184,392	21,593
7. Machinery	130,003	15,223
8. Equipment	202,926	23,760
9. Ropes and splicing tools.....	30,760	3,607
10. Patents	12,951	1,522
11. Engineering and miscellaneous exp.	83,017	9,719
12. Discount and interest.....	146,931	17,201
Total	\$1,905,989	\$223,190

The equipment comprised 99 combination cars, of which 61 were in constant service. The combination car contained the grip, seats for 40 people, and weighed 11,000 lbs. It ran on two 4-wheel trucks, with 22-in. wheels.

The machinery in the main power house consisted of three 200 hp. boilers and simple non-condensing engines. The machinery in the branch power house consisted of two 175 hp. boilers and engines. The total engine friction was 64 hp., the total resistance of all cables when no cars were on the line was 345 hp., and car resistance 166 hp. due to 61 loaded cars, or 2.72 hp. per car. About 30 hp. was used to supply electric light, etc. Total 641 hp., to which add, say 34 hp. for banking fires, etc., giving a grand total average of 575 hp. developed by two engines (one 38 x 48-in. and one 32 x 48-in. simple non-condensing) at the main power house. The coal (soft) contained 18% ash, and its cost was \$2 per ton (2,000 lbs.). The consumption was 11.86 lbs. per car mile (combination car), or 2.1 per ton-mile.

For the fiscal year of 1892, the operating expense was as follows:

	Total.
1. Car service and expense	\$ 73,315
2. Injuries to persons and property.....	5,087
3. Secret service.....	529
4. Repairs, cars.....	4,862
5. Car house service and expense.....	9,620
6. Maintenance, track and building.....	8,429
7. Motive power:	
Fuel	\$17,407
Water	1,157
Oil and grease.....	1,041
Engine house service.....	7,786
Repairs, machinery.....	268
Engine house expense.....	299
Ropes	29,381
Rope service.....	3,066
Repairs of grips.....	1,789
Total motive power.....	\$ 62,194
8. Taxes	4,596
9. General and miscellaneous.....	26,610
Grand total (13.8 cts. per car mile).....	\$195,242
Total car ("combination") mileage	1,415,366
Passengers carried.....	5,318,410
Average number cars run daily.....	61

The ropes lasted from 6 mos. on the short main line to 24 mos. on the branch line; the life of the four ropes averaging as follows. 20,000; 55,000; 68,000, and 130,000 miles respectively.

Since the line had been in operation only 4 years, the cost of car repairs, machinery repairs and track maintenance was obviously far below what a normal long period cost would be.

The operating cost was 13.8 cts. per car mile.

Cost of a Cable Railway in an Eastern City.—Mr. D. Bontecou gives the cost of a double track cable line in an Eastern city, as follows: The line was 3.05 miles long, almost straight, with 33,000 ft. of cable, and driven by a 300-hp. compound, condensing engine.

	Total.	Per mile of double track
1. Real estate.....	\$ 67,065	\$ 22,027
2. Underground obstructions.....	46,500	15,264
3. Substructure and track.....	222,386	73,010
4. Paving	83,000	26,946
5. Power house and vault.....	103,032	33,811
6. Machinery and plant	65,563	21,533
7. Equipment (88 cars).....	85,950	28,231
8. Rope	10,394	3,413
9. Patents	8,000	2,626
10. Interest during construction	22,136	7,254
11. Engineering, legal and miscellaneous	16,846	5,515
Total	\$730,872	\$289,630

Life of Cables and Cost of Operating Cable Railways, Chicago.—During the year 1898, the average life of 9 different cables, used on Chicago street cable railways, was 76,000 miles; but the life ranged from 44,000 miles to 120,000 miles per cable. The roads were level and with few curves, which accounts for the long life. Cables averaged 22,000 ft. long.

The cost of operation of cable and of electric lines in Chicago in 1898 was as follows:

	Cts. Per Car Mile.	
	Cable.	Electric.
Transportation	4.537	5.731
Maintenance of way and bldgs..	1.563	1.889
Power	1.092	1.065
General expenses	2.508	2.493
Maintenance equipment	1.115	1.811
Total, cts. per car mile...	10.815	12.929
Car miles	11,678,020	12,563,380

Use of trail cars on the cable accounts for lower transportation cost.

Labor Cost of Brickwork in Vaults of a Cable Railway.*—This work was done in 1892 in connection with the Third Avenue cable construction in New York City. The work was done by a sub-contractor, who furnished the masons only, all the other labor and

**Engineering-Contracting*, Sept. 5, 1906.

materials being furnished by the general contractor for the Third Avenue cable construction. The laborers assigned to the sub-contractor were directly under the charge of the masons, although the general contractor's foremen on adjacent work gave some attention to them.

The sub-contractor was paid at the rate of \$5 per 1,000 brick laid on all work except pulley vaults. For these he received \$8 per 1,000 brick laid for single vaults and \$10 for 1,000 brick laid for double vaults, these prices including cost of setting iron covers on the vaults. Twenty-one bricks were figured as making one cubic foot.

The masons were paid at the rate of 50 cts. per hour and they worked 8 hours per day. The foreman received 62½ cts. per hour and worked the same length of time as the masons. Laborers were paid \$1.55 per 10-hour day, the extra 2 hours being spent in getting the materials ready, screening sand, mixing mortar, etc. During July and August there was no regular foreman, the work being looked after by the sub-contractor. The latter, however, did not perform the usual duties of a foreman, as the work was spread over a stretch of two miles, with additional work at 65th street and Harlem. In the summaries, where the sub-contractor really acted as foreman on the different works, these works are charged foreman hours for the time actually spent upon them by the sub-contractor.

Several causes tended somewhat to increase the cost of the brick-laying, the main causes being as follows: An unnecessarily exacting inspection; a frequent scarcity of brick, or such as the inspector would allow to be used, this scarcity of brick being primarily due to a brickmakers' strike; the fluctuating quantities of work on hand, due mainly to the slow arrival of iron for the cable railway, and to interferences by the surface cars. Then, too, the cost of common labor was high for that time (1892), due partly to the fact that the work was located in the most crowded part of New York City. The extra labor was required for rehandling materials.

The force account was carefully kept and the amount done each day was carefully measured by one of the engineers in the employ of the general contractor. The masons' time in the force account is the actual time paid for by the sub-contractor and includes the time spent in moving from one piece of work to another, but does not include time spent in waiting for brick or lost during showers. The laborer time includes all labor connected with bricklaying after the brick were dumped by the brick companies and the cement (in barrels) delivered by the general contractor near the mixing box. There were, however, occasional transfers by the laborers of brick, cement and sand from one part of the work to another, this transfer being caused by a local scarcity of materials.

The bricks used were mostly "Up River" bricks, measuring 8 in. x 3½ in. x 2¼ in.; the sand was Cow Bay sand from Long Island, and the cement was White's English Portland. An average of 447 bricks were used per barrel of cement.

PULLEY VAULTS.

Pulley vaults were placed for every 35 ft. of track. These vaults were to permit the oiling and repairing of the pulleys of the cable road. The single pulley vaults were placed outside of the track, but the double pulley vaults were placed between tracks wherever the tracks were the standard distance (10 ft. $\frac{1}{2}$ in.), center to center. The single pulley vaults were constructed principally in the upper part of the Bowery, where a double vault could not be put in. The average height of both types of vaults was 4 $\frac{1}{2}$ ft. The single vaults each contained about 40.1 cu. ft. of brick work, or 841 bricks, and the double vaults each contained about 47.7 cu. ft. of brick work, or 1,002 bricks. About $\frac{1}{2}$ of the vaults had extra brick work for sewer connections. In building the vaults the cost of the mason work was necessarily large owing to cramped space in which to work, and owing to the fact that considerable time was lost in moving from one vault to another. There were generally three laborers to one mason. It will be remembered that the contract price for single pulley vaults was \$8 for the mason work and \$10 for the mason work for the double pulley vaults, the general contractor furnishing the materials. These prices include setting the iron cover. To do this last piece of work took one mason and three laborers one hour each, making the cost \$1 per cover. The average labor cost of the brick work was \$7.77 per cu. yd., divided up as follows. Masons, \$4.02; laborers, \$3.75.

During July to December, 96 days were worked, and 6,343 cu. ft. of brick work laid, at the following cost for labor:

	Per cu. ft.	Per M brick.
Mason	\$0.15	\$7.08
Laborers (mixers, helpers, tenders)	0.14	6.63
Total	\$0.29	\$13.71

The average number of bricks laid per mason per hour was 88, but during the best month the average was 96, and on the best day it was 106. The average number of brick per laborer hour was 25.

SPECIAL PULLEY VAULTS.

These vaults were constructed near the lower terminus of the line and were designed for the special iron work and pulleys required to operate the change from fast to slow cables. The average height of the vaults was 5 ft., their length was 10 ft., and all walls were 1 $\frac{1}{2}$ ft. thick.

The work was done in December, 10 days being required for its completion. In that time 1,070 cu. ft. of brick work were built, taking 22,485 brick. The wages of the masons amounted to \$112.31 and the laborers' cost was \$82.42. The average number of brick laid per mason hour was 122; the average number per laborer hour was 45.

The cost per cubic foot of brick and per M of brick was as follows:

	Per cu. ft.	Per M.
Masons	\$0.105	\$5.01
Laborers	0.077	3.67
Total	<u>\$0.182</u>	<u>\$8.68</u>

The labor cost per cubic yard of brick work was \$4.91.

THIRD CABLE VAULTS.

These vaults were for manholes to give access to the pulley carrying the third cable around the special iron work on Park Row. The vaults had an inside length of 4½ ft., and a width of 2½ ft. All of the walls were 1 ft. thick.

The work on these vaults was done in December, 7 days being required to complete the brick work. In that time 418 cu. ft. of brick work was built, requiring the placing of 8,776 bricks. The total cost of the masons was \$48.25, and the laborers cost \$42.65. The average number of brick laid per mason hour was 128; the average per laborer hour was 34.

The cost per cubic foot of brick work and per M brick was as follows:

	Per cu. ft.	Per M.
Masons	\$0.108	\$4.93
Laborers	0.102	4.89
Total	<u>\$0.205</u>	<u>\$9.82</u>

The labor cost of the brick work per cubic yard was \$5.53.

POSTOFFICE WHEEL VAULT.

This vault was constructed at the lower terminus of the line and was designed for the sheaves around which the cables pass. The work on the vault was done entirely under ground, the top being covered with 6-in. x 12-in. yellow pine timber to accommodate the street traffic. Kerosene lamps furnished the light to work by, extra labor being required to attend to the lamps. Two blowers, operated by two laborers, were used to keep the air fresh. However, excessively hot weather with insufficient ventilation had a serious effect upon the cost of the work. As there was no regular foreman in charge of the masons considerable loafing resulted, and the cost was consequently increased. In the construction of the arches of the vaults, the space between them and the roofing was so small that the masons were almost compelled to assume a prostrate position.

The height of the vault was 8 ft.; the inside dimensions were 19 ft. x 46 ft. The walls of the main vault were 1½ ft. thick. In addition, another vault 29 ft. long by 4½ ft. wide was built against the wall of the main vault. This vault had walls 1 ft. thick. The arches across the main vault were 19½ ft. long, were 1 ft. thick, and had a 3-ft. span and a 3-in. rise.

There were 2,812 cu. ft. of main walls built in 27 days (July and August), and the cost was:

	Per cu. ft.	Per M.
Mason	\$0.136	\$6.48
Laborer	0.180	8.66
Total	\$0.316	\$15.04

The masons averaged 86 bricks per hr., but the maximum was 146 bricks.

There were 746 cu. ft. of arches built in 7 days, and the cost was:

	Per cu. ft.	Per M.
Mason	\$0.109	\$ 5.18
Laborer	0.182	8.66
Total	\$0.291	\$13.84

The masons averaged 112 bricks per hr., but the maximum was 147. Laborers averaged 19 bricks per hr.

Cost of a Cable Railway for Freight Cars.—Mr. Edward Flad gives the following cost of a short inclined cable railway built in 1891 in St. Louis, for the purpose of taking freight cars (2 at a time) up a 6% grade to a brewery, 2,000 ft. distant from the main steam railway track. The rise is 96 ft. Switch tracks at both ends were of 63-lb. rails, but the cable railway track had 85-lb. rails. The rails rested on cast-iron yokes, 500 lbs. each, $3\frac{1}{2}$ ft. c. to c. The slot rail was a Z-rail, weighing 53 lbs. per yd. The conduit was made of 1. $3\frac{1}{2}$: 5 Portland cement concrete.

COST OF CONDUIT CABLE TRACK.
(1,873 lin. ft.)

<i>Grading and Track:</i>	Total.	Per lin. ft.
3,850 cu. yds. excav., at \$0.58.....	\$ 2,219	\$ 1.19
943 cu. yds. concrete mtl. and labor, at \$5.55..	5,231	2.80
51 tons T rails (85-lb.), at \$36.00.....	1,840	0.98
Freight on rails	179	0.09
32½ tons slot rail (53-lb.), at \$50.00.....	1,627	0.86
Bolts, shims, etc.....	497	0.27
Labor, tracklaying (except on concrete, which was \$896)	947	0.51
Castings for street crossing.....	1,100	0.59
273,174 lbs. cast yokes, at \$0.0155.....	4,234	2.26
53,338 lbs. manholes and covers, at \$0.0175....	933	0.50
16,276 lbs. sheaves and frames, at \$0.067.....	1,085	0.58
29,053 lbs. rack castings, at \$0.035.....	1,017	0.55
Extra castings, depression sheaves, etc.....	661	0.35
Total grading and track.....	\$21,570	\$11.52
<i>Paving for Conduit Track:</i>		
80 squares granite blocks, at \$18.75.....	\$ 1,500	
Sand	250	
Labor	408	
Total paving for conduit track.....	\$ 2,158	\$ 1.16

Repairs to Pavement:

300 squares macadam, at \$3.75.....	\$ 1,127	
50 squares gravel	212	
Total repairs to pavement.....	\$ 1,339	\$ 0.72
Cable	\$ 704	\$ 0.38
Total track, paving and cable.....	\$25,771	\$13.78
Grip Car	\$ 2,470	\$ 1.32
Holisting Engine (not incl. foundation).....	\$ 7,100	\$ 3.80
Total track, paving, equipment, etc.....	\$35,341	\$18.90

SWITCH TRACKS IN UPPER AND LOWER YARDS.
(7,700 lin. ft.)

Track:	Total.
85 tons T rails (63-lb.), at \$33.00.....	\$ 2,805
Freight on same.....	298
Track fastenings	816
Switches, frogs, etc.	2,518
Stringers, ties, etc.	2,139
Plank	746
Total track materials.. ..	\$ 9,323
Laying track, 7,700 ft.....	6,474
Total track in place.....	\$15,797
Paving.	
563½ squares macadam, at \$3.50	\$ 1,972
8.5 squares spalls	22
227 squares macadam, at \$3.75.....	851
15,000 granite blocks, at \$0.05.....	750
Granite pavers' wages.....	188
2,675 cu. yds. excav., at \$0.30	803
Total paving	\$ 4,586
Sewerage	\$ 909
Tools	\$ 830
Total track, paving, etc.....	\$22,120
Crossing gate, house, etc.....	397
Miscellaneous	481
Grand total, 7,700 lin. ft., at \$3.00.....	\$22,978

The foregoing does not include engineering.

The work was done by a contractor, who received 15% on the cost of all labor, which 15% is included.

The engine hoists at the rate of 5 ft. per sec. when the grip car, pushing two loaded freight cars, is ascending. The grip car is permanently fastened to the lower end of the cable. The cable track is straight, except for a curve at the lower end. Sixty to 80 freight cars handled daily.

The entire cost of this plant, cable road and side tracks, was \$58,319.

Cost of a Rack Railway, Pike's Peak.—Mr. Thomas F. Richardson gives the following relative to the Manitou and Pike's Peak Railway, built in 1890. It is a rack railway (Abt rack), 8.9 miles long,

with maximum grades of 25%, total rise 7,517 ft., 16° max. curve, total curvature 210° per mile. The gage is 4 ft. 8½ ins.; 40-lb. T-rails on hewn red spruce ties 7 x 8 ins. x 9 ft. The grading was done by contract, at 15 cts. for earth, 32 cts. for loose rock and 90 cts. for solid rock. These prices were much too low, and should have been 30% higher to yield a fair profit, although the grading was "paid for both ways"; i. e., if the contractor succeeded in moving a cubic yard of loose rock from cut to fill, he got 32 cts. for excavation and 32 cts. again in embankment.

The total cost of grading was \$150,900, or \$16,950 per mile, including log culverts and masonry abutments for 4 small bridges (20 to 30 ft. span). Laborers received \$2 per day.

The following was the weight of iron and steel per mile of track:

	Lbs. per mile.
1,584 rack bars, at 87.8 lbs.....	139,080
1,584 chairs, at 23.25 lbs.....	36,830
3,168 rack-rail bolts, at 1.97 lbs.....	6,240
3,168 wood screws, at 1.64 lbs.....	5,200
1,584 cover plates, at 1.89 lbs.....	2,990
3,168 spring washers, at 0.146 lbs.....	460
352 T rails, at 400 lbs.....	140,800
352 pairs angle bars (38-in.), at 32.75 lbs.....	11,630
2,112 bolts (¾ x 3-in.), at 0.48 lbs.....	1,010
12,672 spikes (5½-in.), at 0.55 lbs.....	6,970
Total iron and steel per mile.....	351,110
3,168 spruce cross-ties.	

The tracklaying cost \$4,275 per mile, including the cost of planing the ties (9 cts. each), engine service and everything except engineering. Had the material been more simply designed, this cost would have been much less.

There were 7 switches costing \$450 each complete with ties.

There were 4 locomotives, each weighing 26 tons when loaded with fuel and water. The round trip is made in 2 hrs. with a coal consumption of less than a ton.

The cars weigh 14,000 lbs., are 41 ft. long, seat 50 passengers. The train crew is one conductor and one brakeman; only one car in a train.

Cost of Conduit Electric Street Railways.*—Mr. A. N. Connett gives the following costs of a conduit electric street railway installed by him in 1895 at Washington, D. C. There were 21 miles of single track built. The following prices were paid for rails and splice bars:

	Per m.
Wheel rails	\$28.06
Slot rails	31.28
Guard rails for curves.....	46.25
Conductor rails	46.88
Joints complete, each \$1.20.....	

*Engineering-Contracting, July 14, 1909.

The cost per mile of single track was:

Rails of all kinds, at above prices.....	\$ 9,031.54
215.5 tons cast iron (yokes, incubator frames, covers, etc.), at \$28.19.....	6,054.75
Bolts, tie bars, clips, etc.....	1,518.82
Bonds for conductor rails.....	476.00
Tracklaying (all labor and hauling).....	2,864.27
Temporary track.....	162.04
2,507 cu. yds. all excavation (except cable ducts), at \$0.95.....	2,373.34
Sewer pipes and brick work for duct manholes.....	483.01
Cable ducts.....	1,032.65
Excavation for cable ducts.....	355.14
765 cu. yds. concrete for conduit, at \$7.09.....	5,422.02
514 cu. yds. concrete for paving base, etc., at \$4.62.....	2,258.74
6,375 sq. yds. paving (not including base).....	7,996.20
Special track work and curves.....	3,805.04
Extra bills of street contractor.....	1,163.20
Removal of sub-surface obstructions.....	3,240.09

Total per mile of single track.....\$48,338.47

The item of "cable ducts" covered the following totals for the 21 miles of track.

10,616 ft. of 12 way duct at.....	\$1.20
41 ft. of 8-way duct at.....	0.88
21,354 ft. of 4-way duct at.....	0.55
133 ft. of 2-way duct at.....	0.35

There were 9,207 cu. yds. of excavation for these ducts at 83 cts. per cu. yd.

The concrete for the conduit was 1 bbl. Portland cement, 12 cu. ft. sand and 22½ cu. ft. stone. The concrete for the paving base was 1 bbl. Cumberland cement, 10 cu. ft. sand and 20 cu. ft. stone.

The paving on the 21 miles of track was:

42,126 sq. yds. old stone block at.....	\$0.80
91,716 sq. yds. asphalt at.....	1.50

The temporary track is a very low item, the authorities having permitted a flat strap-rail to be laid on the pavement by means of flat tie bars with special seats at their extremities. The streets of Washington are exceptionally favorable for the construction of conduit roads, being wide and having little traffic.

For comparison study the following New York City figures by Mr. William C. Gottschall, engineer in charge of construction of the Second Avenue Railroad Co. of New York:

	Per mile of Single track.
Labor, at \$7.59 per lin. ft.....	\$39,720.90
Insulators, at \$1.40 each.....	696.53
Iron work, excluding yokes, at \$1.83 per lin. ft.....	6,684.25
224.7 tons cast-iron yokes, at \$25.30.....	5,678.68
Concrete.....	3,929.38
Hauling yokes and iron work.....	569.03

Total, without paving.....\$57,651.53

This does not include paving, special track work, feeder ducts, bonds, sewer connections nor temporary track. The item of labor, which is exceedingly high, includes digging trough, removing old track, repairing concrete, removing excess of earth, hauling all track material, and track laying.

Mr. Connett estimates the excess in cost of a conduit line over a trolley line as follows per mile of single track:

105 tons sheet rails, at \$31.80.....	\$ 3,287
40 tons conductor rails, at \$41.00.....	1,640
210 tons cast iron, at \$28.20.....	5,922
Bolts	600
Porcelain insulators	175
1,400 cu. yds. excess excavation, at \$1.00.....	1,400
1,200 cu. yds. excess concrete, at \$7.00.....	8,400
Sewer connections	3,000
Excess labor track laying.....	3,000
Special track work, excess.....	2,500
Total	\$28,924
Removing sub-surface obstructions, say.....	8,476
Total excess cost conduit.....	\$37,500
Deduct overhead trolley construction.....	2,500
Total difference in cost.....	\$35,000

The removing of sub-surface obstructions is merely a rough estimate.

The data on cable railways, on the preceding pages, may be consulted with advantage.

Cost of Electric Railway, Denver, Colo.—Mr. John P. Brooks gives the following as the cost of a single track line built (1899) in Denver, Colo.:

	Per mile.
94½ long tons of 60-lb. T-rails, at \$23.50.....	\$2,220.75
360 pairs of 60-lb. angles, at 40 cts. (too low).....	144.00
1,080 lbs. track bolts, at 2¼ cts.....	29.70
32 kegs railway spikes, at \$4.50.....	144.00
360 copper or plate bonds, at 25 cts.....	90.00
2,000 ft. B. M. plank for culverts.....	42.00
2,640 Texas ties, at 50 cts.....	1,320.00
180 ft. of curve and guard rails, at \$1.....	180.00
Hauling ties and rails.....	130.00
Laying 1 mile of track.....	550.00
1 mile No. 0 trolley wire.....	325.00
88 cedar poles in place and painted, at \$4.25.....	374.00
Overhead work incidentals, including hangers, insulators and ratchets (\$60), span wire (\$40), and labor (\$50).....	150.00
2,000 cu. yds. excavation for track trench, at 25 cts.....	500.00
	\$6,199.45
Add 5% for engineering.....	300.55
	\$6,500.00
Add 2 switches, at \$250.....	500.00
Total per mile.....	\$7,000.00

It is apparent that this line was not laid in a paved street. It will be noticed also that the price of rails, etc., was lower then than now. The cost of power plant and buildings is not included, but may be estimated at \$15,000 for a suburban line 5 miles long.

Where paving of streets must be done, use the data given in the section on Roads and Pavements.

Cost of Electric Railway, Third Rail Line.—Mr. Ernest Gosenbach gives the following relative to a first-class, third-rail suburban

line, 62½ miles long. Including switches and sidings, the number of miles of single track is actually 66. Of the 62½ miles, 6½ miles are laid in city streets.

	Total.	Per mile of line.
1. Excavation and embankment.....	\$ 96,000	\$ 1,536
2. Bridges, abutments and culverts.....	91,050	1,457
3. Two overhead railway crossings.....	64,000	1,024
4. Ties, 2,640 per mile, at 55 cts.....	96,250	1,540
5. Ballast, 2,200 cu. yds., per mile, at 80 cts..	116,000	1,856
6. Rails, 70-lb. per yd., at \$21 per ton delivered	225,000	3,600
7. Joints, spikes and bolts for 60-ft. rails....	29,500	472
8. Labor on track, 56 miles, at \$600.....	33,600	538
9. Labor in street track, 6½ miles, at \$1,800..	11,700	187
10. Farm and highway crossings.....	9,500	152
11. Wire fences, 24,000 rods, at 72 cts.....	17,500	280
12. Switches, special work, etc.....	21,000	336
13. Bonds, 24,000, at 61 cts. in place.....	14,650	234
14. Cross bonds and special bonding, at switches	2,000	32
15. Third rail, 70-lb. per yd., 56 miles, at \$36 ton	131,000	2,096
16. Insulators, spikes and bolts, at 62 cts. in place	12,000	288
17. Joint plates, bolts and labor laying rail...	9,800	157
18. Bonds, 15,000, at 72 cts. in place.....	10,950	175
19. Crossings and crossing cables.....	13,500	216
20. Trolley in streets, single-track span con- struction	24,000	384
21. Power station, 150 kw., at \$120 per kw....	180,000	2,880
22. Power station building, at \$11 per kw....	16,500	264
23. Transmission line, 55 miles, at \$1,400....	77,000	1,232
24. Sub-station, freight and depot buildings..	24,500	392
25. Sub-station, railway apparatus.....	65,000	1,040
26. Batteries	80,000	1,280
27. Telephone line	9,000	144
28. Block-signal system	35,000	560
29. Stations and platforms.....	4,250	64
30. Switch and platform-lighting circuit.....	4,000	64
31. General office building.....	8,000	128
32. Car shops, shop tools, etc.....	24,000	384
33. Car bodies and locomotive body.....	49,000	784
34. Trucks and air brakes.....	27,500	440
35. Electric car equipment	76,000	1,216
36. Lighting and power apparatus and sup- ply systems	70,000	1,120
37. Accidents, contingencies and insurance, 5%	89,000	1,424
38. Administration, superintendence, office ex- penses, engineering, etc., 6%	89,000	1,424
Total	\$1,962,750	\$31,429

This estimate does not include allowance for right of way, station ground and legal expense.

To reduce above costs per "mile of line" (62½ miles) to cost per "mile of track" (66 miles), deduct 5.3%.

Items 33, 34 and 35 must be added together to get the total cost of rolling stock, making \$2,440 per mile of line.

Cost of an Electric Street Railway, Chicago.—The following was the cost of a mile of double-track street railway in Chicago in 1895:

	Per mile dbl. tr.
283 tons (90-lb.) rails, at \$33.00.....	\$ 9,339
4,224 oak ties (5 x 8-in. x 7-ft.), at \$0.38.....	1,605
352 cast welded joints, at \$3.50.....	1,232
1,760 tie rods, at \$0.15.....	264
33,792 spikes ($\frac{1}{2}$ x $\frac{1}{2}$ x $4\frac{1}{2}$), at \$0.01.....	338
42,240 ft. wood filler.....	2,112
Labor at \$1 per lin. ft. of double track.....	5,280
Total, exclusive of pavement materials.....	\$20,170
10,560 sq. yds. cedar blocks, at \$0.30.....	3,168
146 cu. yds. sand, at \$1.25.....	183
435 cu. yds. broken stone, at \$1.50.....	653
10,560 sq. yds. gravel and dressing, at \$0.08....	845
10,560 sq. yds. 2-in. hemlock boards, at \$0.08..	845
Total	\$25,879

The above does not include the overhead system.

Cost of an Interurban Trolley Line.—Mr. Gilbert Hodges gives the following estimate of cost of an interurban electric trolley railway, based upon experience in New England in 1902:

	Per mile single track.
Roadbed, Land, Etc.:	
14,300 cu. yds. earthwork, at \$0.45.....	\$ 6,435.00
325 cu. yds. rock, at \$1.75.....	568.75
3 acres clearing and grubbing, at \$75.00..	225.00
3,000 cu. yds. gravel ballast, at \$0.50.....	1,500.00
640 rods wire fence, at \$1.00.....	640.00
Pipe culverts.....	50.00
Masonry for bridges and culverts.....	1,000.00
Wooden and steel bridges.....	1,300.00
Land for private right of way.....	1,000.00
Total roadbed, land, etc.....	\$12,718.75
Track:	
110 tons T-rails (70-lb.), at \$31.50.....	\$ 3,465.00
360 continuous rail joints, at \$1.54.....	554.40
2,640 chestnut ties (6 x 6 in. x 8 ft.), at \$0.54	1,425.60
5,870 lbs. spikes, at \$0.0225.....	132.07
720 bonds in place, at \$0.615.....	442.80
17 cross bonds, at \$0.50.....	8.50
Teaming material.....	270.00
Labor laying track.....	1,056.00
Total track	\$ 7,354.37
Overhead System:	
Poles (35 ft.), brackets, cross-arms, etc., in place.....	650.00
Trolley wire and overhead material in place.	1,100.00
Direct and alternating current feeders in place.....	1,750.00
Block signal and telephone systems.....	2,000.00
Total overhead system.....	\$ 5,500.00
Engineering and Superintendence.....	\$ 600.00
Grand total	\$26,173.12

This does not include buildings, power, equipment, interest during construction, etc.

Cost of Third Rail and Trolley Lines Compared.—'Electric Railways' (1907), by Sydney W Ashe, contains the following costs of third-rail and of trolley lines, as estimated by Thomas Conway, Jr.

The estimated cost of a third-rail line is as follows per mile of single track:

Item.	Per mile.
1. 2,640 ties, at \$0.75, delivered.....	\$ 1,980.00
2. 2,200 cu. yds. ballast, at \$0.80.....	1,760.00
3. 123.2 tons rails, at \$31.00.....	3,819.20
4. Joints, spikes and bolts.....	500.00
5. Labor on track.....	600.00
6. Farm and highway crossings.....	150.00
7. 640 rods wire fence, at \$0.75.....	467.20
8. Switches, special work, etc.....	300.00
9. Bonding.....	400.00
10. 61.1 tons third-rail, at \$36.00.....	2,199.60
11. Insulators, spikes and bolts, at \$0.62.....	109.12
12. Joint plates, bolts and labor laying rail.....	175.00
13. Power station	2,000.00
14. Power station building.....	275.00
15. 7,000 lbs. transmission line copper (500 pr. triple-strand), at \$0.2005.....	1,403.50
16. Pole brackets and insulators for transmission line....	450.00
17. Sub-station, freight and depot buildings.....	2,000.00
18. Sub-station railway apparatus.....	1,000.00
19. Telephone line	150.00
20. Block signal systems.....	500.00
21. Platforms	100.00
22. Switch and platform lighting circuit.....	70.00
23. General office building.....	125.00
24. Cars	5,500.00
25. Accidents, contingencies, etc., 5%.....	1,500.00
26. Administration, engineering, etc., 5%.....	1,500.00
Total	\$30,033.62

The estimate for a trolley line is essentially the same, except for the following items:

Item.	
4. Joints, spikes and bolts.....	\$1,000.00
9. Bonding, 35.2 bonds, at \$0.75 in place.....	264.00
10. Trolley wire (4/0), 3,382 lbs., at \$0.198.....	669.63
11. Brackets for trolley poles, 52, at \$1.50.....	78.00
12. Constructing overhead work.....	600.00
16. Trolley poles, 52, at \$7.50.....	390.00
Total	\$3,001.63

The total of the corresponding items (4, 9, 10, 11, 12 and 16) for third rail is \$3,559, an excess of only \$557 over the trolley line.

Mr. W. C. Gottschall gives the following estimates made by Mr. Maurice Hoopes of the difference in cost between a third rail and a trolley line:

THIRD RAIL LINE.

	Per mile
Extra length (15 ins.) of 500 ties, at \$0.075.....	\$ 37.50
500 insulators and fastenings, at \$0.50.....	250.00
62.86 tons (80-lb.) low carbon rail, at \$35 + \$2 frt.....	2,325.82
176 rail joints, at \$0.60.....	105.60
352 bonds (425,000 cir. mil.) in place, at \$1.00.....	352.00
300 ft. cable for crossings (1,000,000 cir. mil.), etc., at \$1.20	360.00
Laying rail	100.00
Total	\$3,410.92

TROLLEY LINE.

(Span construction, and assuming one line of poles chargeable to transmission line.)

22,774 lbs. copper (equiv. to 80-lb. rail), at \$0.17.....	\$3,871.58
50 chestnut poles (8-in. x 30-ft.), at \$5.00.....	250.00
Labor and materials for erecting.....	300.00
Total	\$4,421.58

Mr. W. B. Potter's estimate of the cost of a protected third rail is as follows:

	Per mile.
66 tons (75-lb.) third rail, at \$43.00.....	\$2,840.00
528 reconstructed granite insulators, etc., at \$0.40.....	211.00
352 bonds (No. 0000 G. E. 9" Form B), at \$0.38.....	134.00
21 71 tons channel iron (6-in., 31 1/4-lb.) guard, at \$45.00..	1,248.00
792 malleable iron supports for channel, at \$0.36.....	286.00
176 malleable iron fish plates and bolts for channel, at \$0.25	44.00
Labor of installation, including drilling rails and channel..	900.00
Total	\$5,662.00

Cost of Labor and Materials in Building Two Electric Railways.*—
Mr. Daniel J. Hauer gives the following:

It is difficult to keep accurate records of costs of all details, owing to the methods generally pursued in carrying on the construction of electric roads. The majority of lines are built within city limits, thus allowing only a short section of the street to be torn up at a time, and this necessitates one gang doing several different kinds of work in a single day. Consequently we find the "common labor" item covering a number of details; instead of the cost of each being listed by itself.

This reason still holds good and the writer regrets that this is the case in the data he will give in this article. Even though this is so, several valuable lessons can be learned from the records and they may serve to guide some engineers and contractors on future work.

The two examples given are descriptive of construction done in a Southern city, during a year when labor was being paid a comparatively high wage, out-of-door work being plentiful, and a job obtained easily. This, of course, added to the cost of the work.

**Engineering-Contracting*, February, 1906.

Example I.—Example I was done under a contractor on "force account," that is, at cost for labor plus a percentage. The work consisted of tearing up and partially destroying an old cable track and relaying the new electric roadbed. The old cable track rails and slot rails were taken out, and part of the concrete conduit and cast-iron yokes destroyed and filled in, then new ties and rails were laid and the street paved. The overhead work was not disturbed, so we present only the cost of track work. Unfortunately the cost of the various details was not kept separate, so we cannot give the cost of tearing up track, but can only show the total cost of common labor.

The working day was 10 hours and the following rates of wages were paid per day:

Superintendent	\$12.00
Paymaster and assistant superintendent.....	5.00
Material man	4.00
Assistant material man.....	2.00
Timekeeper	3.00
Foremen	4.50
Assistant foremen.....	2.50
Laborer	1.50
Water boy.....	1.00
Laborers in the iron gang.....	1.65
Watchmen	1.50
Bonders and blacksmith	3.00
Helpers	1.75
Block pavers	5.80
Rammers	3.96
Stonecutter	6.00
Cart and driver.....	2.75
2-horse team	5.00
4-horse team	10.00

The pavers, stonecutter and rammers were union men, hence the two first named worked but 8 hours and the rammers 9 hours.

About a mile and one-half of track was laid, the total costs of labor and materials being:

Labor	\$20,518.64
Paving	817.44
Paving materials	762.07
Gutters	341.28
Hauling	452.47
Permits from city.....	199.88
Engineering department	201.34
Rails, ties, angles, plates, bolts, etc....	12,532.97
Miscellaneous supplies	95.32
Total	\$35,921.39

The rail laid was of the girder type weighing 107 lbs. to the yard, or 168.14 gross tons per mile. The height of the rail was 9 ins., while the base was $5\frac{1}{2}$ ins.; the length of the rail section was 60 ft. The angle plates were 32 ins. long with 12 holes; the tie rods were $1\frac{1}{2}$ ins. by $\frac{1}{2}$ in., spaced every 6 ft. The two were spaced 2-ft. centers, while the spikes were $5\frac{1}{4}$ -in. by $9/16$ -in. The bonds were 10 ins. concealed.

The cost of the material was:

	Per lin. ft.
Rail, tie rods, spikes, plates, nut locks, bolts..	\$1.2894
Bonds0244
Tie2425
Handling from cars.....	.0030
	<hr/>
	\$1.6583

The cost of labor for tearing up the old track, excavating, laying and bonding for new and filling in ready for the pavers was \$2.581 per lin. ft. of track.

The cost per lineal foot of track for paving materials was \$0.10 and for labor was \$0.108, making a total cost of \$0.208.

The cost per lineal foot of track for the miscellaneous items, enumerated above, was \$0.17; this makes a total cost per lineal foot as follows:

Material	\$1.658
Labor (common)	2.581
Paving, including labor.....	.208
Miscellaneous170
	<hr/>
Total	\$4.617

The paving was granite block paving with large flag stone laid at street crossing for foot pavement. The majority of the blocks taken up from the old track were used, only about 10% of new blocks being substituted. The blocks were laid in sand, and cinders in wet places. The cost per square yard of paving was \$0.19, being 10 cts. for labor and 9 cts. for materials.

Example II.—This work was identically the same, replacing a cable roadbed with girder rails for electric track. The cable road was of similar construction, but the work was done by the railroad company's own forces, except the paving, which was let to contract, the company furnishing materials. The amount of work done was a little more than a mile of single track, yet in both cases the work was for double track in the heart of the city, where street traffic was heavy.

The prices paid labor in this case were as follows:

Superintendent	\$3.22
Foremen	2.50
Assistant foremen	2.25
Sub-foremen	2.00
Pavers	4.75
Rammers	3.50
Blacksmiths	1.90
Bonders	1.70
Surfacers and leaders.....	1.75
Laborers in iron gang.....	1.60
Laborers, including helpers, watchmen, etc.....	1.40
Water boys75
Cart and driver	2.50
One-horse team and driver.....	3.00
Two-horse team and driver.....	5.00
Team and driver for dragging rails.....	3.75
Four-horse team and driver.....	8.00
Team for hauling rails.....	9.00

The total cost for labor and all materials was as follows:

Labor	\$ 8,235.77
Paving	2,652.47
Paving materials	1,791.58
Gutters	106.21
Hauling	796.16
Permits from city	120.75
Engineering department	133.53
Rails, ties, angle plates, bolts, etc.	9,946.80
Miscellaneous supplies	105.79
	<hr/>
	\$23,889.06

The paving was done by contract, the railroad company furnishing all the materials, the contractor simply doing the labor of laying the Belgian blocks. There was 5,894.3 sq. yda. of paving, the contract price being 45 cts. per sq. yd. The cost of new materials per square yard was 31.4 cts., making a total cost per square yard of 76.4 cts. The paving in all cases ran 2 ft. outside of rail. This makes a cost per lineal foot of track for paving of 74 cts., being divided as follows: 44.2 cts. for the labor of laying and 29.8 cts. for materials. All the blocks were laid in sand, there being no other foundation.

The cost per lineal foot of track for track materials was the same as in Example I, namely \$1.658.

The miscellaneous cost, such as hauling, permits, gutters, etc., per lineal foot of track was 21 cts.

In this case the labor cost of the work can be divided under several heads, but still such division as should be made, cannot be given, as the records were not kept with such an idea. The labor costs per lineal foot of track were:

Superintendence	\$0.005
Foremen095
Laying and surfacing rails195
Labor of tearing up cable track, excavation, re-filling, spacing ties, etc.	1.030
Watchmen010
Water boys016
Blacksmith work012
Bonding009
	<hr/>
	\$1.372

This makes a total cost per lineal foot of single track as follows, and allows of comparison with similar cost in Example I:

Material	\$1.658
Labor (common)	1.372
Paving, including labor740
Miscellaneous210
	<hr/>
	\$3.980

It would seem from these figures that the company forces tore up the old cable road bed and laid the electric road for 63.7 cts. less per lineal foot of single track, or a difference of \$3,363.36 per mile. This, at a glance, seems like an extraordinary difference, and for that reason it would be well to analyze these records.

The first thing to be noted is the great difference in the wages of various men, the contractors paying the larger wage. The difference in the compensation of laborers was 10 cts. This was made up by the railroad company giving each man two car tickets daily, one for use in the morning and the other for evening use. The cost of these tickets was not included in the company's records. It was considered that there was no direct cost to the company, but such an idea is certainly erroneous. It would seem that at least 5 cts. should be charged for these two rides, making a total charge of about \$300. The other differences in wages are very hard to estimate, as the details of time on the two jobs could not be obtained.

The contractor has, in some cases, charged very high prices for some of his men, such as superintendent, foremen and some others. Some of these high rates were made necessary, as the men were paid full time, whether the weather permitted work or not, and as wages could only be charged the company when work was actually done, a higher rate than was paid was billed. Then, too, some of the wages paid by the company were very low, as foremen, blacksmith, bonders and a few others. The company failed to make a charge against their work for a pay master, material man and time-keeper. The roadmaster of the railroad and one or two other officials spent the greater part of their time in supervision of this work, yet no charge was made for this. All of these things would add materially to the cost.

Another matter, worthy of note, is that the contractors were only doing one stretch of work at a time, while the railroad company had as many as six jobs going on simultaneously. This reduced the cost of superintendence, blacksmithing and a few other items for the company, while the contractors were compelled to charge full time.

Another consideration was the class of work done. The contractor had no object but to give the best of work, the more it cost the greater his profits; but this was not so with the company's forces. Specifications were not lived up to, but rather ignored, and when difficulties were encountered, specifications were changed to suit the conditions. One foreman expressed the situation tersely when he said: "Anything goes with the company." Repairs to the work were necessary within a few months. As is always the case, cheap foremen do indifferent work, and foremen's salaries were small.

The percentage paid the contractor in Example I was 10%, hence his profit per lineal foot of track was 45.6 cts. Deducting this from his cost to the company we have \$4.161.

Taking into consideration all of these facts, and it is more than doubtful if the cost of the work by the company's forces was less than that of the contractor. It will also be noticed that there was no charges for plant, and also for clerical hire, although clerks from several departments did extra work on account of the reconstruction.

The writer believes that this is another lesson against such work being done by company's forces instead of by contract. He would not be understood as advocating having the work done by a con-

tract on the percentage basis, as both the costs of these examples are high, but it would be much more economical to let the work at contract. There would no doubt have been a number of responsible contracting firms only too glad to do these jobs for less money than they cost the railroad company. If the work was too irregular to let it upon a unit basis, or too uncertain to make it a lump sum job, it could have been contracted for, at cost plus a fixed sum. Then there would be no object for the contractor to "salt" the job, or even prolong the time or skimp the work. There is certainly much food for thought in the above figures.

The bonding of the rails on electric track is an important detail of the work. The labor necessary consists of reaming the hole out in order to make the contact good and in placing and tightening up the bond. The cost of labor and material per lineal foot of track for bonding has been given, but it may be of interest to consider the cost per joint or bond. The bond used, was a 10-in. concealed bond, that is a bond entirely covered up by the angle plate. The cost of the bonds, apiece, was 73.2 cts. In Example I, with bonders' wages at 30 cts. per hour, the cost of labor per bond was 41.7 cts., making a total cost of \$1.149. In Example II, with wages at 17 cts. per hour, the labor cost per bond was 24.5 cts. giving a total cost of 97.7 cts. This does not include the expense of putting on the angle plate and tightening up the bolts, as that is listed in the records of laying iron.

Both jobs were done in good summer weather. Traffic was maintained over one track while the other track was being rebuilt. No record was kept of the cost of laying these cross overs, consequently they were not charged against the work.

The management and organization of the forces was not up to the standard of our best contracting firms. A large per cent of the laborers were foreigners and they worked under sub-foremen or assistant foremen of their own nationality. This made it possible for the men to lose and waste time. Frequently instructions were misunderstood, so work was done wrong only to be changed. Some foremen were kept at work, not from their ability to handle men and obtain good results, but because they could furnish new laborers when they were needed. It was also possible for discharged men to go from the job at which they were laid off to another piece of work being done by the company and obtain employment. Any contractor knows the cost of such proceedings. They cannot be calculated but they show up on the wrong side of the ledger at the end of a season's work.

Cost of Street Railway Track with Rubble Concrete Base, Ft. Wayne, Ind.*—The track was single track in paved street, with sidings and turnouts, and the work consisted in excavating some 8 ft. wide and from 1 to 3 1/4 ft. deep, placing the concrete, laying track, and repaving. The construction is shown by Fig. 13. The costs as given by Mr. H. L. Weber, chief engineer, Ft. Wayne & Wabash Valley Traction Co., were as follows:

**Engineering-Contracting*, March 11, 1908.

There were 5,022 lin. ft. of single track made up as follows:

Main line, lin. ft.....	4,481
Sidings, lin. ft.....	476
Two left-hand turnouts, lin. ft.....	65
Total track, lin. ft.....	5,022

There were 3,970 sq. yds. of repaving made up as follows:

In gage of main track, sq. yds.....	3,399.1
On sidings, sq. yds.....	453.9
1-ft. strip outside of rails, sq. yds.....	1,117.0
Total paving, sq. yds.....	3,970.0

The excavation consisted of a trench some 8 ft. wide and from 1 to 3½ ft. deep. All excavated material was hauled away, teams costing 40 cts. per hour and common labor 16½ cts. per hour. The cost of excavation was as follows:

Excavating and hauling away.....	\$3,378.03
1 new road plow.....	25.00
Total cost	\$3,403.03

Fig. 13.—Street Railway Track.

This gives a cost for excavation of 67.7 cts. per lin. ft. of track.

The track was laid with old 5¼-in. rails, which were reversed end for end. The ties were spaced 30 ins. on centers. Altogether 4,957 ft. of track were laid, costing as follows:

Item.	Total.	Per lin. ft.
Labor	\$ 784.81	\$0.158
Ties	1,204.80	0.243
18 kegs spikes at \$5.....	90.00	0.018
8 kegs bolts at \$5.85.....	46.85	0.009
350 bonds at 60 cts.....	210.00	0.041
Totals	\$2,336.46	\$0.468

The concrete work comprised the making and laying of 1,260 cu. yds. of concrete at the following cost:

Item.	Total.	Per cu. yd.
Stone at \$1.25 per cu. yd.....	\$ 973.55	\$0.772
688 cu yds. gravel and sand at \$1	688.00	0.546
759 1/2 bbls. cement at \$2.....	1,519.00	1.205
Labor	527.68	0.418
Totals	\$3,708.23	\$2.941

This low cost of concrete per cubic yard was made possible by the use of cobble stones from the old cobble pavement in the concrete. It was estimated by the engineer that had broken stone concrete been used throughout the cost would have been \$5.50 per cu. yd., so that a saving of nearly one-half was effected by using the rubble concrete. The cost of the concrete per lineal foot of track was $\$3,708.23 \div 4,957 \text{ ft.} = 74.8 \text{ cts.}$

There were 3,970 sq. yds. of repaving which cost as follows:

Item.	Total.	Per sq. yd.
Gravel and sand	\$ 344.20	\$0.086
90 1/2 bbls. cement at \$2.	181.00	0.046
33,145 new brick at \$22.50 per M.	746.86	0.188
123,618 blocks at \$18.25 per M.....	2,256.86	0.568
Unloading and hauling brick	250.00	0.063
1 road roller.....	200.00	0.050
Labor	425.70	0.107
Totals	\$4,404.62	\$1.108

The cost of paving per lineal foot of track was \$8.8 cts. and the total cost of the work per lineal foot of track was.

	Per lin. ft.
Excavation	\$0.677
Track laying	0.468
Concrete	0.748
Paving	0.888
Total	\$2.781

This does not include the cost of the rails.

Comparative Cost of Street Railway Track Built with Steel and with Wood Ties *—A steel tie laid in concrete is cheaper than a wood tie laid in concrete or broken stone in street railway track construction, according to figures by Mr. C. H. Clark, Cleveland Electric Ry., Cleveland, O. Comparison is made between the standard construction with Carnegie steel ties on the Cleveland Electric Ry., and various standard forms of construction with wood ties.

The Carnegie tie is a steel I-beam 5 1/2 ins. deep with a top flange 4 1/2 ins. wide and a bottom flange 8 ins. wide. The ties are spaced 6 ft. apart on centers. A strip of 1:3:6 concrete about 2 ft. wide and 5 1/4 ins. thick is placed under each tie and the space between ties is filled with a 5 1/4-in. layer of concrete. The

* *Engineering-Contracting*, Nov. 7, 1906.

rods connecting the rails come over each tie. The actual cost of this construction per 100 ft. is given as follows:

	Per 100 ft.
16½ ties at \$2.50.....	\$ 41.66
17 cu. yds. concrete at \$5.....	85.00
Total	\$126.66
Total per foot of track.....	1.27

Using oak ties costing 80 cts. each and spaced 2 ft. on centers the cost of the several standard constructions per foot are given as follows:

No. 1.—Tamping with material taken out; no extra excavations:

	Per ft.
Tamping	\$0.04
Tie40
Total per ft.....	\$0.44

No. 2.—Seven inches broken stone under ties and concrete between the ties.

0.18 cu. yds. crushed stone, at \$1.50.....	\$0.27
1 cu. yd. concrete, at \$5.....	.50
Tamping crushed stone.....	.08
Extra excavation and removing the same.....	.07
Tie40
Total per ft.....	\$1.32

No. 3.—Seven inches broken stone under ties and broken stone between the ties:

0.28 cu. yd. of stone, at \$1.50.....	\$0.42
Tamping the same.....	.08
Extra excavation and removing the same.....	.08
Tie40
Total per ft.....	\$0.98

No. 4.—All concrete; 5 in. below and filled to the top of the tie:

0.218 cu. yd. of concrete, at \$5.....	\$1.19
Extra excavation and removing the same.....	.07
Tie40
Total per ft.....	\$1.56

No. 5.—Four inches concrete; 1 in. sand under tie and concrete between the ties:

0.208 cu. yd. concrete, at \$5.....	\$1.04
Extra excavation and removing the same.....	.07
Tie40
Total per ft.....	\$1.51

It will be seen that the steel tie construction is cheaper in first cost than any of the concrete constructions with wood ties. Referring to this comparison Mr. Clark says:

"This is on the assumption that white oak ties cost 80 cts. apiece. This price, of course, varies in different localities, and the difference in price can readily be applied for comparison. The life of the steel tie can readily be placed at 20 years, and the white oak at about 12 years.

Cost of Welding Rails by the Thermit Process.*—The following account of the methods and cost of welding a large number of rail joints by the thermit process has been obtained from Mr. M. J. French, Engineer Maintenance of Way of the Utica & Mohawk Valley Electric Railway. A part of this information appeared originally in a paper by Mr. French, read before the Street Railway Association of the State of New York, and the remainder, covering practically all of the matter on costs, was obtained from the author by the editors of *Engineering-Contracting*. Both the methods described and the costs given refer to work on the railway named above during 1905-6.

Thermit Process—The process of welding consists in pouring molten mild steel from a melting crucible into sand and flour molds placed around the rails at the joint. It is in detail as follows:

The rails having first been lined and surfaced, the joint is thoroughly cleaned with a sand blast or wire brush. Then the rails are heated by a gasoline or oil blow-torch to expel all moisture, and by heating the rails to a dull red better results are secured as the temperature of the molten steel is not reduced as much when coming into contact with the rails. After the joint is cleaned and heated a pair of molds made of an equal mixture of common clay and sand, or, preferably, of sand and 10 per cent of cheap rye flour, is clamped firmly to the rails. The molds are held by a wrought iron frame-work provided with handles to facilitate carrying. The molds being in place, the rail head is painted with a watery solution of red clay which the heated metal immediately dries up to a thin coating, the purpose of which is to prevent the molten slag or steel from uniting with or burning the rail head. After thoroughly luting all joints of the molds with clay of the consistency of putty, earth is packed around the outside of the molds. The molds and the rails are then given a final warming with the blow-torch, the flame being directed inside the molds to expel any remaining moisture. The crucible on its tripod is then set over the mold with its pouring hole directly over and about 2 ins. above the gate in the mold. After placing the tapping pin, iron disc, asbestos disc and refractory sand in the bottom of the crucible to act as a plug for the opening the thermit compound is poured in and in the center of the top is placed about one-third teaspoonful of ignition powder. A storm match starts the chemical process.

The thermit compound is composed of aluminum and iron oxide both in granular or flake form, the ignition powder is composed of aluminum and barium peroxide in much finer form. When the match is applied the barium peroxide ignites and releases its oxygen to the aluminum very quickly. The heat produced is so intense that it causes the iron oxide to release its oxygen, which in turn is seized by the aluminum and almost instantly the entire contents of the crucible are a boiling and seething mass. By this reaction the pure steel is liberated and settles immediately to the

**Engineering-Contracting*, Feb. 13, 1907.

bottom of the mold. The crucible is then tapped by striking the tapping pin with a special iron spade and the molten steel runs into the mold followed by the aluminum oxide and corundum slag. The chemical reaction described is completed in about 30 seconds, and in five minutes the molds can be removed.

Molds.—The molds are made by baking a mixture of sand and rye flour shaped on models. At first a mixture of one part clay and one part sand was used, but it resulted unsatisfactorily. The molds shrunk and checked badly in baking and required a great amount of careful luting to close the joints. Also the clay was baked like a brick by the great heat of the welded joint and was quite difficult to remove, adding somewhat to the expense. At the suggestion of an old foundryman trial was made of a mixture of clean, sharp sand, with 10 per cent of coarse rye flour; the mixture was moistened just enough to retain its form when pressed in the hand. This mixture proved satisfactory. It came away from the model without adhering, baked without shrinking and was hard enough to stand ordinary handling. By adding a teaspoonful of linseed oil to the mixture for a pair of molds it baked as hard as concrete—unnecessarily hard for ordinary purposes, but most desirable for special molds for broken or combination joints.

The molds are baked in a brick oven having a flat iron plate above the firebox to baffle the heat and above this two racks capable of holding twelve sets of molds. For baking a moderate heat, about the temperature required for making bread—has proved the most satisfactory; a higher temperature burned the rye flour and destroyed its cementing properties. One man receiving 15 cts. per hour makes and takes the molds and he can turn out 12 sets every five hours, or 24 sets per day. This gives a cost for labor of about 6¼ cts. per set. The molds actually cost about 10 cts. a set, counting in materials and lost time due to the full output of the oven not being required each day.

Crucibles.—The crucibles furnished by the Goldschmidt Thermit Co. cost \$7.25 each, but since using up the first six bought the railway company has made its own, buying magnesia tar from the Goldschmidt Thermit Co. at 2½ cts. per pound. The tar is mixed with 25 per cent of old crucible material finely powdered. These crucibles last on an average for about 30 joints. They are baked in the oven previously described with a higher temperature than that required for the molds. The cost of the crucibles is \$2.40 each, made up of the following items:

48 lbs. magnesia tin at 2½ cts.	\$1.20
12 lbs. old crucible powder, labor	0.15
6 hrs. labor at 15 cts., molding and baking	0.90
Fuel	0.15
Total	\$2.40

Cost of Welding.—The welding was done by a gang of 1 foreman and 3 laborers. This gang has never exceeded 20 welds per 10-hour day. The wages paid were: Foreman, \$2.50 per day, and laborers, \$1.50 per day. The welding portion consists of 16 lbs.

thermit and 2 lbs. iron punchings, or 15 lbs. thermit and 3 lbs. iron punchings, if a lower temperature seems desirable. The total cost of the welding portion, including igniting powder, tapping pin, and plugging materials for crucible, consisting of asbestos washer, iron disc and refractory sand, is \$4.25. The cost of welding 100 joints on T-rail 7 ins. high, 6 ins. base and 3 ins. head during 1906 was per joint as follows:

Cost of mold.....	\$0.10
Cost of crucible.....	0.10
Cost of casting materials.....	0.20
Foreman	0.25
Laborers	0.91
Thermit portion.....	4.25
Total	<u>\$5.81</u>

To this is to be added \$1.63, which is about the average cost of removing and replacing brick pavement at each joint for labor and materials, using old broken stone for concrete and cleaning old paving blocks. This addition brings the total up to \$7.44 per joint welded. The cost of welding 600 joints in 1905 on 9-in. tram head rail, including all labor, materials, tools and patterns incident to the work, experimenting with mold materials and cost of oven, was \$5.86. The cost of the original outfit for welding was:

1 automatic crucible.....	\$ 7.25
1 set mold models.....	12.00
1 set mold clamps.....	6.00
1 tapping spade.....	1.00
1 tripod for crucible.....	4.00
1 set mold boxes.....	2.50
Total	<u>\$32.75</u>

Precautions.—Certain precautions are necessary to get the best results by the thermit process, and some of these we quote from Mr. French's paper as follows:

"When we began welding this 7-in. rail we found that we could sledge off the welds and that the iron from the thermit compound had not united with the rail; also that the iron came up to the top of the rail head. We subsequently found that the mold models had become mixed, and we had used one of too small horizontal cross-section, and consequently the rail chilled the small volume of molten iron coming in contact with it. Upon enlarging the mold model so that the thermit portion furnished only enough iron to come up under the rail head, we obtained welds that resisted the most vigorous sledging that could be given with a 10-pound hammer. We were able to batter the weld out of shape, but could not separate it from the rail. This sledging test is now applied to all welds.

"We found when welding in the morning with rising temperature that tightly-closed joints often humped up when welded. This proved to be due to the latent compression in the rails that did not manifest itself until the rail ends became soft. These humped joints were ground down with an emery wheel grinder. We had

only a few of these joints when we realized the cause, and readily prevented such action by welding on cooler days or when the temperature was falling. We obtained the best results with joints open about $1/16$ to $1/32$ in., the expansion in welding closing tightly such an opening. We have made excellent combination welds between 80-lb. T-rail, 7-in. 70-lb. and 95-lb. T-rails and 9-in. girder rails. In making combination welds we found that it was essential to get a good body of metal between the upper side of the base of the deeper rail and the under side of the shallower section in order to secure the strongest type of weld.

"Thus far there has been no appreciable excess wear in the head of the rails at the welds and the heated portion seems to take the original temper, as it cools down slowly in about the same way as when coming from the rolls.

"A few portions of thermite, not over six, have been lost through failure of the workman to tap the crucible properly, or lack of luting around the joints of the molds. We have had but one explosion during our entire experience. That occurred after using the process 18 months, and was caused through carelessness in welding on a rainy day and in not thoroughly luting the molds near the top. The slag came in contact with the wet earth around the mold, but aside from the scare occasioned by the report and a slight burn on the foreman's arm from flying slag no harm was done, and the weld turned out to be a good one."

Cost of Electrically Welding 3,087 Rail Joints.*—Mr. P. Ney Wilson gives the following:

There are many miles of perfectly welded track in existence, and this fact seems sufficient to prove that the process is not a failure, for the successfully welded track, aside from the question of theoretical points in the process, furnishes abundant proof that with proper attention the weld is efficient and the nearest approach to the perfect joint that track engineers have yet seen.

The one important and serious drawback to the use of the weld was the inclination towards undue crystallization, caused by the sudden application of severe heat. This condition developed during the experimental stage and seems to have been obviated by the more scientific application of the process.

In the case of old track with more or less battered joints, prices should be obtained upon a step joint for raising the receiving rail sufficiently to surface the lowest spot on the dish with the abutting rail. To this figure should be added the cost of the bonds (loose and battered joints are usually accompanied with inefficient bonding); then add labor cost and incidental material and make a total. This total should be compared with the cost of welding, and, after considering the increased life due to welding, a decision based upon facts can be made.

To illustrate the point just made an example is chosen from work done at Camden, N. J., in the fall of 1905 on the lines of the South Jersey Division of the Public Service Corporation.

**Engineering-Contracting*, Mar. 20, 1907.

ORGANIZATION OF THE WORK.

The organization of the gang doing the work, as shown in the detailed statement, consisted of about 100 men, 75 of whom worked on the day shift and the balance of 25 on the night shift. It was found that it was not necessary to have more than 25 men working at night, as the day gang could keep ahead of the welding machine with very satisfactory results. The figures showing the average number of men in gang per day are based upon a ten-hour day at 15 cts. per hour, assuming that all the men received the same rate. This figure is shown in this way so that it can be applied in any locality where a higher or lower rate of wages is paid, for instance, the average number of men per day required on the entire operation was 97.6. This figure being arrived at, assuming that all of the men and teams worked at the same rate per hour, would effect, of course, the cost per joint labor for opening, closing, shimming and aligning, etc., in other localities, this latter cost being increased or decreased in proportion to the increase or decrease in the rate per hour, as the case may be.

The operation in Camden was handled by four foremen, two sub-foremen and on an average of three teams per day. The rate paid the foremen was 25 cts. per hour; rate for teams, 45 cts. per hour, and rate of men in the gang, 15 cts. per hour. It might be added that in the gang doing the work there was about 50 per cent of first-class track laborers at the 15-ct. rate. These men were experienced trackmen and the low cost per joint bears evidence of their capability.

The actual welding of the joints was done by the Lorain Steel Co. on contract at \$5.25 per joint. This price is governed, of course, by the number of joints covered by contract. They agree to pay to the railway company \$10 to \$12 per joint for every joint that breaks within one year from date of welding. The breakage for the first year was 1 per cent, the cost of cutting in new rails being covered by the rebate from the contractor. The track having been already subjected to all seasons of the year, we now assume that the breakage will be materially decreased until the rail is worn to a point where it should be relaid. Very little new material was used by the railway company, it consisting of iron shims, sand, oil for red lights, hacksaw blades and other inexpensive miscellaneous track material. It was not necessary to mix concrete for filling in holes for paving foundation, for in the above case the city was under contract with a paving company, who followed up the welding machines and replaced asphalt on Broadway and on Kaighn Ave. The paving on all other streets was placed by the railway company, using the men in the gang at the rate mentioned. The aligning, surfacing and shimming of the joints was done by six skilled trackmen under a foreman. These men were trained especially for joint repairs with the idea in view that too much care cannot be taken in bringing the joint to proper alignment and surface.

An important feature in the maintenance of way man is the obtaining of proper credit for old material, which has been returned to scrap or to stores, it being manifest that in case of welding rails that the bonds and the joints taken off should be credited to the operation.

COST OF WORK.

Haddonfield Pike.—The work on this street comprised the welding of the joints in both tracks of a double track line. Altogether 989 joints were welded in 7-in. girder rail of Pennsylvania Steel Co.'s section No. 238 and Cambria section No. 824. The rails were 60 ft. long. The pavement was Belgian blocks on sand. The work was started on Sept. 23, 1905, and was finished on Oct. 6, 1905, making 14 days' work. The average number of men in the gang per day, based upon a 10-hour day at 15 cts. per hour, inclusive of Sundays and rainy days, was 103.7. The price received for scrap fish plates was \$15.60 per gross ton and for copper bonds was 15½ cts. per lb. The cost of the work was as follows:

<i>Cost of Fitting Joints for Welding:</i>		Per joint.
103.7 men 14 days at \$1.50.....	\$2,177.55	\$2.201
Cost of material.....	140.85	0.142
Total	\$2,318.40	\$2.343
Credit for scrap.....	900.00	0.910
Cost after deducting credit.	\$1,418.40	\$1.433

We have, then, the cost of welding per joint as follows:

Cost of fitting joint for welding.....	\$1.433
Contract price for welding.....	5.25
Total	\$6.683

This figure gives a cost per mile as follows:

For 30-ft. lengths.....	\$2,352.76
For 60-ft. lengths.....	1,176.38

State Street.—The work on this street comprised the welding of 191 joints on 7-in. girder rail Cambria section No. 834. For 115 joints the rails were 80 ft. long, and for 76 joints they were 60 ft. long. The pavement was Belgian blocks on sand. For the scrapped fish plates the company received \$15.60 per gross ton, and for the copper bonds 15½ cts. per lb. The average number of men in the gang per day, based upon a 10-hour day and 15 cts. per hour, was 84.6. Work was started on Oct. 13, and finished on Oct. 16, 1896, and occupied three working days, making the average number of joints finished per day 63.6. The cost of the work was as follows:

<i>Cost of Fitting Joints for Welding:</i>		Per joint.
84.6 men 3 days at \$1.50.....	\$280.56	\$1.993
Cost of material.....	57.61	0.201
Total	\$458.17	\$2.294
Credit for scrap.....	174.26	0.912
Cost after deducting credit.	\$283.91	\$1.382

We have, then, the cost of welding per joint as follows:

Cost of fitting joint for welding.....	\$1.382
Contract price for welding.....	5.25
Total	\$6.632

These figures give a cost per mile as follows:

For 30-ft. lengths.....	\$2,334.46
For 60-ft. lengths.....	1,167.23

Broadway and Kaign Avenue.—This job comprised the welding of 715 joints on double-track line on Broadway, and of 64 joints on one-track on Kaign Ave., making a total of 779 joints. The rail in both cases was 7-in. girder Pennsylvania Steel Co., section No. 238. The pavement on Broadway was asphalt between rails, and part of shoulder and Belgian blocks along rails, on 6 ins. of concrete. On Kaign Ave. the pavement was bricks between rails and on shoulder and asphalt, both on 6 ins. of concrete. The rails in both cases were 30 ft. long. For the scrapped fish plates the company got \$15.60 per gross ton, and for the old copper rail bonds 15½ cts. per lb. The average number of men worked per day, based upon a 10-hour day at 15 cts. per hour, inclusive of Sundays and rainy days, was 99.7. The work was done in September and October, 1905, and lasted 13 days, so that the average number of joints finished per day was 60. The cost of the work was as follows:

<i>Cost of Fitting Joints for Welding:</i>		<i>Total.</i>	<i>Per joint.</i>
99.7 men 13 days at \$1.50.....	\$1,944.94		\$2.496
Cost of materials.....	239 78		0.307
Total	\$2,184.72		\$2.803
Credit for scrap.....	712 14		0.914
Cost after deducting credit.....	\$1,472.58		\$1.889

The work required replacing 1016.6 sq. yds. of asphalt at a total cost of \$2,589.65, or \$2 527 per sq. yd. As there were 779 joints the repairs amounted to 1.305 sq. yds. per joint, and cost \$3.298 per joint. We then have the total cost of welding per joint as follows:

Fitting joint for welding.....	\$1.889
Contract price for welding	5.25
Repairs to pavement.....	3.298
Total	\$10.437

These figures give a cost per mile as follows:

For 30-ft. lengths.....	\$8,131 97
For 60-ft. lengths.....	1,837.08

Moorestown Pike.—The work on this job comprised the welding of 1,128 joints on double track laid with 60-ft. 9-in. and 7-in. girder rail Pennsylvania Steel Co.'s sections No. 238 and No. 200. The pavement was Belgian blocks on sand. Scrap fish plates fetched \$15.60 per gross ton, and scrap bands 15½ cts. per lb. Work was started Oct. 16 and was finished Nov. 5, 1905, thus lasting 18 days. The average number of men worked per day, based on a 10-hour

day at 15 cts. per hour, inclusive of Sundays, and rainy days, was 93.6. The average number of joints welded per day was 62.6. The cost of the work was as follows:

<i>Cost of Fitting Joints for Welding:</i>		Total.	Per joint.
93.6 men 18 days at \$1.50.....	\$2,528.19		\$2.241
Cost of material.....	142.85		0.127
Total	\$2,671.04		\$2.368
Credit for scrap.....	1,030.19		0.913
Cost after deducting credit.....	\$1,640.85		\$1.455

We then have the total cost of welding per joint as follows:

Fitting joints for welding.....	\$1.455
Contract price for welding.....	5.25
Total	\$6.705

These figures give a cost per mile as follows:

For 30-ft. lengths.....	\$2,259.80
For 60-ft. lengths.....	1,179.90

Total Work.—Summarizing the above figures we have a record of which gives us the following:

Number of days worked.....	48
Number of joints welded.....	3,087
Number of joints welded per day.....	64.3
Average number men worked.....	97.6

<i>Cost of Work.</i>		Total.	Per joint.
Labor preparing joints.....	\$ 7,081.24		\$2.277
Materials preparing joints.....	581.09		0.188
Total	\$ 7,612.33		\$2.465
Credit for scrap.....	2,816.59		0.912
Cost after deducting credit.....	\$ 4,795.74		\$1.533
Cost replac. 1,016.6 sq. yds. asphalt	2,589.65		0.822
Contract price for welding	16,206.75		5.25
Totals	\$23,572.14		\$7.635

These figures give us a cost per mile as follows:

For 30-ft. rails	\$2,687.52
For 60-ft. rails.....	1,343.75

DISCUSSION OF RESULTS.

The first cost per joint, represents cost in labor and material to the railway company exclusive of the contract price for doing the welding. The average number of finished joints per day on the above operation was 64. It should be understood that this figure is arrived at by dividing the total number of joints by the total days, inclusive of Sundays and rainy days and loss of time, due to the moving of the machine from one street to the other. Under favorable conditions 80 joints per day of 24 hours can be opened, welded, repaved and left in finished condition.

In paved streets the question of expansion and contraction need be the cause of any worry on the part of the engineer, as,

there being little change in the temperature of the earth, there is correspondingly very slight expansion and contraction. Slip joints in closed streets are not satisfactory, and after practical experience are not being advocated, for the reason that it is practically impossible to calculate where the contraction strain will take place.

It was assumed that the rail welded would have to be relaid in four years, owing to battered joints, and from the fact that Broadway and Kalign Ave. was laid in concrete with asphalt paving and would cost for relaying \$5 per foot for paving alone, figures showed conclusively that a saving could be effected and the life of the rail increased from 75 to 100 per cent. On Haddonfield and Moors-town Pike the cost per joint per year for keeping them in a fair condition was 90 cts. This included opening and closing joint, placing new plates and shimming.

Taking into consideration the above figures and excessive cost of re-construction on Kalign Ave. and Broadway, it was evident that saving could be made by welding joints. One per cent of breakage was a small matter in comparison to the increasing bad condition of all of the joints. On Broadway and on Kalign Ave. with a total of 779 welded joints there were none broken. These two streets were paved with asphalt on concrete. The entire number of broken joints occurred on Haddonfield Pike and Moors-town Pike, where the track was laid on sand and paved roughly with rubblestone. To the condition of the paving was attributed the breakage, as in the winter months the snow and ice had an opportunity to get around the rail, reducing the temperature of the rail to such an extent that breakage followed.

The Lorain Steel Co. has recently successfully applied the process to T-rail track on Interurban lines, having welded a stretch of about six miles from Providence, R. I., to River Point. In this track they used expansion joints every 1,000 ft.

Cost of Erecting Trolley Poles.—A gang of 4 men digging holes and 6 men raising poles averaged 36 poles set per 10-hr. day, or 50 cts. per pole at this rate, and with wages at \$1.80 per day, a man digs 9 holes per day at a cost of 20 cts. per hole, and a man raises 6 poles per day at a cost of 30 cts. per pole.

In digging holes 24 ins. diam. and 5 ft. deep for telegraph poles, using a crowbar and "spoon" shovel, a man will dig only 3 holes a day in stiff clay, and 7 holes in average earth.

Cost of Reinforced Concrete Trolley and Transmission Line Poles.*—The Fort Wayne and Wabash Valley Traction Co. has made reinforced concrete trolley poles and transmission line poles, the cost of which was as follows in 1906.

The trolley poles are 32 ft. long, 8 ft. of which is below the ground level. The pole is 10 ins. square at the ground level and 6 ins. at the top, and is reinforced with 8 twisted steel rods, $\frac{3}{4}$ in. It contains $22\frac{1}{2}$ cu. ft. of 1 ÷ 3 ÷ 3 gravel concrete, and 122 lbs. of steel, weighs 3,300 lbs., and costs \$7.50 at the gravel pit. The transmission pole is 42 ft. long, 8 ft. being underground. It is 12

**Engineering-Contracting*, July 14, 1909.

1 in. square at the ground level, and 6 in. at the top, and is reinforced with 8 twisted steel bars ($\frac{1}{2}$ in.), 4 of which are 32 ft. long and 4 are 42 ft. long. It contains 29 cu. ft. concrete, 242 lbs. reinforcing bars and 21 lbs. of steps, weighs 4,400 lbs. and costs \$13.

First Cost and Cost of Operating a Trolley Line—"Street Railways," by C. B. Fairchild, contains the following estimate, made in 1892, of the cost of constructing, equipping and operating 3 miles of double track electric trolley line, with power station near the center of the line.

<i>Road Bed:</i>	Total.	Per mile of single track.
15,840 lin. ft. stone ballast (6 in. below ties and between ties), including excavation for same, at \$0.90	14,256	\$ 3,376
15,136 ties (5 x 7-in.) at \$0.45	6,811	1,135
1,056 double joint ties at \$0.75	792	132
31,680 ft. rails (78-lb.), including all other iron and steel at \$1.42	44,986	7,498
8 miles electrical construction, including copper return wire, at \$500.00	3,000	500
31,680 ft. track laying (labor, teaming and supt.) at \$0.30	9,504	1,584
28,158 sq. yds. granite pavement at \$3.00	84,474	14,079
Total road bed	\$163,823	\$27,304
<i>Special Street Construction:</i>		
2 cross-over switches at \$525.00	1,050	\$ 175
1 double track crossing	270	45
180 deg. double track curve	492	82
Total special street construction	\$ 1,812	\$ 302
<i>Overhead Street Construction:</i>		
270 iron pipe poles (6 x 5 x 4 in. x 28 ft.) and fittings at \$26.00	7,020	\$ 1,170
8 iron terminal and curve poles at \$50.00	400	67
278 poles set with concrete foundations at \$7.00	1,946	324
278 poles painted at \$1.00	278	46
10,224 lbs. (No. 0) trolley wire at \$0.16	1,534	256
2,200 lbs. (5/16, 7 strand) galvanized steel wire (50 ft. street) at \$0.055	121	20
15,600 lbs. feed wire (4 miles) at \$0.17	2,652	442
270 lbs. strain and anchor wire at \$0.04	11	2
3 miles line and insulating appliances, lighting arresters, etc., at \$300.00	900	150
3 miles labor stretching trolley and feed wire and attaching insulating appliances, at \$500.00	1,500	250
Total overhead construction	\$ 16,361	\$ 2,727
<i>Special Overhead Construction:</i>		
4 trolley switches at \$3.00	12	\$ 2
2 double track curves (90 deg.) at \$75.00	150	25
Guard wire and guard span half the line, with connections	250	42
Total special overhead construction	\$ 412	\$ 70

Power House and Plant:

Real estate.....	\$ 10,000	\$ 1,667
House, 100 x 175 ft.....	25,000	4,166
Steam plant, 1,050 hp. (35 hp. per car) (2 slow speed engines, boilers, etc.), at \$65.00.....	68,250	11,375
Electrical equipment (including generators, switch-board, etc.), 900 hp. (30 hp. per car) at \$35.00..	31,500	5,250
Total power house and plant.....	\$134,750	\$22,458

Rolling Stock and Equipment:

15 motor car bodies (16-ft.) at \$1,000.00.....	\$ 15,000	\$ 2,500
15 motor trucks at \$275.00.....	4,125	687
30 motors (20 hp.) and electrical appliances, at \$1,250.00	37,500	6,250
15 coaches (trailers) with trucks at \$1,200.00...	18,000	3,000
Total rolling stock.....	\$ 74,625	\$12,437

Car Barn and Repair Shop:

Real estate.....	\$ 2,500	\$ 416
Car house, fireproof.....	25,000	4,167
Plts. tracks and switches.....	4,000	667
Repair shop equipment.....	8,500	1,417
Total car barn and repair shop.....	\$ 40,000	\$ 6,667

Auxiliary Appliances:

1 electric snow plow and sweeper.....	\$ 5,000	\$ 833
Other snow appliances.....	1,000	167
1 wrecking wagon, tools and team.....	800	133
1 high wagon, tools and horse.....	600	100
1 express wagon and horse.....	350	58
1 heavy wagon and team.....	500	83
2 carts	100	17
Track tools, etc.....	300	50
Total auxiliary appliance.....	\$ 8,650	\$ 1,442
Grand total.....	456,429	75,906

I give the foregoing estimate principally as an illustration of an extravagantly expensive line, and one to which the estimator has applied the highest possible unit prices in nearly every item. It is by no means typical.

Mr. Fairchild gives the following estimate of cost of operating 16 trains (motor and trail car), running on 4 mins. headway, including an allowance for "depreciation." He figures the life of the destructible part of the plant at 20 years, and provides a sinking fund that at 3% compound interest will redeem the plant in 20 years. This amounts to \$13,870 per year, or \$38 per day, which shows that he figured this depreciation on a plant of about \$346,000.

	Per day.
Depreciation of plant and rolling stock.....	\$ 32.00
Repairs, engines, boilers, generators, etc.....	13.00
Repairs, cars (including motors).....	78.00
Repairs, track, overhead construction and bldgs.	47.00
Track cleaning, train and shop expense.....	14.00
Track service.....	8.00
Power and car house expenses.....	6.00
Car house service, inclusive of cleaning, inspection, etc.....	20.00
Engineers, fireman and dynamo tenders.....	25.00
66 motormen and conductors at \$2.00.....	132.00
12 tons (3,240 lbs.) coal at \$2.50.....	30.00
Water, oil and grease.....	10.00
Injury to persons and property.....	10.00
Legal, secret service and insurance.....	8.00
Licenses and taxes.....	7.00
General and miscellaneous expense.....	32.50
Total operating expense.....	\$478.50

Each of the 16 trains will make 110 miles per day, or 1,650 train miles, or 3,300 car miles per day for the line. Hence, dividing \$478.50 by 3,300 gives 14½ cts. per car mile.

The repairs to the power plant machinery, \$13 daily, amount to \$4,745 per year, or less than 5% on the first cost, which is altogether too low.

The repairs to cars, \$78 daily, amount to \$38,470 per year, or more than 38% of the first cost, which is ridiculously high.

The repairs to track, overhead construction and buildings, \$47 daily, amount to \$17,155 per year. Excluding the ballast and pavement, the track materials and labor cost about \$65,000, the overhead construction cost \$16,000; the buildings cost \$50,000; total \$131,000. Hence, the \$17,155 repairs is more than 13%; but iron poles, fireproof buildings and durable construction are provided throughout (except the ties). Hence, this item is inordinately high.

In brief, not a single item of repairs is correctly figured, and the most important items are wide of the truth. Errors of the kind made by Mr. Fairchild are best detected by expressing the annual costs of repairs as a percentage of the first cost.

Estimated First Cost and Cost of Operating a 4-Track Electric Railway.—“Electric Railway Economics” (1903), by W. C. Gottschall, contains the following estimate of the maximum cost of suburban electric railway.

	Per mile single track.
Rails (80-lb.), \$33 per ton deliv., and fastenings.....	\$ 5,100
Labor laying track.....	900
Track bonding.....	750
2,640 white oak ties (6 x 8 ins. x 8 ft.) at \$0.70.....	1,848
2,750 cu. yds. rock ballast at \$1.50.....	4,125
20,000 cu. yds. grading at \$0.30.....	6,000
Third rail.....	7,000
Copper and installation thereof.....	2,500
Bridges and culverts.....	12,000
Labor and incidentals.....	400
Power stations at \$100 per kw.; sub-stations at \$40 per kw.....	12,000
Rolling stock (5 min. headway).....	8,000
Real estate and right of way.....	20,000
Incidentals, including block-signals, telephones, fencing, etc.....	4,000
Total	\$90,623

RAILWAYS.

I

Mr. Gottschall gives an estimate of the probable cost of operating a 4-track interurban road, 24 miles long (New York & Port Chester), as follows:

96 miles of main single track.
 124 daily local trains each way, trains of 1 car.
 74 daily express trains each way, trains of 2 cars.
 4,500,000 car miles per annum.
 248 daily local trains both ways, 49 mins. each.
 148 daily express trains both ways, 31 mins. each.
 Hence:

$248 \times 49 \div 60 = 202.5$ car hours per day of local train service.

	Per car hr.
1 motorman at.....	\$0.30
1 conductor at.....	0.25
Total	\$0.55

$202.5 \text{ car hrs.} \times \$0.55 \times 365 \text{ days} = \$40,752$ per year.

In like manner for express trains:

$2 \times 148 \times 31 \div 60 = 152.8$ car hrs. per day.

	Per train hr.
1 motorman at.....	\$0.30
1 conductor at.....	0.25
Total	\$0.80

This is equivalent to \$0.40 per car hr. $152.8 \text{ car hrs.} \times \$0.40 \times 365 = \$22,309$ per year.

<i>Train Crews:</i>	Per year.
Train crews, local trains.....	\$40,752
Train crews, express trains.....	22,309
Total	\$63,061
Add $\frac{1}{2}$ for extra man.....	21,020
Grand total train crews.....	\$84,081

Station Crews:

22 stations using 5 men = 110 men.

$110 \text{ men} \times \$2.00 \times 365 \text{ days} = \$80,300$ yearly.

Maintenance of Equipment:

4,169,760 car miles plus allowance for extra occasions = 4,500,000 car miles.

$4,500,000 \text{ at } \$0.02 = \$90,000$ yearly.

<i>Maintenance of Roadway and Structures:</i>	Per mile per yr.
5% of \$5,092, first cost of rails and fastenings.....	\$ 254
6% of \$1,848, first cost of oak ties (at \$0.70 ea.)...	108
6% of \$2,700, first cost of rock ballast.....	135
Labor of section and line men:	
5 trackmen at \$1.80.....	\$ 9.00
2 linemen at \$2.50.....	5.00

Total per day for 12 miles.....	\$14.00
$\$14 \div 12 \times 312 \text{ days} =$	364
Repairs and renewals of fences.....	25

Total	\$ 886
Add for contingencies, etc.....	114

Grand total maintenance roadway.....	\$ 1,000
96 miles at \$1,000 yearly.....	96,000

Electric Power:

Weight of loaded motor car is estimated to be:

	Tons.
Car and trucks.	25
Electric equipment.	17
Total	42
Passengers	10
Total when loaded.	52

With 5,208 local car miles daily, at 52 tons per car, we have 270,816 ton miles. At 160 watt hours per ton mile (see Table XXVa) we have: $160 \times 270,816 = 43,330,560$ watt hours per day for local service. In similar manner we get 42,020,160 watt hours per day for express service; total 85,350,720 watt hours per 24 hr. day, or 85,351 kw hours.

Add:	Per cent.
Transmission loss from main station to 3d rail. . . .	18
Heating cars.	5
Lighting cars, etc.	2
Total to be added.	25

We have $85,351 + 21,338 = 106,689$ kw. hrs. per 24-hr. day, or a plant of 4,445 kw.

The cost per kw. hr. was estimated thus:

Power Station Labor:	Per day.
1 chief engineer	\$ 10.00
3 assistant engineers at \$5.00.	15.00
20 oilers at \$2.50.	75.00
3 switchboard men at \$3.50.	10.50
3 electric helpers at \$2.50.	7.50
6 cleaners at \$1.50.	9.00
6 condenser men at \$2.50	15.00
1 machinist and 2 helpers.	9.00
24 boiler men at \$2.50.	60.00
1 boiler cleaner and 2 helpers.	6.00
4 laborers at \$1.50.	6.00
Total labor per day.	\$ 223.00
Total labor per year.	\$ 81,395.00
Fuel.	
106,684 kw. at 2% lba. coal = 293,281 lba.; therefore, 146.69 tons coal at \$2.40.	\$ 352.06
Total labor and fuel per day.	\$ 575.06
Total labor and fuel per year.	209,897.00
Hence:	Per kw. hr.
$\$575 \div 106,684 =$	\$0.00538
Add for repairs, etc.	0.00112
Total	\$0.00650

This allowance of \$0.00112 per kw. for repairs of power station is equivalent to \$119.50 per day, or \$42,718 per year. Since a power station and sub-station would not cost more than \$149 per kw., the

total cost of power plant would be \$633,300 for a 4,443 kw. plant. Hence the \$42,718 repairs per year is about 7% of the first cost.

The allowance of 2 cts. per car mile for maintenance of equipment is far too low for large high speed electric cars (42-ton). He should have taken fully 10% of the first cost of each car, for annual repairs, and that divided by the annual car miles would have given the cost of repairs per car mile.

The allowance of 5% per year for renewals of rails is excessive. Mr. Gottschall errs seriously in this. He reasons as follows:

The life rails for main line service of steam railway trunk lines is 15 years; but such a service is equivalent to 20 years on a high speed electric line where heavy locomotives are not used. Hence, a life of 20 years, or 5% depreciation, for rails in an electric line is assumed. Mr. Gottschall fails to consider that when a rail is removed from a main line it has a scrap value of about half its first cost. This being so, it has depreciated only 2½% per year, instead of the 5% assumed by Mr. Gottschall.

On the other hand, the 6% depreciation that he assumes for white oak ties is too low. Such ties will not last more than about 10 years.

But then, on the other hand again, his assumed 5% annual depreciation of rock ballast is ridiculously high.

TABLE XXVa. WATT HOURS PER TON MILE.

Distance between stops, miles.	Watt hrs. per ton mile for schedule speed of					
	40 ml. per hr.	35 ml. per hr.	30 ml. per hr.	25 ml. per hr.	20 ml. per hr.	15 ml. per hr.
3	110	80	78	65	53	40
2½	121	90	83	74	54	40
2	142	99	86	80	60	41
1½	123	95	85	68	43
1	128	90	74	50
½	145	119	56
¼	120
Train friction in lbs. per ton....	35	30	27½	25	20	15

Note. 1. The breaking effort or retardation is taken at 150 lbs. per ton.

2. The stops are taken at 15 secs. each, except for the 15-mi. schedule, where 10 secs. are taken.

3. A schedule speed of 25 mi. will require actual speeds of 40 to 60 mi. per hr., etc.

4. The rate of acceleration for the long runs varies from 75 to 110 lbs. per ton, going as high as 210 lbs. per ton for the short runs.

5. The table applies only to single car trains. If more than one car is used, the train friction in lbs. per ton decreases, hence the electric energy required decreases.

6. The figures are for the electric energy required at the motors.

Cost of Power Plants for Electric Railways.—"Electric Railways" (1907), by Sydney W. Ashe, contains the following power plant costs estimated by Mr. H. G. Stott:

	—Per kw.—	
	Min.	Max.
1. Real estate	\$ 2.00	\$ 7.00
2. Excavation	0.75	1.25
3. Foundations, recipr. engines.....	2.00	3.00
4. Foundations, turbines	0.50	0.75
5. Iron and steel structure.....	8.00	10.00
6. Building	8.00	10.00
7. Floors, galleries and platforms....	1.50	3.50
8. Tunnels, intake and discharge.....	1.40	2.80
9. Ash-storage pocket, etc.....	0.70	1.50
10. Coal hoisting tower.....	1.20	3.00
11. Cranes	0.40	0.60
12. Coal and ash conveyors.....	2.00	2.75
13. Ash cars, locomotives and track....	0.15	0.30
14. Coal and ash chutes, etc.....	0.40	1.00
15. Water, meters, storage tanks and mains....	0.50	1.00
16. Stacks	1.25	2.00
17. Boilers	9.50	11.50
18. Boiler setting	1.25	1.75
19. Stokers	1.50	2.20
20. Economizers	1.30	2.25
21. Flues, dampers and regulators.....	0.60	0.90
22. Forced-draught blowers and air.....	1.25	1.65
23. Boiler, hand and other pumps.....	0.40	0.75
24. Feed water heaters, etc.....	0.20	0.35
25. Steam and water piping, traps, separators, high and low pressure.....	3.00	5.00
26. Pipe covering	0.60	1.00
27. Valves	0.60	1.00
28. Main engines, reciprocating.....	22.00	30.00
29. Exciter engines, reciprocating.....	0.40	0.70
30. Condensers, barometric or jet.....	1.00	2.50
31. Condensers, surface	6.00	7.50
32. Electric generators	16.00	22.00
33. Exciters	0.60	0.80
34. Steam turbine units complete.....	22.00	32.00
35. Rotaries, transformers, blowers, etc....	0.60	1.00
36. Switchboards, complete	3.00	3.90
37. Wiring for lights, motors, etc.....	0.20	0.30
38. Oiling system, complete.....	0.15	0.35
39. Compressed air system, etc.....	0.20	0.30
40. Painting, labor, etc.....	1.25	1.75
41. Extras	2.00	2.00
42. Engineering and inspection	4.00	6.00

Total, excluding items 4, 22, 31 and 34....\$102.00 \$148.00

Mr. W. C. Gottschall gives a similar estimate, as follows:

RECIPROCATING STEAM ENGINE POWER-STATION COSTS PER KILOWATT.

	—Per kw.—	
	Max.	Min.
1. Buildings	\$ 15.00	\$ 8.00
2. Foundations	3.50	1.50
3. Boilers and settings	17.00	9.00
4. Steam piping and covering	12.00	4.00
5. Engines	32.00	20.00
6. Generators	21.00	18.00
7. Pumps, etc.	1.00	1.00
8. Switchboards, etc.	4.00	1.50
9. Feed water heaters, etc.	2.00	1.00
10. Wiring conduits, etc.	6.00	3.00
11. Coal storage and conveyors	6.00	2.00
12. Smokestack and flues	2.00	1.00
13. Fuel economizers	4.50	2.50
14. Stokers	3.00	2.50
15. Ash conveyors	1.50	1.00
16. Incidentals	2.00	2.00
Total	\$132.50	\$78.00

A fair average is \$100 to \$110 per kw. The cost of sub-stations using rotary converters will range from \$38 to \$45 per kw. including the building. Land is not included in the above costs.

Cost of Power Plant and Equipment of an Electric Railway.—Mr W. A. Blanck gives the following estimated cost (in 1904) of the electrical equipment of a 60-mile, single-track, interurban trolley railway:

	Direct current.	Alternating current.
Power House:		
Building	\$ 10,000	\$ 10,000
Foundations	2,500	2,500
Boilers and settings	12,000	12,000
Steampipe and covering	7,500	7,500
Engines	22,000	22,000
Generators, two 400 kw.	18,000	23,000
Exciters	1,000	1,000
Step-up transformers, 800 kw.	8,000	7,500
Switchboard	3,500	3,000
Wiring	3,000	2,500
Feed water heater	800	800
Pumps	800	800
Coal storage	1,000	1,000
Smokestack and flues	2,000	2,000
Fuel economizers	3,000	3,000
Stokers	3,500	3,500
Incidentals	4,400	4,400
Total power house	\$103,000	\$106,500
Sub-station in Power House:		
Building extension	\$ 1,000	\$ 600
Synchronous converter, 300 kw.	4,800
Transformer, 300 kw.; 200 kw. alternating current	3,200	2,000
Switchboard	2,000	1,200
Wiring	1,000	500
Incidentals	600	200
Total sub-station	\$ 12,600	\$ 4,600

Transmission Line (48 Miles):

Poles (see Trolley Line below).

Copper	\$ 10,000	\$ 11,500
Insulators, pins and cross-arms.....	7,500	5,000
Erection	4,000	3,000
Incidentals	1,000	1,000

Total transmission line.....	\$ 22,500	\$ 20,500
------------------------------	-----------	-----------

Sub-stations Along Road:

Buildings, four	\$ 8,000	\$ 4,000
Synchronous converters, four.....	19,200	
Step-down transformers	12,800	8,000
Switchboards, four	8,000	5,200
Wiring	4,000	2,000
Incidentals	2,000	800

Total 4 sub-stations.....	\$ 54,000	\$ 20,000
---------------------------	-----------	-----------

Trolley Line and Feeders:

Poles, 3,500, at \$5.....	\$ 17,500	\$ 17,500
Poles distributed and set.....	4,000	4,000
Guys and anchors.....	2,000	2,000
Brackets with hangers.....	18,000	25,000
Copper, direct current:		
Feeder, 12 miles, 500,000 circ. mils.		
Feeder, 48 miles, No. 0000.		
Trolley, 120 miles, No. 000.....	95,000
Alternating current:		
Trolley, 60 miles, No. 00.....	21,500
Feed insulators	2,000
Erection	10,000	4,000
Incidentals ..	7,500	4,000

Total trolley line.....	\$156,000	\$ 78,000
-------------------------	-----------	-----------

Bonding of Rails:

Both rails bonded.....	\$ 30,000	
One rail bonded.....	\$ 15,000
Cross bonds	2,000	1,000

Total bonding of rails.....	\$ 32,000	\$ 16,000
-----------------------------	-----------	-----------

Rolling Stock:

10 vestibuled passenger cars, each with 4 motors, wt. 30 tons.....	\$ 75,000	\$ 85,000
2 express passenger cars, each with 4 motors, wt. 35 tons.....	18,000	20,500
2 baggage cars, each with 4 motors, wt. 30 tons	10,000	12,000
Snow plow and construction car.....	7,000	8,500

Total rolling stock.....	\$110,000	\$126,000
--------------------------	-----------	-----------

Summary:

Power house	\$103,000	\$106,500
Sub-station in power house.....	12,600	4,600
Transmission line	22,500	20,500
Sub-stations	54,000	20,000
Trolley line and feeders.....	156,000	78,000
Bonding of rails.....	32,000	16,000
Rolling stock	110,000	126,000

Grand total	\$470,100	\$371,600
Cost per mile (60 miles).....	\$ 3,168	\$ 6,193

The running schedule upon which the above is based is as follows. 5 local cars having 1-hr. headway; 1 express car, making round trip in 3 hrs.; 1 freight and baggage car, making trip between the two terminals in 8 hrs.

Cost of a Street Railway Power Plant and of its Operation.—Mr. R. W. Conant gives the following estimated cost of a street railway power plant and its cost of operation.

The plant has a capacity of 3,600 kw. There are three cross-compound condensing engines, three 1,200-kw. generators, and six water-tube boilers of 500-hp. each. The estimated cost of this plant in 1898 was:

Engines, condensers, heaters, separators and piping.....	\$ 91,800
Feed pumps and fuel economisers.....	18,000
Boilers and flue connections complete.....	61,000
Generators and switchboard complete.....	73,800
Building, chimney, engine and boiler foundations, coal handling apparatus, etc.....	120,000
Land	17,000
Engineering and sundries.....	5,000
Total	\$386,600

This is equivalent to \$107 per kw.

Mr. Conant estimates fixed charges at 11%, or \$42,526, distributed thus:

	Per cent.
Interest	6
Insurance and taxes.....	3
Depreciation	2
Total	11

The item of "depreciation" is badly underestimated, for it includes current repairs.

It is assumed that this station is operated with 3 shifts of men, 8 hrs. per shift, for 8,760 shift hours per year. The crew of one shift would be:

- 2 enginemen.
- 2 firemen.
- 1 oiler.
- 1 helper.
- 1 coal passer.

7 men at 27 cts. per hr. = \$1.89.

The plant is assumed to work with a load factor of 33½%, so that it actually averages 1,200 kw. for 8,760 hrs., or 10,500,000 kw. hours per annum.

Therefore, we have:

	Per kw. hour.
Fixed charges, \$42,526 ÷ 10,500,000.....	0.40 cts.
Wages, \$1.89 ÷ 1,200	0.16 cts.
Coal, 2.2 lbs., at \$3 ton.....	0.33 cts.
General expense, super., supplies and repairs.....	0.09 cts.

Total, including fixed charges..... 0.98 cts.

Mr. Conant states that the fuel cost would be practically doubled were non-condensing engines used, for he has assumed a steam consumption of only 14½ lbs. of steam per 1. hp., a transformer effi-

ciency of 90%, and a boiler efficiency of 9.4 lbs. of steam per lb. of coal.

He calls the above a "standard plant," an ideal capable of realization, which is exceedingly doubtful, however, as the actual records of some 28 street railway power stations show.

A summary of these 28 plants gives the following average:

Average capacity, 2,140 kw.

Average load factor, 30%.

Average number men per shift, 10.

Average number shifts, 2 of 12 hrs.

Average wage, 20 cts. per hr.

The average cost of generating power was:

	Per kw. hr.
Labor, 1.5 hrs., at 20 cts.....	0.30 cts.
Coal, 6 lbs., at \$2.10 per ton.....	0.58 cts.
General expense	0.16 cts.
Total, not including fixed charges.....	0.98 cts.

The "load factor" of 30% means that the average output of electricity during the entire year was 30% the capacity of the plant, hence it was 30% of 2,140 = 642 kw.

There was not a single one of these 28 plants that operated with as little fuel as Mr. Conant's "ideal plant," for the most efficient plant required 3 lbs. of coal per kw. hr.

The cost of labor per kw. hr. obviously varies greatly as the "load factor" varies. In one of these plants the load factor was as high as 57%, giving a very low unit cost (0.18 ct. per kw. hr.) for labor; while in another plant the load factor was only 11%, giving an extraordinarily high unit cost (1.1 ct. per kw. hr.) for labor.

As above pointed out, Mr. Conant's estimate of his so-called "fixed charges" on the plant, is entirely too low.

Cost of Operating Street Railways.—The most satisfactory records of this sort are to be found in the annual reports of the Massachusetts Railway Commission. The reports of other railway commissions are either less detailed or relate to street railways that are comparatively new.

Following is a brief summary showing the growth of street railways in Massachusetts.

Year.	Miles of single track.	Miles of operated by electricity.	Car miles, millions.	Cars.	Passengers, millions.
1887.....	470	20.6	2,633	125
1888.....	533	23.2	2,532	124
1889.....	574	51	24.3	2,942	143
1890.....	615	160	26.5	3,247	165
1891.....	672	229	27.7	3,494	176
1892.....	755	496	29.7	3,679	194
1893.....	874	711	34.5	4,040	214
1894.....	929	825	36.7	4,053	220
1895.....	1,038	1,016	43.7	4,426	260
1896.....	1,277	1,241	53.6	4,912	292
1902.....	2,444	100.3	7,144	465
1903.....	2,675	117.0	7,613	603

It will be noted that not till 1889 did electricity come into use, and not till 1898 had it practically displaced horse power.

Note that the mileage per car has hardly increased, nor the passengers per car mile.

According to the report for 1908, the assets of Massachusetts street railways were:

Construction	\$ 82,934,355
Equipment (rolling stock)	29,899,394
Land and buildings	39,663,442
Other permanent property	1,807,999
Cash	8,170,682
Miscellaneous assets	7,705,688
Total assets	\$170,164,909

The mileage was:

	Miles.
Railway line owned (1st track)	2,233.85
Railway line owned (2d track)	441.04
Total main track owned	2,674.89
Sidings, switches, etc., owned	166.70
Total track owned	2,841.59
Main track leased	577.10
Total main track operated	2,741.00

The equipment was as follows:

Box passenger cars	3,876
Open passenger cars	3,742
Total passenger cars	7,618
Other service cars	461
Snow plows	729
Other vehicles (wagons, etc.)	1,650
Electric motors on cars	18,649

We see from the above that the reported cost per mile of main single track operated was:

Construction	\$31,005
Equipment	11,103
Buildings and land	15,569
Total	\$57,677

It is evident that no reliance can be placed in the so-called cost of construction, for it really represents purchase price and not actual cost of construction.

The cost of equipment, however, appears to be reliable, for it indicates a cost of about \$4,000 per car.

There were 17,267 employees; 602,400,874 passengers were carried, and the gross earnings from operation were \$30,786,762. The number of car miles was 116,982,089, or 42,700 car miles per mile of track.

Table XXVI gives the operating expense, which I have calculated both in terms of the car mile and of the mile or single track operated.

The repairs of cars and electric car equipment (Items 9 and 10) amounted to \$2,429,253. Since the first cost of the equipment was \$29,899,394, it appears that repairs amounted to a little more than

8% of the first cost. However, sight should not be lost of the fact that half the equipment consisted of open cars, which are used only in the summer and at a time when the closed (box) cars are mostly idle. Therefore, the cost of repairs would be nearly double the 8% if all equipment were kept constantly busy, making the annual cost of repairs about 16% of the first cost of the active equipment.

These repairs doubtless include renewals.

Unfortunately the cost of rail renewals is not given as a separate item. The number of car miles per mile of track was less than half as many as on the average steam railway of America.

Item 14, Wages of Employees, evidently refers to conductors and motormen, but does not include employees in the power plant.

TABLE XXVI.—OPERATING EXPENSES, MASSACHUSETTS STREET RY., 1908.

		Per mi. single track.	Per car mile. cents.
<i>General Expense:</i>			
1. Salaries of officers.....	\$ 690,082	\$ 252	0.59
2. Office expenses and supplies.....	151,174	55	0.12
3. Legal expenses.....	421,611	154	0.36
4. Insurance	248,972	91	0.21
5. Other general expenses.....	407,804	148	0.35
Total general expense.....	\$ 1,919,143	\$ 700	1.64
<i>Maintenance of Way:</i>			
6. Repairs of roadbed and track.....	\$ 1,273,992	\$ 465	1.09
7. Repairs of electric line construction...	393,047	143	0.33
8. Repairs of buildings.....	184,747	68	0.16
Total maintenance of way.....	\$ 1,851,786	\$ 676	1.58
<i>Maintenance of Equipment:</i>			
9. Repairs of cars.....	\$ 1,157,680	\$ 423	0.99
10. Repairs of electric car equipment.....	1,371,573	464	1.09
11. Repairs of miscellaneous equipment..	75,124	27	0.06
12. Provender and stabling.....	56,021	20	0.05
Total maintenance of equipment....	\$ 2,660,398	\$ 934	2.19
<i>Transportation Expense:</i>			
13. Electric motive power.....	\$ 3,928,820	\$1,434	3.36
14. Wages of employees.....	7,948,277	2,901	6.80
15. Removing snow and ice.....	136,002	50	0.12
16. Damages for injuries.....	1,218,242	445	1.04
17. Tolls for trackage rights.....	97,023	35	0.08
18. Rents of buildings, etc.....	171,182	63	0.15
19. Other transportation expense.....	710,695	260	0.60
Total transportation expense.....	\$14,210,251	\$5,187	12.15
Grand total operating expense.....	20,541,573	7,427	17.56

Power to Operate Street Cars.—The following data relate to small motor cars.

The record of power consumed on an electric street railway, for the year 1895, is as follows:

Tons (2,240 lbs.) coal.....	19,172
Car-miles, motor car.....	5,677,581
Car-miles, trailer car.....	654,557
Car-miles, total	6,421,638
Car-miles, motor car per day.....	120
Coal per motor car-mile, lbs.....	7.6
Coal per car-mile, lbs.....	8.9
Passengers per car-mile.....	4.1
Ton-miles (2,000 lbs.), passengers at 140 lbs....	1,810,033
Ton-miles (2,000 lbs.), motor car at $8\frac{1}{2}$ tons....	36,900,873
Ton-miles (2,000 lbs.), trailer at $2\frac{1}{2}$ tons.....	1,645,140
Ton-miles (2,000 lbs.), total.....	40,356,046
Coal per ton mile, lbs.....	1.08
Engine hours	25,183
Elec. horsepower hours, total.....	15,305,254
Watt hours, per motor car-mile	2,032
Watt hours, per ton-mile.....	286
Watt hours, per pound of coal.....	266
Coal per electric horsepower, lbs.....	2.81
Watts per motor car-mile	16,562
Effort per ton-mile, foot-pounds.....	103,420
Average pull per ton.....	19.5
Schedule speed, miles per hour.....	7.37

The "average pull per ton" is calculated from the consumption of electricity, and not by dynamometer test.

Cost of Operating an Elevated Electric Railway.—"Electric Railway Economics" (1903), by W. C. Gottschall, contains the following actual cost of operating an elevated railway in a large city, operating electric cars at a scheduled speed of 16 miles per hour. The age of the cars is not given, hence no sound conclusions can be drawn from these data as to equipment maintenance:

	Per car mile.
1. Train crews, telegraphers, couplers and yard men.....	\$0.0237
2. Station men, agents, porters and laborers.....	0.0072
3. Maintenance and upkeep of cars, trucks and motive power	0.0125
4. Repairs of elevated structure and roadway.....	0.0065
5. Electric power	0.0123
6. Miscellaneous expenses, supplies, etc.....	0.0021
7. General expenses, salaries, etc.....	0.0084
Total	\$0.0727
8. Legal expenses and injuries.....	0.0053
9. Taxes	0.0065
Grand total	\$0.0845

The power was 2 kw. hra. per car-mile at the central station.

Power to Operate New York Elevated and Surface Cars.—In Manhattan elevated railways it is estimated that the electric power consumed per loaded car is as follows:

	Kw. per car.
Operating (current measured at the car).....	31.0
Heating (current measured at the car).....	4.8
Lighting (current measured at the car).....	1.5
Air pumps (current measured at the car).....	0.6
Total (current measured at the car).....	37.9
Line loss	7.8
Grand total at the switchboard.....	45.7

On the surface lines in Manhattan about 16 kw. per car in summer, and 25 kw. in winter, is required.

The power required at the switchboard to drive 224 elevated motor cars and 1,247 surface cars in Brooklyn was determined to be as follows:

	—Kw. per car.—	
	Surface car.	Elevated car.
Operation ..	15.95	36.85
Heating	8.30	8.35
Lighting	1.10	1.10
Total	25.35	46.30

Weight and Power of Motor Cars.—In the early days of electric railways small motor cars with bodies only 16 or 18 ft. long and with two 15-hp. motors were common. Such cars are still common in the smaller towns and cities, and are not entirely out of use even in the larger cities.

A large city car, 30 tons, with double trucks, equipped with four 40-hp. motors (160-hp. total), and seating 44 people, is now the standard for heavy city traffic.

Interurban cars vary considerably, but the following is fairly typical: Car 50 ft. long, seating 42 people, double trucks, weighs 34 tons, is equipped with four 75-hp. motors (300-hp. total), and maintains a schedule speed of 30 miles per hour.

Cost of Maintenance of Motor Cars.—Although considerable has been published on this subject, very little of value has thus far appeared. The reasons why the data are unsatisfactory are these: (1) The age of the cars is not given. Obviously new cars entail much less expense for repairs than old cars. (2) The first cost of the cars, the size of the motors and the size of the cars are not stated.

Pending further information, I recommend estimating the annual cost of repairs of motor cars (incl. motors) at 12% of the first cost.

If a large motor car costs \$7,500, the average annual maintenance over a long period of years (20) would then be \$900. If the car travels 30,000 miles per year, its maintenance will then be 3 cts. per car-mile.

If the life of a car is 25 years, and no sinking fund is established, renewals being paid for annually as they become necessary, then

4% of the first cost will be the average annual expenditure for renewals when distributed over a long term of years. Renewals (4%) being $\frac{1}{3}$ as much as current repairs (12%), we have 1 ct. per car-mile for renewals of a \$7,500 motor car, making a total of 4 cts. per car mile for repairs and renewals of a \$7,500 car, when distributed over a long term of years.

In 1902 the repairs and renewals of street cars in Massachusetts were 1.65 cts. per car-mile, and the first cost of the average car was \$3,000. If the cost had been \$7,500, as above assumed for large cars, we should have $2\frac{1}{2} \times 1.65 = 4.12$ cts. per car-mile for repairs and renewals. This makes an excellent check upon my estimate of 16% of the first cost for repairs and renewals of equipment. It was about 1883 that electric lines began to be built in Massachusetts, so that repairs and renewals of equipment 24 years later (1902) are a fair index of what may be expected in the future. Repairs and renewals of equipment per car-mile may rise still higher in Massachusetts, even with cars of the present cost, for the mileage of street railways doubled about every six years between 1890 and 1902.

The cost of maintenance of the power plant should be estimated in a manner analogous to the foregoing.

Railway Operating Expenses, Etc.—The annual reports of the Interstate Commerce Commission and the reports of the various state railway commissions contain valuable data on operating expenses.

The miles of trackway include all 1st, 2d, 3d and 4th tracks, and amounted to 243,322

The miles of roadbed (or "line") include only 1st track, and amounted to 222,340.

The miles of track include all tracks, main, branch, side and yard, and amounted to 317,083.

There are nearly 1.43 miles of track per mile of roadbed in America.

According to the report of the Interstate Commerce Commission for the year 1906, the following was operating expense, given for each item as a percentage of the total:

Maintenance of Way and Structures:	Per cent.
1. Repairs of roadway.....	10.726
2. Renewal of rails	1.432
3. Renewal of ties	2.509
4. Repairs and renewals of bridges and culverts	2.207
5. Repairs and renewals of fences and road crossings, signs and cattle guards.....	0.413
6. Repairs and renewals of bldgs. and fixtures	2.304
7. Repairs and renewals of docks and wharves	0.241
8. Repairs and renewals of telegraph.....	0.177
9. Stationery and printing.....	0.030
10. Other expenses.....	0.257
Total	20.296

Maintenance of Equipment:

11. Superintendence	0.561
12. Repairs and renewals of locomotives.....	8.080
13. Repairs and renewals of passenger cars.....	1.968
14. Repairs and renewals of freight cars.....	9.009
15. Repairs and renewals of work cars.....	0.268
16. Repairs and renewals of marine equipment..	0.233
17. Repairs and renewals of shop machinery and tools.....	0.668
18. Stationery and printing.....	0.047
19. Other expenses.....	9.583
Total	21.396

Conducting Transportation:

20. Superintendence	1.776
21. Engine and roundhouse men.....	9.275
22. Fuel for locomotives.....	11.119
23. Water supply for locomotives.....	0.850
24. Oil, tallow and waste for locomotives.....	0.385
25. Other supplies for locomotives.....	0.250
26. Train service.....	6.375
27. Train supplies and expenses.....	1.557
28. Switch, flag and watchmen.....	4.357
29. Telegraph expenses.....	1.751
30. Station service.....	6.307
31. Station supplies.....	0.611
32. Switching charges—balance.....	0.293
33. Car per diem and mileage—balance.....	1.231
34. Hire of equipment.....	0.201
35. Loss and damage.....	1.375
36. Injuries to persons.....	1.139
37. Clearing wrecks.....	0.700
38. Operating marine equipment.....	0.695
39. Advertising	0.422
40. Outside agencies.....	1.352
41. Commissions	0.017
42. Stock yards and elevators.....	0.055
43. Rents for tracks and yards.....	1.751
44. Rents of other buildings and other property	0.324
45. Stationery and printing.....	0.629
46. Other expenses.....	0.245
Total	54.482

General Expenses:

47. Salaries of general offices.....	0.826
48. Salaries of clerks and attendants.....	1.372
49. General office expenses and supplies.....	0.263
50. Insurance	0.481
51. Law expenses.....	0.452
52. Stationery and printing (g. o.).....	0.182
53. Other expenses.....	0.306

Total 3.876

Grand total (per cent)..... 100.000

Grand total..... \$1,533,404,385

The cost of operating expense, expressed in various units, was as follows:

Per train mile	\$1.3706
Per car mile (approximately).....	0.0833
Per mile of roadbed (line).....	6.894
Per mile of trackway.....	6.303
Per mile of track.....	4.836

By multiplying the percentage given for any item in the table of operating expense by any of the above unit costs of operation, the corresponding item unit cost is obtained.

Thus, Item 22, Fuel, is 11.119%. The total operating expense per train mile is \$1.37. Hence $\$1.37 \times 11.119\% = \0.1523 per train mile for fuel.

Thus, Item 2, Removals of Rails, is 1.432%. The total operating expense per mile of trackway is \$6,303. Hence $\$6,303 \times 1.432\% = \90.21 per mile of trackway for rail renewals.

In 1906, the total equipment of American railways was:

Locomotives:

Passenger	12,249
Freight	29,848
Switching	8,485
Unclassified	1,090

Total locomotives in service..... 51,672

Cars:

Passenger	42,262
Freight	1,837,914
Company service.....	78,736

Total cars in service.....1,958,912

It will be noted that there were 3.45 passenger cars per passenger locomotive, and 61.6 freight cars per freight locomotive.

The above does not include freight cars owned by private companies, on which the railways pay a mileage, the value of which is estimated to be \$72,000,000. Nor does it include cars owned by the Pullman Co., estimated at \$51,000,000. If the average freight car owned by private individuals is worth \$1,000, there would be about 72,000 of them. If the average Pullman is valued at \$10,000, there would be 5,000 of them. These numbers would increase the number of freight cars above given by about 4%, and would increase the number of passenger cars by about 12%.

The average weight of the locomotives (exclusive of tender) was 66 tons, of which 54 tons was on the drivers. The average tractive power was 24,300 lbs.

The classification of freight cars was as follows:

Box cars.....	243,118
Flat cars.....	146,908
Stock cars.....	64,202
Coal cars.....	486,717
Tank cars.....	5,324
Refrigerator cars.....	31,782
Other cars.....	55,584

Total1,833,635

The average capacity of these cars was 32 tons.

The following were the employees:

	Per day.	Total per year.
6,090 general officers.....	\$11.81	\$ 15,911,369
8,706 other officers.....	5.82	12,870,208
57,210 general office clerks.....	2.24	41,227,916
84,940 station agents.....	1.94	22,571,595
138,778 other station men.....	1.69	70,702,517
59,855 engine men.....	4.12	74,581,454
62,678 firemen	2.42	44,347,306
43,936 conductors	2.51	47,417,403
119,087 other trainmen.....	2.35	81,884,828
51,253 machinists	2.69	40,326,021
63,830 carpenters	2.38	40,961,083
199,940 other shopmen.....	1.92	111,524,564
40,463 section foremen.....	1.80	23,519,671
343,791 other trackmen.....	1.36	112,196,214
49,659 switch tenders, crossing tenders and watchmen	1.80	27,939,001
36,090 telegraph operators and dispatchers...	2.13	24,729,689
8,314 employees—acctg. floating equipment..	2.10	4,776,654
198,736 all other employees.....	1.83	103,414,175
1,521,355 Total		\$908,801,653

By multiplying the average daily wage by the total number of men in each class and dividing this product in the total annual payment, the average number of days worked can be ascertained. For all except "general officers" (240 days), and for "other trackmen" (270 days), the average is close to 315 days. The average employe received nearly \$600 per year.

In the case of trainmen, it must be remembered that the wage shown is not the true average daily income, for they are usually paid on an arbitrary basis, say 100 miles of run constituting a day's work.

The following is a summary of the service performed by the railways according to the 1906 report.

1. Passengers carried.....	797,946,116
2. Passenger miles.....	25,167,240,831
3. Passenger train miles.....	479,037,553
4. Passengers per train, average.....	49
5. Passenger's journey, miles.....	31.54
6. Freight, tons, excluding those received from con- necting roads	896,169,485
7. Freight, ton miles.....	215,877,551,241
8. Freight, ton miles per mile of roadbed.....	982,401
9. Freight, train miles.....	594,005,825
10. Freight, car miles.....	16,589,958,024
11. Freight, tons per train.....	344.4
12. Freight, average haul, regarding all railways as one system, miles.....	240.9
13. Total revenue passenger and freight train miles..	1,105,877,091

Item 13 would be the sum of items 3 and 9, were it not that there were also mixed trains (passenger and freight combined).

It will be noted that the number of passenger car miles is not given, but it can be closely approximated, as follows:

Dividing the 42,262 passenger cars by the 12,249 passenger locomotives, we find there were 3.45 passenger cars per passenger locomotive.

Hence multiplying the 479,037,553 passenger train miles by 3.45, we have 1,612,678,558 passenger car miles. This assumption implies that there would be as many passenger cars as locomotives in the shops, or otherwise idle. The Pullman sleeping cars are not included in the above, and as we have seen, they would add about 13% to the total number of passenger cars. On this assumption, the total number of passenger car miles would be about 1,806,200,000.

If we regard a locomotive and its tender as equivalent to two cars, multiplying the total train miles by 2 gives us the locomotive and tender car miles.

Hence we have:

Freight car miles.....	16,589,958,024
Passenger car miles.....	1,806,200,000
Total car miles.....	18,396,158,024
Locomotive and tender miles.....	2,211,754,182
Total car and engine miles	20,607,912,206

Since there were 243,322 miles of trackway, we have 20,607,912,206 ÷ 243,322 = 84,700 cars per year passing over each mile of trackway.

The importance of this deduction will be seen when we come to consider the wear of rails.

If we divide Item 13 (the total train miles), by the 243,322 miles of trackway, we have 4,540, which is the number of trains per year per mile of trackway. If we divide this 4,540 by 365 (the number of days in a year), we have a little more than 12, which is the number of trains per day both ways, or 6 trains per day each way on each trackway.

If we divide 16,589,958,024 (the number of freight car miles) by 594,005,825 (the number of freight train miles), we get nearly 28, which is the average number of freight cars per freight train.

We have seen that there were about 3.5 passenger cars per passenger train, plus nearly 0.5 Pullman car, or a total of 4 cars per passenger train.

Since about 45% of the trains were passenger trains and 55% freight, the average of both passenger and freight trains was about 17 cars.

Dividing 594,005,825 (the freight train miles) by 29,849 (the number of freight locomotives), we get nearly 20,000 miles per freight locomotive per year. This is not quite 55 miles per day.

Dividing 479,037,553 (the passenger train miles) by 12,249 (the number of passenger locomotives), we get nearly 40,000 miles per year, or not quite 110 miles per day. The average of both freight and passenger locomotives was about 25,500 miles per locomotive per year.

We have seen that there were 63 freight cars per freight locomotive, and that there were 28 cars per freight train. Hence

there were about $62 - 28 = 34$ freight cars not moving in trains, or about $34 \div 62 = 55\%$ of the car time was spent on sidings and in yards not attached to a locomotive.

If 45% of the time was spent moving with a freight locomotive, and if (as we have seen) a freight locomotive averages 55 miles per day, then $55 \times 45\%$ 24.75 miles were averaged per freight car per day. This may be arrived at with greater accuracy thus: 16,589,958,000 (freight car miles) divided by 1,958,912 (freight cars), gives nearly 8,460, which is the car miles per car per year, which is equivalent to 23.2 car miles per day. This checks very well with the approximate method first given. That method involved the assumption that time lost during shop repairs is the same for freight cars as for locomotives, which is not quite true, since about 5% of the total freight cars and 8% of the total locomotives are constantly in the shops. It also involved the assumption that there are not more locomotive crews than locomotives, which is not far from correct, since there were 59,855 enginemen to operate the 51,672 locomotives.

The average haul of a ton of freight was 241 miles, which would take nearly $10\frac{1}{2}$ days at 23.2 miles per day, including time spent in yards and sidings, loading and unloading; but, since 45% of the time (as we have seen) was spent on the road, $4\frac{1}{2}$ days of car time were spent on the road traveling and 6 days on the side tracks, etc.

The empty freight car mileage was 31.3% of the total freight car mileage.

Since the average number of tons per freight train was 344, and since there were 28 cars per freight train, the average carried by all cars (loaded and empty) was $344 \div 28 = 12.3$ tons nearly. Since 68.8% were loaded cars, the average loaded car carried $12.3 \div 68.8 = 17.9$ tons.

The income was:

Passenger revenue	\$ 510,032,583
Mail	47,271,453
Express	51,010,930
Other earnings, passenger service.....	11,314,237
Freight revenue	1,640,386,655
Other earnings, freight service.....	5,645,222
Other earnings from operation.....	59,741,198
Unclassified	262,889
<hr/>	
Total earnings from operation.....	\$2,326,765,167
Income from other sources.....	256,639,591
<hr/>	
Total earnings and income.....	\$2,582,404,758

Considering all the railways as one system, we have the following income account:

Earnings from operation.....	\$2,325,765,167
Clear income from investments.....	60,520,306
Gross earnings and income	\$2,386,285,473
Operating expense (incl. leased lines)....	1,537,448,702
Net earnings and income.....	\$ 848,836,771
Net interest on funded debt....	\$ 305,837,754
Interest on current liabilities.....	11,653,076
Taxes	74,786,615
Total fixed charges and taxes.....	\$ 391,776,445
Balance available for dividends.....	\$ 457,060,326
Net dividends	\$ 213,555,081
Balance available adjustments and im- provements	\$ 243,505,245

The revenue per train mile was:

All trains	\$2.075
Passenger trains	1.203
Freight trains	2.608

The average freight revenue was 0.748 ct. per ton mile. The average passenger revenue was 2.003 cts. per passenger mile. The operating revenue per mile of roadbed was \$10,460. The operating expenses were 66.08% of the operating income.

Average Life of Rails and Cost of Rail Renewals.—In determining the annual depreciation of rails subject to a given traffic I made the following analysis for the Railroad Commission of Washington.

The average cost rail renewals in the United States was \$75 per miles of trackway, or \$82 per mile of roadbed, or \$58 per mile of track, as deduced from the 1904 report of the Interstate Commerce Commission. The mile of trackway is the preferable unit, for it represents the mile of 1st, 2d, 3d and 4th track. Naturally, the wear on rails in side tracks is almost insignificant.

If the annual rail wear is \$75 per mile of trackway, it remains only to know the average cost of a mile of rails to arrive at the percentage of annual renewals. The weight of rails in the average track is about as many pounds per yard of rail as the weight in tons of the average locomotive.

In 1904 the average locomotive weight was 60 tons, and it is reasonable to suppose that the average weight of rail was not much in excess of 100 tons of rails per mile of track.

Now, if we can ascertain the average cost of a ton of rails delivered to the distributing point of the average railway, we shall be able to estimate the value of a mile of rails in the average track. To determine the "center of gravity" of the railway mileage of America, I assumed that the center of each state would represent, with sufficient accuracy, the "center of gravity" of the railway mileage of that state. To ascertain the "center of gravity" of the total mileage, co-ordinate axes were drawn and the distances from these axes to the center of each state were measured.

The abscissas and ordinates thus obtained were multiplied by their respective mileages of railway line. The sums of these prod-

ucts were divided by the total mileage of all lines, and the quotients were, of course, the abscissa and ordinate of the "center of gravity" of the entire railway mileage. This was found to be at a point not far north of St. Louis, Mo.

The practice of railways has been to charge $\frac{1}{2}$ ct. per ton mile for freight on rails, so that, in the year 1904, freight to the "center of gravity" of railway mileage could not have cost much to exceed \$3 per ton from Pittsburg, or \$1.50 from Chicago. The standard price of rails was \$28, so the total cost delivered was not to exceed \$31 per ton, and doubtless averaged less than \$30. As a matter of fact, rails cost the Northern Pacific and the Great Northern less than \$29.50 per ton delivered at St. Paul, at that time, so that we are safe in saying that the average cost of rails delivered to the average railway distributing point was not far from \$30 per ton. Hence enough new rails for an average mile of track (100 tons) cost about \$3,000. Since rail renewals actually cost \$75 per mile of trackway, we see that rail renewals cost $2\frac{1}{2}\%$ of the value of the rails in a mile of trackway. This is on the assumption that renewals of rails in side tracks was a comparatively insignificant item, which is practically so.

It must not be hastily assumed, however, that the life of the average rail is 40 years, for the fact is that it is less than half that. The \$75 per mile of trackway represents cost of new rails minus the scrap value, or relaying value, of the old rails. There is, at present, no means of knowing exactly what the practice of all railway companies is as to the credit given on their books for the rails that are replaced, but it is certain that an old rail is worth at least its scrap value at the mills less the freight to the mills, or about \$12 per ton. As a matter of fact, relaying rails are worth considerably more, and since many old main line rails are used for branch lines and particularly for side tracks, it is evident that the credit given to old rails will somewhat exceed \$12. From study of the accounting practice of several large railways, I concluded that \$15 per ton would be not far from the average credit. Hence the net cost of the new rails (after deducting the credit for the old rails replaced) would be \$15 per ton; and, since the annual rail renewals averaged \$75 per mile of trackway, there would be 5 tons of new rails laid per mile per annum. Hence in a track averaging 100 tons of rails per mile, this would mean 5% renewals every year, or a rail life of 20 years in the main and branch line tracks.

It is obvious that rail wear depends upon the density of traffic. In 1904, there were 829,500 tons of freight carried over each mile of roadbed, or 746,500 tons per mile of trackway. There were 4,379 trains that passed over each mile of trackway, or nearly 12 trains per day, of which 53% were freight, 44% passenger and 3% mixed trains. If we count an engine and its tender as equivalent to two cars, there were 78,546 cars passed over each mile of trackway during the year.

Wellington, in his "Economic Theory of Railway Location," has erred badly in his estimate of rail wear. He states that a rail

should carry 300,000 to 500,000 trains (of 500 tons each) before replacement. With 4,370 trains per year (the average of the U. S. in 1904), Wellington's rule would indicate a rail life of 100 years! This is at least five times the actual life of 20 years above shown. As I have shown on page 1462, about 22% of the average railway line is curved. Even assuming that the average curve is as sharp as 6°, which is, of course, far sharper than the average, and that a 6% curve increases the wear 100%, we see that the increased wear due to curves would be only 22% of 100% = 22% greater than if the entire mileage of track were tangent.

Part of Wellington's error arises from the assumption that a rail head can lose half its weight before renewal of the rail is necessary. As a matter of fact, Northern Pacific tests have shown that not more than one-quarter of the weight of the head is lost before renewals are made. On an 80-lb. rail, this would mean that when about 10% of its entire weight is lost by abrasion, the rail is unfit for further economic service, except in sidings and the like. Wellington was also misled by a belief that prevailed in the early 80's that a steel rail would last many times as long as an iron rail, a belief which was much too optimistic, as subsequent events have proved.

In selecting a proper unit in which to measure rail wear there has been much dispute. Wear may be measured in three ways: (1) in terms of the number of tons of gross weight that pass over the rail before it is worn out; (2) in terms of the number of trains; or (3) in terms of the number of cars. Wellington favored the train as the unit, for he says: "The locomotive alone causes by far the greater portion of this wear." He cites the opinion of Launhardt, a German writer, to the effect that the engine causes fully half the wear—a conclusion apparently based upon nothing but theory. He also cites some theoretical deductions of Mr O. Chanute. In brief, there was even then no real evidence to prove the contention that a locomotive causes as much wear as the rest of the train. At present, when wheel loads on the largest freight cars equal those on the average locomotive, the argument that a locomotive causes half the wear on a rail is manifestly absurd.

I am satisfied that rail wear is not a function of the number of gross tons carried, nor of the number of trains, but of the number of cars that pass over the rail. Nor do I think that the weight on the wheels is a very material factor in the cause of wear. Rail wear on tangents is due mainly to the grinding of particles of grit and steel between the wheel and the rail. The abrasion due to any grinding action is by no means proportionate to the pressure.

In sawing wood the weight of a cross-cut saw is sufficient to produce rapid abrasion of the wood, and nothing whatever is gained by bearing down on the saw. So, too, in cutting stone with grit or chilled shot, a comparatively light pressure is quite as effective in abrading the stone as is a heavy pressure: It should be remembered that it does not take a great weight applied to a grain of sand to produce a very large unit pressure between the grain of sand and the weight. It is this unit pressure that counts,

and it needs be only sufficient to cause slight penetration of the sand into the steel to result in abrasion. What is true of sand grains is true of all other particles between, or minute protuberances and irregularities upon the two abrading surfaces—the rail and the wheel.

As we have seen, the average rail in an American trackway has a life of about 20 years, when it carries 78,500 cars per year. Hence it carries $20 \times 78,500 = 1,570,000$ cars during its active life.

I think it is more than mere coincidence that the life of a steel rail in a street "tramway" in England has averaged 1,500,000 cars, as shown below. At any rate, it is evident that rail wear is far more nearly a function of the number of cars that pass over the rail than of any other unit yet suggested. It will probably be found, however, that the most exact unit in which to measure wear is the number of wheels that pass over a rail.

Curvature of Railways.—Since curvature affects the wear of rails, and thus affects the cost of track maintenance, it is of interest to know what per cent of the average railway track is curved. The following statistics, gathered in 1901, throw light on this matter.

Road.	Miles of roadbed.	Per cent curved.
Bur. Ced. R. & N.....	1,284	21
Chicago & Alton.....	900	12

Life of Rails on an English "Tramway."—Mr. T. Arnall gave the following data in a paper read in 1852 before the Tramway's Institute of Great Britain and Ireland.

At Birmingham, a steam motor car weighing 10 tons hauls a large car holding 50 passengers over girder rails weighing 98 lbs. per yd. After 8 years experience with a very heavy traffic, Mr Arnall concluded that such a rail will carry less than 750,000 steam cars before needing replacement. The life of the driving wheel tires is only 25,000 miles, due to steep grades (5%), and frequent use of sand. If we include the passenger car, we see that a rail carried 1,500,000 cars before it was worn out.

Average Cost of Maintenance of Equipment in America.—Individual railways are apt to show quite wide fluctuations from year to year in the cost of repairs and renewals of rolling stock. This is due largely to the financial condition of the company, and often to the desire to make an unusually good showing as to net earnings. On the other hand, the average of all roads in America would be the best possible criterion of maintenance costs were the actual first cost of the equipment known. Unfortunately it is not known, but we can estimate the approximate first cost with considerable accuracy, using the annual reports of the Interstate Commerce Commission and applying unit prices to various classes of equipment there described.

The report for 1906 shows that there were 51,672 locomotives of all kinds in the United States, and that the "repairs and renewals of locomotives" cost \$123,893,482, which is nearly \$2,400 per locomotive for the year. The average weight of each locomotive was 66 tons, not including the tender, with a weight of 54 tons on the drivers.

A 66-ton locomotive costs about \$12,000 new, hence the repairs and renewals for 1906 averaged 20% of the first cost.

While the rules of the Interstate Commerce Commission require the railways to charge to "renewals" the full cost of a new locomotive bought to replace an old one, the railways ignore this order, and properly charge to capital account the excess value of the new locomotive over the value of the old one. Hence the railway maintenance accounts show true repairs and renewals cost. It should be noted, however, that the amount charged to repairs and renewals of locomotives should be increased by nearly 10% of the 20%, distributed as follows:

	Per cent.
Superintendence of maintenance.....	2.9
Repairs and renewals of shop machinery.....	3.4
Stationery and printing.....	0.2
Other expenses	2.9
Total	9.4

This does not include repairs and renewals of shop buildings nor interest on the shop plant, nor "general expenses" of the entire railway systems, the latter being nearly 3.9% of the total operating expense.

However, if we add only 10% to the cost of "repairs and renewals" of each locomotive to cover the above named items of direct costs of shop machinery, repairs, etc., we have a total of \$2,640 per locomotive, or 22% of the first cost.

The 1904 report shows that locomotives averaged 60 tons weight and that "repairs and renewals of locomotives" averaged \$2,250 per locomotive. Since the average weight was nearly 10% less than for 1906, the "repairs and renewals" should be about 10% less, and such, in fact, is the case.

In 1906, the average locomotive traveled 27,400 revenue train miles. The actual locomotive mileage was somewhat in excess of this, but no data are given from which it can be computed.

Since the "repairs and renewals," which we shall now call 22% of the first cost of locomotives, includes true depreciation (renewals of entire locomotive), we must deduct depreciation to arrive at true repairs. There is no available record of exactly what this has averaged in America, but my study of the equipment records of the Great Northern, Northern Pacific and other lines, has led me to conclude that about 3.6% is the least percentage of locomotives that have been retired from service annually. This is equivalent to a life of 27.8 years. Due to the rapid increase in train loads in past years it is probable that from 1 to 5% of the locomotives have been retired annually. If we assume that 4% were retired in 1906, we have 22%—4% = 18% of the first cost spent for true repairs.

Of the 51,672 locomotives, 58% were freight, 16% switching, 24% passenger, and 2% unclassified.

In 1906 there were 1,833,635 freight cars whose rated capacity was 32 tons. The "repairs and renewals of freight cars" amounted to \$138,141,295, or nearly \$76 per car for the year. The first cost of a 32-ton car probably was about \$600, so that "repairs and renewals of freight cars" were about 12.7% of the first cost, to which should be added fully 10% (for reasons given) of this 12.7%, making a total of 14% as the annual cost of repairs and renewals. If 4% of the freight cars were "retired" in 1906, this would leave 10% as the cost of true repairs.

In 1906 there were 42,262 passenger cars, and their "repairs and renewals" totaled \$30,177,532, or \$715 per car. The probable average first cost of passenger cars is about \$6,000. Hence about 12% was spent for "repairs and renewals" to which should be added (for reasons above given) fully 10% of the 12%, making a total of about 13.2%.

If 4% were retired in 1906, the cost of true repairs was 9.2%. However, the percentage of passenger cars retired is somewhat less than freight cars. Hence true repairs of passenger cars doubtless were nearly 10% of the first cost.

Summing up we see that true repairs of equipment were about the following percentages of their first cost:

	Per cent.
Locomotives	18
Freight cars	10
Passenger cars	10

Repairs and renewals (= repairs and depreciation), were:

	Per cent.
Locomotives	22
Freight cars	14
Passenger cars	13.2

Cost of Maintenance of Equipment, N. P. Ry.—In making my appraisal of the equipment on the Northern Pacific Ry., as of June 30, 1906, I found the company's books showed the following original cost:

1,005 locomotives	\$12,977,823
478 passenger and accommodation cars..	2,865,197
127 sleeping and dining cars.....	1,588,792
196 baggage, express and postal cars....	685,750
37,584 freight cars.....	22,843,823
Floating equipment	497,102
Total	\$41,358,487

This gives an average unit cost of:

Locomotive	\$12,970
Passenger car	5,890
Sleeping car, etc.....	12,480
Baggage car	3,530
Freight car	610

The average first cost of each of three classes of equipment, and the average amount spent in repairs and renewals for the fiscal year 1906, were as follows:

	First cost.	Annual maintenance.	Per cent of first cost.
1,005 locomotives	\$12,970	\$2,540	19.5
800 passenger cars.....	6,340	630	10.0
37,584 freight cars.....	610	69	11.3

This annual maintenance (for the year 1906) includes repairs and renewals, but the "superintendence" and "other expenses" are not included, and they amounted to about 3.6% additional.

The locomotives average 78 tons weight, not including the weight of the tender; their average actual ages was 10.7 years, but their average "weighted age" was 8.6 years.

The average "weighted age" of the passenger cars was 11.1 years, and of the freight cars, 8.2 years.

At the prices now prevailing, this equipment would cost 10 to 15% more if bought new.

There were 137 switching engines in the above number and there were 229 passenger engines and 639 freight engines, and the 868 engines averaged 28,600 miles each, including all train and engine mileage, which was as follows

Passenger train miles.....	8,057,721
Locomotives helping passenger trains.....	393,974
Mixed train miles	849,035
Freight train miles	12,248,582
Locomotives helping freight trains.....	2,097,913
Non-revenue train miles.....	1,229,736
Total	24,876,961

Since the revenue train mileage was 21,155,338, the 868 locomotives each averaged 24,300 revenue train miles.

The car mileage was:

Passenger cars.....	59,298,843
Freight cars.....	415,358,345

The average was 6.66 passenger cars per passenger train, and 31.71 freight cars per freight train, of which 23.15 were loaded with 17.30 tons each = 400.47 tons load per train.

The total spent for maintenance of all equipment (excepting marine) was \$6,000,000, including superintendence and repairs of shop machinery. Since the first cost of all this equipment was \$41,000,000, we see that the average cost of repairs and renewals was nearly 15% for the year 1906.

Taking all locomotives and cars of all kinds (freight and passenger), the average first cost of each unit was \$1,000 and the average cost of repairs and renewals was \$150 or 15%. The value of this deduction will be apparent when we come to consider the percentage that should be allowed for annual repairs and renewals of electric motor cars. Many absurdly low estimates have been made as to the latter, based upon short experience with comparatively new equipment, and also without any regard as to the actual first cost of the equipment.

Life of Railway Cars and Locomotives, and Cost of Repairs, S. P. Ry.*—Mr. William Mahl, comptroller of the Union Pacific and Southern Pacific railways, gives some valuable data as to the life of equipment on the Southern Pacific Railway.

The following are averages for the period of six years, 1902 to 1907, the costs being the average cost per year:

Class.	Number Serviceable.	Expenditure on each per annum.	
		Repairs.	Vacated.
Locomotives	1,540	\$3,165	\$183
Passenger cars	1,504	759	104
Freight cars	42,983	70	17

In "repairs" are included the annual expenditure for repairs and renewals of each locomotive or car, other than the expenditure for equipment "vacated," or retired. In "vacated" is included the cost of equipment destroyed, condemned and dismantled, sold or changed to another class. In 1903 there was a fire which destroyed \$225,000 worth of passenger cars, bringing up the cost per car "vacated" to \$234 for that year, as against an average of \$82 per car per year for the other five years of the period. Hence the \$104 for passenger cars "vacated," as above given, is probably too high for a fair average.

From 1891 to 1907, a period of 17 years, the average number of freight cars "vacated" each year was 3.63% of the total number in service. Dividing 100 by this 3.63, we get 27½, which is, therefore, the average life in years of each freight car. These cars were nearly all wooden cars, of which the cost of a box car did not exceed \$450, excluding air brakes.

**Engineering-Contracting*, Oct. 23, 1907.

In the six-year period (1902 to 1907) the following was the record of equipment vacated:

	Loco- motives.	Cars.		
		Pas- senger.	Freight.	Road service.
Total number	284	299	11,797	468
Av. price per locomotive or car:				
Credited to replacement fund.	\$9,298	\$4,228	\$553	\$567
Charged to operating exp.....	5,742	3,140	372	380
Proceeds from sale or salvage.	3,558	1,087	180	188

Since there were 284 locomotives "vacated" in six years, the average was 49 per year out of the 1,540 in service, or 3.2%, which is equivalent to a life of 31 years. The life of passenger cars was practically the same.

There were nearly 2,000 freight cars "vacated" per year out of an average of 42,983 in service, or nearly 4.7%, which is equivalent to a life of but little more than 21 years. But in the years 1906 and 1907 6,338 cars were vacated, which is more than half of all vacated in the six-year period, indicating an unusual amount of replacement. This is also borne out by the fact that for the 17-year period the life of freight cars averaged 27½ years, as above stated.

Percentage of Engines Laid Off for Repairs.—In estimating the number of pits required in shops for repairing 1,000 locomotives on the St. Louis and San Francisco Ry., in 1907, various data were used, from which it was concluded that 70 pits would be needed. This is equivalent to 7% of the total number of locomotives constantly in the repair shops. However, many large railways count on 8% of the locomotives constantly in the shops. The records of the St. L. & S. F. showed that there had been 288 days worked each year by the men in the shops. Each engine was estimated to spend 20 days in the shop once a year, and to travel 30,000 miles between these periods of general repairs.

It is interesting to note how greatly the percentage of engines laid off for repairs has been reduced within recent years. On the Pennsylvania Ry., from 1851 to 1884, the average was nearly 18% constantly in the shops; for the years 1881 to 1884, the average was nearly 15%.

Percentage of Freight Cars Laid Off for Repairs.—This percentage is ascertainable with great accuracy, for it is shown in the weekly statistical bulletins issued by the American Railway Association of Car Efficiency (Chicago). The average number of freight cars constantly in the shops is about 5 to 5½% of the total cars in service.

Price of Locomotives.—Mr. Wm. P. Evans, of the Baldwin Locomotive Works, gives the following:

Type of Locomotive.	Weight, lbs.	1885.		Weight, lbs.	1905.	
		Price.	Price per lb. cts.		Price.	Price per lb. cts.
American	80,857	\$6,695	8.28	102,200	\$9,410	9.20
Atlantic				187,200	15,750	8.30
Mogul	72,800	6,662	9.12			
Pacific				227,000	15,830	7.00
Ten wheeler	85,000	7,588	8.92	156,000	15,690	8.80
Consolidation	92,400	7,888	8.54	192,460	14,500	7.50

The price per pound is figured from the total weight of the engine with three gages of water in the boiler, but excluding the tender.

Cost of Shop Machinery.—Mr. M. K. Barnum gives the following as the actual cost of shop machinery and tools for several different locomotive repair shops:

Shop.	Number of tools.	Locomotives.		Area of shops sq. ft.	Cost of tools.
		At one time.	During year.		
A	96	9	120	47,300	\$76,800
B	254	16	216	62,000	188,100
C	226	22	300	131,300	147,400
D	237	22	300	96,000	174,300
E	282	50	600	238,000	264,800

He estimates the average useful life of shop machinery and tools at 20 years.

Cost of Stopping Trains.*—Mr. J. A. Peabody states that an official of a Western railway gave him the following as the cost of stopping trains, determined by experiment.

An 8-car passenger train, weighing 530 tons, including engine and tender half loaded, from and to a speed of 50 miles per hr., costs as follows per stop:

	Lbs.
Coal to stop train (air pump).....	30
Coal to accelerate train (estimated).....	275
Total coal	305
	Per stop.
305 lbs. coal, at \$2.15 per ton.....	\$0.33
Brake shoe wear and tire wear (from laboratory tests)	0.03
Wear of brake and draft riggings, etc. (estimated)	0.06
Total	\$0.42

The lost time in starting and stopping on a straight, level track, averaged 145 secs., or nearly 2½ mins. This is the actual loss from the time that would have been required to make the trip had no stop been made.

The corresponding items of cost of starting and stopping a 2,000-ton freight train (80 cars) from and to a speed of 35 miles per hr. were:

	Lbs.
Coal to stop train (air pump).....	50
Coal to accelerate train.	500
Total coal	550
	Per stop.
550 lbs. coal, at \$2.15.....	\$0.56
Brake shoe wear.....	0.16
Other items, as classified above.....	0.29
Total	\$1.00

*Engineering-Contracting, Feb., 1906, p. 49.

Cost of Handling Locomotives at Terminals.—Mr. Charles H. Frye gives the following costs of handling locomotives at terminals in 1903.

On the St. Louis & San Francisco line, the average cost per engine per time handled was \$1.57 for wages of hostlers and assistants, fire cleaners and asphalt men, front end cleaners, wipers, boiler washers and assistants, sand dryers, laborers or sweepers and callers.

On the Norfolk and Western, the cost was \$1.30 for repairs plus \$0.52 for watching and hostling, total \$1.82 per engine per time.

On the Mobile and Ohio, 4,832 locomotives were handled at the following labor cost per time:

Hostlers	\$0.30
Boiler washers	0.10
Callers (calling engine crew)	0.03
Sand dryers	0.03
Coalers ..	0.80
Wipers ..	1.13
Machinists	0.36
Boiler makers ..	0.12
Truck repairers	0.13
Total	\$3.05

On the Texas & Pacific the cost of despatching, in and out of terminals, was 2 cts. per engine mile, or \$2.21 per engine per time.

On the Wabash Ry., 17,060 engines were despatched by 636 men, during 1903, at the following labor cost per engine per time:

Repairs	\$0.98
Handling	0.84
Total	\$1.82

On the Lake Shore & Michigan Southern, the cost of all round-house expenses, including skilled mechanics on ordinary running repairs, was:

Skilled mechanics	\$1.87
Other labor ..	1.73
Total ..	\$3.60

On the Seaboard Line, 7,615 engines were despatched at the following unit cost:

Repairs ..	\$1.13
Supplies, labor	0.03
Roundhouse men ..	0.64
Total	\$1.80

An Eastern road having 476 locomotives, handled at 31 round-houses by 231 men, gives the following unit cost for 13,388 despatches monthly:

Handling	\$0.79
Running repairs	2.83
Coal	8.32
Supplies	0.43
Water and water station	0.70
Total	\$13.07

A Western line with 312 locomotives on 1,300 miles of line gives the following unit cost:

General	\$0.70
Washout	0.27
Wiping	0.10
Cinders	0.13
Hoisting	0.89
Coaling	0.35
<hr/>	
Total	\$2.35
Roundhouse repairs (heavy engines).....	2.50
<hr/>	
Total	\$4.85

These engines average 125 miles per engine handled.

CHAPTER XII.

BRIDGES.

The Weight of Steel Bridges.—To compute the approximate cost of a steel bridge, it is first essential to estimate its weight. Formulas for estimating weights are given in this section, together with many examples of weights of bridges actually built, both for highway and for electric and steam railway purposes.

The following formulas, taken from Johnson's "Modern Framed Structures," give the weight of steel in trusses and floor-beams of highway and railway bridges.

For a highway bridge with a roadway 16 ft. wide, designed to carry 100 lbs. live load per sq. ft., use the following formula.

$$W = 12 L + 150.$$

W = weight in lbs. per linear foot of bridge.

L = span in feet.

For bridges of less or greater width of roadway than 16 ft., subtract or add 15 lbs. per lin. ft. for each 2 ft. change in width.

For railroad bridges designed according to Cooper's E-50 loading, the weight of steel per lin. ft. of bridge is as follows:

For deck plate girders,

$$W = 12 L + 150.$$

For through plate girders with beams and stringers,

$$W = 12 L + 500.$$

For truss bridges,

$$W = 7 L + 650.$$

The Weights of Steel Bridges for Highway, Railway and Electric Railway, Spans of 10-ft. to 300-ft.*.—In this issue we shall confine ourselves to the weights of standard bridges on the Northern Pacific Ry. and on the Santa Fe Ry., followed by Tyrrell's formulas for calculating the weights of bridges of moderate size.

Weights of Standard Bridges, A. T. & S. F. Ry.—These single track bridges are designed to carry a moving load of two 139-ton consolidation engines, followed by a train weighing 3,200 lbs. per lin. ft., according to specifications drawn in 1902.

**Engineering-Contracting*, Sept. 23, 1903.

Estimated Weights of Single Track Through Pin Truss Bridges;
Atchison, Topeka & Santa Fe Ry.

Span c. to c. of pins. Ft.	Weight per span. Lbs.	Class.
100.....	193,700 ¹	D
103.....	183,300	D
110.....	195,300	D

*Weights given for girders Class C and D are for round ended girders.

Classes *A* and *C* are designed in the most economic manner and are used wherever possible. Class *B* is for spans of the least depth consistent with good service. Class *D* is for spans with shallow floors.

Classes *B* and *D* are used only where it is less expensive to use these shallow bridges than to change the grade line. The tabular weight is the calculated weight plus 2½%. If the shipped weight is in excess of the tabular weight the excess is not paid for.

Weights of Standard Bridges, N. P. Ry.—In 1899 standard plans were made for Northern Pacific Ry. bridges. The assumed live load was two 146-ton locomotives, followed by 4,000 lbs. per lin. ft. of track. The following table gives the approximate weights of single track steel bridges, the weights being given closely enough for purposes of preliminary cost estimates.

I Beam:	
Span in ft.	Weight in Lbs.
20.....	10,000
30.....	20,000
Deck Plate Girders:	
25.....	13,000
35.....	20,000
40.....	25,000
50.....	37,000
60.....	50,000
70.....	63,000-73,000
80.....	96,000
90.....	112,000
100.....	132,000
Through Plate Girders:	
40.....	40,000
50.....	53,000

Formulas for Weights of Railway Bridges.—Mr. H. G. Tyrrell gives the following formulas: All weights (W) are per lineal foot of single track bridge for steel only; units 10,000 to 12,000 lbs. per sq. in. The live loads assumed are two engines weighing 100 tons each, and 4,000 lbs. per lin. ft. of track.

Deck plate girder bridge.....	$W = 100 + 9$	L
Deck lattice girder bridge.....	$W = 100 + 8$	L
Half through plate girder bridge with floor.....	$W = 100 + 12$	L
Same with ties on shelf angle.....	$W = 200 + 8\frac{1}{2}$	L
Same with trough floor.....	$W = 600 + 10$	L
Riveted through truss bridge.....	$W = 400 + 6$	L
Riveted deck truss bridge, ties on top chord.....	$W = 200 + 7$	L
Pin through truss bridge.....	$W = 400 + 5\frac{1}{2}$	L
Pin deck truss bridge with stringers.....	$W = 400 + 6$	L
Pin deck truss bridge, ties on top chord.....	$W = 300 + 6$	L

W = weight of steel, lbs. per lin. ft.

L = span in feet.

Railway Trestles.—Assumed loads same as above; weight of spans as above. Weight of bents and bracing is 9 lbs. per sq. ft. of side profile from ground to base of rail.

Mr. Tyrrell also gives the following formulas for the weights of single track railway bridges, for spans of 30 to 234 ft., designed according to Cooper's E 50 loading:

Deck plate girders, $W = 100 + 12 L$.

Through plate girders, $W = 500 + 12 L$.

Through truss spans, $W = 600 + 7 L$.

W = weight in lbs. per lin. ft.

L = span in feet.

Add 90% for double track bridges.

Johnson's "Modern Framed Structures" gives the following formulas for the same loading:

Deck plate girders, $W = 150 + 12 L$.

Through plate girders, $W = 500 + 12 L$.

Through truss spans, $W = 650 + 7 L$.

Cooper's E 50 loading provides for a train of two "consolidation engines" (177½ tons each, including tender), followed by a uniform live load of 5,000 lbs. per lin. ft.

Formulas for Weight of Electric Railway Bridges.—Mr. H. G. Tyrrell gives the following formulas for weight of single track electric railway bridges of 5 ft. to 200 ft. span. The weights include steel only, without safety stringers. The live load is assumed to cover the span from end to end. The details are figured for riveted joints.

I-beam spans of 5 to 20 ft., $W = 50 + 5 L$.

For truss spans of 40 to 200 ft., loaded with 15-ton cars, or 1,000 lbs. per ft., $W = 200 + 0.8 L$.

For truss spans of 20 to 180 ft., loaded with 30-ton cars, or 2,000 lbs. per lin. ft., $W = 250 + 1.5 L$.

For deck plate girder spans, loaded with 2,000 lbs. per lin. ft., $W = 30 + 5 L$.

W = weight of steel per lin. ft.

L = span in feet.

Electric railway trestles: Weights of spans same as above; weights of bents and bracing is 6 lbs. per sq. ft. of side profile from ground to base of rail.

Weights of Bridges, Ill. Central R. R.*—The Department of Bridges and Buildings of the Illinois Central Railroad has made standard designs of steel bridges of all ordinary spans, and has plotted the weights of steel in each type of bridge. From the curves thus plotted certain formulas have been derived for ascertaining the weight (*W*) of the steel in a bridge of any given span. It will be noted that these formulas are not like those found in text books.

Among the valuable diagrams of weights of standard bridges on the Illinois Central is one that gives the weight of draw (swing) bridges, from 75 to 450 ft. span. We do not recall ever having seen similar data for swing bridges. From the diagrams, we have prepared the tables that follow.

The formulas and tables are for class "R" loading, which is as follows:

"For all single track spans use equivalent uniform loads due to two 161.5-ton engines with a total wheel base of 104 ft., followed by a uniform train load of 4,600 lbs. per lineal foot of track.

"For double track spans, of either two or three trusses, and up to 150 ft. span, use equivalent uniform loads due to full engine and train loading as above on each track.

"For double track spans, of either two or three trusses, and over 150 ft. span, use equivalent uniform loads due to full engine and train loading on one track and uniform train load on the other.

"The weight of track will be assumed at 420 lbs. per ft. The weight of steel will be taken from the diagrams."

The weights of spans of intermediate length can be interpolated from the data given in the following tables:

WEIGHTS OF STEEL IN SINGLE TRACK DRAW BRIDGES.

Span, ft.	Without provision for ballast floors, lbs.	With provision for ballast floors, lbs.
75.....	80,000	100,000
100.....	120,000	150,000
125.....	170,000	215,000
150.....	230,000	280,000
175.....	295,000	360,000
200.....	365,000	450,000
225.....	450,000	550,000
250.....	545,000	660,000
275.....	655,000	800,000
300.....	785,000	970,000
350.....	1,100,000	2,320,000
400.....	1,440,000	1,690,000
450.....	1,800,000	2,090,000

Note.—Weights of intermediate spans of swing bridges may be interpolated. For weights of double track spans with three trusses add 85% to the above weights. The spans given in the above table are from c. to c. of end bearings.

Formulas for Weight of Highway Bridges.—Mr. H. G. Tyrrell gives the following formulas for the weight of steel in highway truss bridges:

$$\text{With sidewalks, } W = 2.8 + \frac{L}{11.3}$$

$$\text{Without sidewalks, } W = 5 + \frac{L}{9.5}$$

L = length of span in feet.

W = weight of steel per sq. ft. of floor, including both carriage-way and walk. The weight includes bracing and shoe plates, but not joists or floor. These formulas were based upon designs of through truss spans from 50 to 150 ft., for roadways ranging from 14 to 20 ft. wide. The trusses are riveted. The live load assumed was 80 lbs. per sq. ft. for trusses and 100 lbs. per sq. ft. floor beams, or a 5-ton wagon. These bridges have timber joists and a floor composed of two layers of plank.

The following formulas are for plate girder highway bridges having 16 to 24 ft. roadway and 20 to 80 ft. span, loading same as above.

$$\text{Through plate girder } W = 3 + \frac{L}{4.25}$$

$$\text{Deck plate girder, } W = 2.1 + \frac{L}{5}$$

W = weight of steel per sq. ft. and does not include the timber stringers and plank floor.

For highway bridges with solid floors (assumed dead weight of floor, 150 lbs. per sq. ft.), Mr. Tyrrell gives the following formulas:

$$\text{Deck plate girder bridges, } W = 3 + \frac{L}{2.6}$$

$$\text{Half through girder bridges, } W = 3 + \frac{L}{2.4}$$

$$\text{Truss bridges, } W = 3 + \frac{L}{4}$$

Weight of a 465-ft. Span Highway Bridge.*—The longest highway truss span in America was built in 1901 across the Miami River at New Baltimore, Ohio. It has a span of 465 ft. c. to c. of end pins, and a depth of 66 ft. at the middle. The pin connected trusses are 25 ft. apart in the clear. The bridge is designed for a live load of 2,600 lbs. per lin. ft., with a live load of 100 lbs. sq. ft. on the floor system and a 6-ton road roller as a concentrated load. The floor system consists of plate girder floor beams, I-beam stringers, and 2½-in. plank floor. There is no sidewalk and no street railway track. The weight of the bridge is 1,000,000 lbs., or 2,150 lbs. per lin. ft. or 86 lbs. per sq. ft.

Weight of a 406-ft. Span Highway Bridge.*—A very long highway truss span was built in 1899 across the Miami River at Hamilton, Ohio. The span is 406 ft. c. to c. of end pins. The trusses are 50 ft. deep at the middle and spaced 26½ ft. c. to c. The roadway is 22 ft. wide, and the two cantilever sidewalks are 6 ft. wide each, making a total floor width of 34 ft. The trusses are calculated for a dead load of 5,000 lbs. per lin. ft. of span and a live load of 2,720 lbs. per lin. ft. of span, or 80 lbs. per sq. ft. of floor. The floor system is calculated for a 20-ton roller on two axles 12 ft. apart, or a 16-ton electric car. The floor of the roadway is asphalt blocks on concrete laid on buckle plates, supported by I-beam stringers. The sidewalks are concrete slabs. The total weight of steel in the bridge is 1,300,000 lbs.

Weight and Cost of a Highway Bridge, 120-ft. Spans.*—A steel highway bridge was built in 1905 across the Wabash River at Terre Haute, Ind. It is 812 ft. long between abutments, and consists of 6 spans of 120 ft. each and one 75-ft. span in the center. The roadway is 50 ft. wide, and there is an 8-ft. cantilever sidewalk

**Engineering-Contracting*, Oct. 7, 1908.

on each side, making a total floor width of 66 ft. It is a deck bridge, and each span has two riveted trusses 52 ft. c. to c., with three intermediate plate girders. The roadway is paved with brick. The total weight of steel in the bridge is 4,144,000 lbs. including 88,000 lbs. of street car rails. There are 2,330 cu. yds. of concrete in the two abutments and 3,900 cu. yds. in the six piers; there are 718 piles. The piers average 50 ft. high. The substructure cost \$78,700, and the superstructure cost \$192,500, a total of \$271,200, by contract, including the removal of an old bridge and the building of a temporary bridge, which is equivalent to \$234 per lin. ft., or \$6 per sq. ft. of floor area.

Weight of a 450-ft. Span Highway Swing Bridge.^a—A highway swing span of unusual length was built across the Connecticut River in 1896. The bridge is 450 ft. long. The trusses are 26 ft. c. to c., providing for one line of electric cars and two lines of carriages. The floor is designed to carry 100 lbs. per sq. ft., 14 ton electric cars or a 10 ton wagon. The trusses are designed to carry a live load of 1,600 lbs. per lin. ft. for chords and 2,000 lbs. for web. The floor consists of 4x14-in. yellow pine stringers spaced 2½ ft. apart, supporting two layers of plank, 3 in. and 2 in., respectively. The stringers for the car track are 15-in. steel beams weighing 42 lbs. per ft. There are 23 panels, depth 21 to 56 ft. The turntable is rim bearing. The drum is 4 ft. deep and 31 ft. diameter. Three 25-HP. motors are used, one for turning and two for blocking up the ends. An extra motor is provided. To open takes the motor 30 seconds. Working on 16-ft. levers the bridge is turned by four men in 8 minutes. The total weight of draw-bridge superstructure, including drum and flooring, is 1,330,000 lbs.

Weight of a 520-ft. Double Track Swing Bridge.^a—The longest swing span in the world is the Interstate bridge. It is a double track railway draw bridge, built in 1903, across the Missouri River at East Omaha, Neb. The trusses were designed to carry a live load of 11,180 lbs. per lin. ft. of bridge. This heavy load was allowed in case it should be desired to provide a cantilevered roadway and sidewalk 16 ft. wide on the outside of each truss. The weight of this 520-ft. draw span is 3,900,000 lbs. There were also 9 plate girder 60-ft. spans in the approach, having a total length of 575 ft., and a total weight of 1,773,000 lbs. The pivot pier was sunk to bed rock, a depth of 120 ft. below low water, by open dredging inside a steel cylinder.

The following are the quantities in the substructure:

	Cu. Yds.
Mass in cribs and pneumatic caissons of 2 piers 30 ft. deep..	4,130
Mass in base of pivot pier.....	5,390
Mass in bases of 8-pile piers and 2 abutments.....	2,330
Masonry in shafts of 4 large piers.....	2,135
Concrete in shafts of 8 shore piers and 2 abutments.....	1,550
	Lin. Ft.
Piling below bases of 8 shore piers and abutments.....	19,900
	Lbs.
Steel in pivot pier "well" or open caisson.....	600,000

^aEngineering-Contracting, Oct. 7, 1903.

The "4 large piers" above mentioned are the pivot pier of the draw span and its two rest piers, and a third rest pier for an old existing draw span.

The contract price for this 520-ft. swing bridge and approaches was \$660,000.

Weight of a 450-ft. Double Track Swing Bridge.*—A double track draw bridge, with 5 approach (single track) spans, was built in 1905 across the Tennessee River for the Illinois Central Ry., to replace a lighter steel bridge built 17 years previously. The draw bridge is 450 ft. long, and about 25 ft. c. to c. of trusses. Three of the approach spans are 300 ft. each, and two are 150 ft. each, and are all single track, the trusses being 17½ ft. c. to c. The weights of steel in these spans are as follows:

	Lbs.
1 double track draw span (450 ft.) and turntable.....	2,576,000
3 single track spans, 300 ft. each.....	4,074,000
2 single track spans, 150 ft. each.....	764,000
Total	7,414,000

The price for the draw span was 4.45 cents per lb. ready to assemble; and the price for the pin connected truss spans was 3.64 cents per lb. The cost by contract for erection was \$90,000, which is about 1¼ cents per lb. The pivot pier is 62 ft. high, and 47 ft. diameter. It contains 873 cu. yds. of concrete footing and 1,356 cu. yds. of concrete above the footing, or a total of 2,229 cu. yds. and 16,200 lbs. of reinforcing rods. It rests on 305 piles.

Weight of a 438-ft. Single Track Swing Bridge.*—As a part of the single track bridge, built in 1899 over the Mississippi River, for the Davenport, Rock Island and Northwestern Ry., there are one 361-ft., three 296-ft., and three 200-ft. pin-connected truss spans, beside a 438-swing span which is described subsequently. The trusses are designed for Cooper's Class E 35-train load, and the floor system for Class E 40. The trusses are 18½ ft. c. to c. The weights of each span is as follows:

	Lbs.
438-ft. swing span (including machinery).....	1,400,600
361-ft. span (c. to c. end pins).....	1,038,100
296-ft. span (c. to c. of end pins).....	742,400
200-ft. span (c. to c. of end pins).....	410,000

Weight and Cost of a 334-ft. Four Track Swing Bridge.*—A four track swing bridge was built in 1900 across the Chicago Drainage canal at West 46th street, Chicago, for the Chicago & Western Indiana R. R. It is unique among four track swing bridges in that it has two trusses instead of three. By this arrangement the center pier is only 43 ft. diameter, thus saving about 20 ft. of length over a three-truss bridge that gives the same clear waterway. The bridge is 334 ft. long c. to c. of end bearings. It is 29½ ft. c. to c. of trusses, two of the tracks being supported on cantilever floor beams outside the trusses. The total width is 57 ft. The live load, continuous girder of four supports, is 4,980 lbs. per lin. ft.

*Engineering-Contracting, Oct. 7, 1908.

on the adjacent inside track, 4,200 lbs. per lin. ft. on the adjacent outside track, with no load on the distant outside track.

The weight of steel and iron is 2,692,000 lbs., exclusive of the operating machinery.

The pier is octagonal, 44 ft. diameter, over coping, masonry shell 7 ft. thick, filled with earth inside, is 30 ft. high and rests on clay. The substructure cost \$51,352, the contract prices being: Excavation, 51 cts.; concrete, \$7.30; stone masonry, \$13.35 per cu. yd. The superstructure cost \$131,293, or nearly 4.9 cts. per lb. including the floor. The total cost was \$182,746, or \$547 per lin. ft. of bridge, or \$137 per lin. ft. of track.

Weight of a 231-ft. Single Track Swing Bridge.*—A single track swing bridge was built across the St. Joseph River, for the Pere Marquette Ry., to replace an older span having become too light for modern locomotives. The bridge is 231 ft. c. to c. of end floor beams, and 17 ft. 8 ins. c. to c. of trusses. It was designed for Cooper's Class E loading, and its weight is 600,000 lbs. It is operated by a 30-HP. gasoline engine which opens or closes it in one minute.

Weight of a 216-ft. Double Track Swing Bridge.—A double track swing bridge was built in 1899 across Kinnickinnic River, near Milwaukee, for the Chicago & Northwestern Ry., to replace a single track pin-connected bridge built 19 years previously. It is a riveted lattice truss draw bridge, 216 ft. long, trusses 27 ft. apart in the clear, and designed for a load of two 131½-ton engines followed by a train weighing 4,000 lbs. per lin. ft. on each track. Its weight is 1,200,000 lbs. including track, machinery, etc.

Weight and Cost of a 1,504-ft. (3 Spans) Cantilever Double Track Bridge.*—The longest cantilever railway bridge in America is a bridge finished in 1903 across the Monongahela River at Pittsburgh, for the Wabash R. R. It is 1,504 ft. long exclusive of approaches. The channel span is 812 ft. c. to c. of piers, and each of the shore spans is 348 ft. c. to c. of piers. The steel towers are 138 ft. high, and the depth of the suspended span is 60 ft. The live load consists of two consolidation engines (on each track) followed by a train load of 4,500 lbs. per lin. ft. The weight of the superstructure is 14,000,000 lbs., or 9,300 lbs. per lin. ft. The cost of substructure and superstructure was \$800,000, or \$533 per lin. ft.

The four piers were sunk to rock by the pneumatic caisson process. The height of the four piers averaged 110 ft., of which 35 ft. is below low water.

Weight and Cost of a 1,296-ft. (3 Spans) Cantilever Double Track Bridge.*—A double track cantilever bridge was finished in 1903 across the Ohio River, at Mingo Junction, Ohio, for the Wabash R. R. It is 1,296 ft. long exclusive of approaches. The channel span is 700 ft. and each of the two shore spans is 298 ft. c. to c. of piers. The steel towers are 109 ft. high, and the depth of the suspended span is 51½ ft. Two of the piers have caisson founda-

**Engineering-Contracting*, Oct. 7, 1903.

tions and are 115 ft. high, 25 ft. of which is below low water level. One pier is 100 ft. high, of which only 10 ft. is below low water. There is an abutment (instead of a fourth pier) 40 ft. high. The weight of the superstructure is 12,000,000 lbs. exclusive of approaches. The cost of the substructure and superstructure was \$750,000, or \$577 per lin. ft.

Weight and Cost of a 2,750-ft. (5 Spans) Cantilever Double Track Bridge.*—A double track cantilever bridge was finished in 1905 across the Mississippi River at Thebes, Ill., for the Illinois Central and other railways. It has a length of 2,750 ft. (exclusive of concrete approaches) and consists of 5 spans: one 671 ft., two 521 ft., and two 518 ft., measured center to center of piers. The steel superstructure weighs 24,000,000 lbs., and cost \$1,400,000, and the substructure cost \$600,000, a total of \$2,000,000, which is \$800 per lin. ft. The piers have an average height of about 115 ft. from the cutting edge of the caisson to the top of the pier, and the water averages 20 ft. deep when low. One pier was sunk to a depth of 40 ft. below low water. There is a double track concrete viaduct approach on each side, having a total length of about 1,200 ft., consisting of 45-ft. arches. The height of this viaduct is about 100 ft., and its cost was \$300,000, or about \$250 per lin. ft.

Weight of a 1,380-ft. (3 Spans) Cantilever Highway Bridge.*—A cantilever highway bridge was finished in 1903 across the Ohio River at Marietta, Ohio, for the Ohio River Bridge and Ferry Co. Its length is 1,380 ft. exclusive of two approach spans of 220 ft. each and a plate girder viaduct 640 ft. long, but with these the total length is 2,460 ft. The width is 28 ft. c. to c. of trusses, or 25 ft. clear width of roadway including a 4½-ft. sidewalk. The live load for the trusses was assumed at 60 lbs. per sq. ft.; and for the floor system it was assumed at 80 lbs. per sq. ft. or a steam roller of 15 tons. The cantilever is of peculiar design, due to necessity of providing two channels and of placing one of the piers in a shallow part of the river. The length of the main channel span is 650 ft.; the south anchorage span is 600 ft.; the north anchorage span is 130 ft.; all c. to c. of piers. The trusses are pin connected. The floor system consists of plate girder floor beams, timber stringers, and plank floor. The weight is 4,500,000 lbs., including the approach spans and the viaduct.

Weight and Cost of a Scherzer Highway Lift Bridge.†—A Scherzer rolling lift highway bridge was built in 1897 across the Chicago River at Halsted street. Length of movable part, 176 ft., divided into two leaves 38 ft. long, giving a clear span of 121 ft. between faces of abutments and 109 ft. between protection piles; length of each of the two anchor spans, 60 ft.; total length 276 ft.; width of carriageway, 34 ft. c. to c. of trusses; width of each sidewalk, 7¼ ft. center of truss to center of hand rail; total width, 50 ft. The bridge was designed to carry 100 lbs. per sq. ft., or an 18-ton motor car followed by trailers weighing 15 tons, each on an 8 ft. wheel

**Engineering-Contracting*, Oct. 7, 1903.

†*Engineering-Contracting*, Dec. 3, 1903.

base and having 37 ft. length. The weight of superstructure, including the 50 ft. approach spans, is 320 tons, of which 300 tons is counterweights. The weight of the machinery is 70 tons. Each leaf is operated by a 50 HP. motor. It requires an average of 40 HP. to open each leaf, and about the same for closing, the time required being $\frac{1}{2}$ min. to open and the same to close. The cost of the bridge to the city was:

Substructure	\$ 34,500
Superstructure	55,400
Machinery	13,500
Electrical equipment	5,400
Engineering, inspection, temporary foot bridge and incidentals	14,740
Total	\$123,600

Cost of a Scherzer Highway Lift Bridge.*—In 1894 a Scherzer rolling lift highway bridge was built across the Chicago River, on Van Buren street, Chicago. The span is 115 ft. c. to c. of bearings, giving a clear channel of 109 ft. It has 2 roadways of 21 ft. c. to c. of trusses, and 2 sidewalks of 8½ ft. each. The piers are of concrete and sandstone masonry resting on piles. Each leaf of the bridge has 3 trusses, and is counterweighted with 120 tons of cast iron. The floor is plank, resting on steel I-beams. Two 50 HP. motors operate each leaf. Tests have shown that it requires an average of 60 HP. to raise one leaf at a time, and 96 HP. to raise both sides simultaneously.

Exclusive of engineering and inspection, the bridge cost:

Superstructure	\$ 73,100
Substructure	79,600
Electric equipment and machinery	11,150
Total	\$163,850

Weight of a Scherzer Railway Lift Bridge.*—A double track bascule bridge of the Scherzer type was built in 1904 to replace a draw bridge built 17 years previously, the draw bridge having become too light for the traffic on the Central R. R. of New Jersey. The bridge is part of the Newark Bay crossing. The bridge consists of two lift spans, back to back, across two separate channels. Each of these spans is 120 ft. c. to c. to center of piers, or 110 ft. between piers; but, due to the skew, the clear channel width is only 85 ft. Each span weighs 2,000,000 lbs., about half of which is in the cast iron counterweight, leaving 1,000,000 in the span alone.

Weight of a Scherzer Railway Lift Bridge.*—A rolling lift bridge of the Scherzer type was built in 1899, at the Fort Point Channel, Boston, for the New York, New Haven and Hartford Railroad. It is a skew bridge, the skew being 42°. One truss is 113 ft. long, the other being 84 ft., and the distance from center to center of chords is 27 ft. The weight of this double track bascule bridge is 381,200 lbs. The counterweights weigh 3,100 lbs. The time to operate the bridge one way is 35 secs. with a 60 HP. motor.

*Engineering-Contracting, Dec. 2, 1908.

Cost of a Page Highway Lift Bridge.*—A trunnion bascule highway bridge was built in 1901 across the Chicago River at Ashland avenue. The bridge is of the Page type and consists of two leaves, 168 ft. c. to c. of trunnions. The bridge is 258 ft. long, and has a clear waterway of 140 ft. between fender piles. The trusses are 40 ft. c. to c. carrying a 36-ft. clear roadway with two 8-ft. cantilever sidewalks, making a total of 52 ft. of floor width. The bridge is designed for a live load of 100 lbs. per sq. ft. for the roadway and 80 lbs. for the sidewalks; concentrated load 20 tons on two axles 12 ft. c. to c. The weight of steel in each leaf is 340,000 lbs. There are about 620,000 lbs. of cast iron for counterweights of each leaf. The substructure required the following quantities:

Excavation	6,540 cu. yds.
Concrete	2,820 cu. yds.
Sheet piling and bracing	250,000 ft. B. M.
Timber in protection work and dock.....	28,500 ft. B. M.
Piles in protection work and dock.....	7,300 lin. ft.
Piles in coffer dam	2,100 lin. ft.
The contract price was:	
Substructure	\$ 25,540
Superstructure	91,200
Total	\$116,740

Cost of a Page Railway Lift Bridge.*—A double track single-leaf bascule bridge of the Page type was built in 1907 over the Chicago River by the Chicago & Alton Ry. It has a span of 150 ft., and there is an approach span of 64 ft. The superstructure, including electrical equipment for operation, cost \$115,000. The substructure, including the removal of an old pivot pier and some dredging of the channel, cost \$50,000, making a total cost of \$165,000. The substructure contained 3,200 cu. yds. of concrete.

Cost of a Trunnion Bascule (Lift) Bridge.*—A trunnion bascule highway bridge was built at Clybourn Place, Chicago, in 1902, according to designs of John Ericson, City Engineer. The bridge is a fixed center, double leaf, counterbalanced bascule, 128 ft. c. to c. of pivot bearings, and 120 ft. c. to c. of piers, with a clear channel of 100 ft. between the guard piles that protect the piers. The length over all is 180 ft. Each leaf has three through trusses, 21 ft. c. to c., and the total width of the bridge is 60 ft., the sidewalks being carried on 9-ft. cantilever brackets. The motive power is two 28 HP. motors. The bed of the river is about 40 ft. below the lower chord of the bridge, and the water is 23 ft. deep. The substructure is of concrete resting on piles. The contract price was \$69,000 for substructure and \$86,000 for superstructure, or a total of \$155,000. The weight of each leaf is 640,000 lbs. including structural steel, cast iron rack, timber and counterweights. This is equivalent to nearly \$1,300 per lin. ft. of span between piers, or \$860 per lin. ft. of total length.

Cost of a Trunnion Bascule (Lift) Bridge.*—A trunnion bascule highway bridge was built in 1903 at Northwestern avenue, Chi-

*Engineering-Contracting, Dec. 2, 1903.

cago. It consists of two leaves, and the span between centers of trunnions is 205 ft., while the span between abutments is 190 ft., and the clear width of the channel is 165 ft. between the timber protection works. There are three lines of trusses 21 ft. c. to c., and 9 ft. cantilever sidewalks, making a total width of 60 ft. There are two approach spans, one of 75 ft. and one of 17 ft. The total length of the bridge is 361 ft., and it contains 2,180,000 lbs. of structural steel, 1,400,000 lbs. of counterweight pig and cast iron, and 200,000 lbs. of machinery. The substructure consists of 4,500 cu. yds. of concrete and 300 cu. yds. of rubble curb walls for the approaches. The contract price for the substructure was \$88,200, and \$208,500 for the superstructure, a total of \$296,700.

Weight of an 840 ft. Span Arch Bridge.*—The Niagara Falls and Clifton steel arch bridge was built in 1895-1898. It consists of a main span of 840 ft. and two end spans, one of 190 ft. and the other of 210 ft., giving a total length of 1,240 ft. The main arch springs from the solid rock. The arch is two-hinged, parabolic, and has a rise of 137 ft. The end spans are pin-connected, inverted bow string trusses. The bridge carries on one level two lines of trolley car tracks, two carriageways and two sidewalks, having a total width of 48 ft. There are 1,637 cu. yds. of masonry in the substructure. The materials used in the main span were as follows:

	Lbs.
Two-arch trusses, not including laterals.....	1,673,356
Laterals of arch	383,522
Bents, including lateral bracing.....	450,577
Longitudinal bracing	150,705
Skewbacks and shoes	226,634
Floor system	766,287
Total	3,651,081
In addition there were:	
New York end span.....	344,862
Canadian end span.....	371,723
Hand rail and floor fastenings.....	83,048
Miscellaneous (field rivets, etc.).....	81,323
Grand total	4,532,047

There were 246,000 ft. B. M. of timber in the permanent flooring.

Weight and Cost of a 195 ft. Span Arch Bridge.*—A steel arch highway bridge was built in 1900 across Nine-Mile Run, at Pittsburgh. The total length is 444 ft. The carriageway is 36 ft. wide, on each side of which is 6½-ft. cantilever sidewalk, making a total width of 49 ft. of floor. It consists of a steel arch span, 195 ft. c. to c. of pins, and a steel viaduct approach of five 24-ft. plate girder spans on each side of the arch span. The arch span is a pair of three-hinge plate girders. The sidewalks and carriageway are made of buckle plates and concrete, the carriageway being paved with asphalt. The arch has a rise of 59 ft.; and, as the ground rises rapidly from the skewbacks toward each end of the bridge, the average height of the viaduct approaches is about half this rise, or 30 ft.

**Engineering-Contracting*, Dec. 2, 1903.

The materials were as follows:

Structural steel (lbs.).....	1,457,000
Railing, 889 lin. ft. (lbs.).....	60,000
Stone Masonry (cu. yds.).....	1,410
Concrete (cu. yds.).....	287
Paving on roadway (sq. yds.).....	1,800
Paving on sidewalk (sq. ft.).....	5,500
Curb (lin. ft.).....	890

The total contract cost was \$86,534, including \$536 for mill, shop and field inspection of the steel, or 70 cts. per ton for inspection.

This is equivalent to \$195 per lin. ft., or \$4 per sq. ft. of floor.

Weight of a 207 ft. Span Arch Bridge.*—A single track, three-hinged steel arch bridge was finished in 1902 across the Menominee River, Michigan, for the Chicago, Milwaukee & St. Paul Ry., replacing a steel bridge built 17 years previously, which had grown too light for the traffic. The bridge is 355 ft. long, consisting of a three-hinged arch of 207 ft. span and four plate girder approach spans of 39½ ft. each. The trusses are 22 ft. c. to c. The arch has a rise of 52 ft. The bridge is designed according to Cooper's specifications for a live load of two consolidation Class E-50 locomotives and 7,000 lbs. per lin. ft. behind the engine. The weight of steel in the arch span is 480,000 lbs., and in the approach spans it is 150,000 lbs.

Weight and Cost of a 440 ft. Span Arch Bridge.*—A steel highway bridge was built in 1906 in Pittsburg. It is known as the Oakland Bridge. It is 800 ft. long and has a roadway 20 ft. wide, with a 7 ft. cantilever sidewalk on each side. It consists of an arch having a span 440 ft. and a rise of 70 ft., and a steel viaduct approach at each end of the arch, the spans of the approach girders being 30 to 40 ft. each. The arch span consists of two lattice girder arch ribs, abutting on concrete abutments built on the solid rock. The arch is not hinged. The cost of this bridge was \$133,000, which is equivalent to \$173 per lin. ft., or \$4.50 per sq. ft. of floor area.

Cost of Steel Arch Bridge.*—A steel highway bridge was built in 1906 across the Potomac River, at Washington, D. C. The bridge is 1,006 ft. long between abutments, and consists of 6 three-hinged arch spans of 123 ft. each, and one two-leaf bascule span of 103 ft. Each of the arch spans has six plate girder ribs. The bridge is 48 ft. wide between handrails, having two 6½ ft. sidewalks and a 35 ft. roadway. The rise of the arches is 14 ft., and the height of the piers averages about 85 ft. to the spring line. The concrete piers rest on pile foundations. The site of each pier had to be dredged before driving the piles. The low water surface is about 16 ft. below the spring line of the arches. The bridge cost \$375,000, or \$375 per lin. ft., or \$7.80 per sq. ft.

Weight of the Burlington Bridge of the C., B. & Q.†—In 1890 a double track steel railway bridge was built across the Mississippi River, at Burlington, for the C., B. & Q. R. R., to replace a single

* *Engineering-Contracting*, Dec. 2, 1902.

† *Engineering-Contracting*, Nov. 4, 1903.

track iron bridge built 22 years before. The 6 spans of 250 ft. each, weighed 3,340 lbs. per lin. ft. The draw span of 363 ft. weighed 3,980 lbs. per lin. ft. The bridge was designed to carry a moving load of 5,000 lbs. per ft. of double track structure (3,000 lbs. per ft. of single track), this load being increased 50% in estimating the variable effect of a moving load.

The cost of engineering was 5% of the total cost of piers and superstructure.

Weight of a Double Track Draw Bridge, 195 ft. Span.—A double track swing bridge (through riveted truss) was built in 1901 across the Hackensack River, N. J., for the D. L. & W. Ry. Its weight is 1,206,000 lbs. and its length is 195 ft.

Weight of a 533 ft. Span Railway Bridge and of a 323 ft. Draw Span Across the Delaware.—A double track railway bridge was built in 1896 across the Delaware River, at Bridesburg, for the Pennsylvania and N. J. R. R. Co. There are three spans of 533 ft. each, and a draw span of 323 ft. The weight of steel in each of the three 533 ft. spans is 4,182,000 lbs.

The weight of the steel in the draw span with riveted work is 1,505,000 lbs., and the weight of the machinery is 356,000 lbs., total 1,861,000 lbs.

A steel traveler was used to erect the bridge. The traveler was 110 ft. high, 46 ft. wide at the bottom and 81 ft. wide on top. Its weight was 292,000 lbs. without trucks.

Weight of a Highway Cantilever Bridge, 1,024 ft. Long.—Mr. Gustave Kaufman gives the following data relative to the weight of a highway bridge at Cincinnati, built in 1890.

The cantilever bridge has a span of 520 ft. c. to c. of piers, and the shore arms of the cantilever are each 252 ft. long, making a total length of 1,024 ft. This does not include several approach spans on each side.

The weight of metal is as follows:

Shore arms of cantilever	1,276,978
River arms of cantilever	691,360
Suspended span (208 ft.) ..	335,185
Total	2,403,523

It required $\frac{1}{2}$ gal. of paint per ton of metal for two coats.

The bridge trusses were designed for a live load of 80 lbs. per sq. ft. The stringers and floor beams were designed for a live load of 100 lbs. per sq. ft., or a 15-ton steam roller. The roadway consists of 6 lines of iron stringers riveted to iron floor beams, and covered with cross timbers, spaced 30 ins. c. to c., to which are spiked two layers of oak flooring having a total thickness of $5\frac{1}{4}$ ins. The roadway is 2 ft. wide in the clear, and the sidewalks (which are on brackets outside of the trusses) are each $7\frac{1}{2}$ ft. wide in the clear.

Estimating Cost of a Steel Bridge Erection.—The cost of erecting steel bridges should be separated into two main items: (1)

cost of falsework, and (2) cost of erecting the steel. Usually, however, engineers who have published cost data have unfortunately lumped these two items together.

The cost of falsework for any given bridge, and of a traveler of given design, can be estimated from the data given in the section on Timberwork, and from data in the following pages.

It should be remembered that railway plate girder bridges are usually erected with little or no falsework. Railway plate girders up to 80-ft. span, and occasionally up to 120-ft. span, are shipped as single pieces. Short girders are skidded flat into position from the car and then turned on edge. Long girders may be lifted from the cars by galleys frames and lowered to position.

Swing bridges are erected on the pile fender or guard pier, which serves as the falsework. This makes the cost of erection much less than for truss bridges for which falsework must be built.

Steel viaducts are erected with travelers, so that no falsework is required.

The cost of materials and of labor on steel bridges should be recorded in terms of the pound of steel as the unit, or in terms of the ton of 2,000 lbs.

Cost Per Lin. Ft. and Per Sq. Ft.—It is customary to state the cost of railway bridges in terms of the lineal foot of span, while the cost of highway bridges is preferably reduced to the square foot of floor area as the unit. However, it should be remembered that, in either case, the unit cost increases rapidly as the span increases.

The cost of viaducts is often given in terms of the square foot of profile area; but care should be taken to state whether the total profile area is estimated below the base of the railway rail, or below the top of the towers.

Most Economical Span.—Mr. J. A. L. Waddell, M. Am. Soc. C. E., was, I believe, the first to enunciate the following theory (in 1890): "For any crossing, the greatest economy will be attained when the cost per lineal foot of the substructure is equal to the cost per lineal foot of the trusses and lateral systems." Note that the cost of the floor system, being practically independent of the length of the span, does not enter into this generalization.

The following is the demonstration of this theory: Assume a bridge crossing of indefinite length, with the depth to bedrock constant. Let

- S = cost per lin. ft. of substructure.
- T = cost per lin. ft. of trusses and laterals.
- F = cost per lin. ft. of floor system.
- Y = cost per lin. ft. of entire bridge.
- L = length of each span.
- $Y = S + T + F.$

Assuming that slight changes in L will not materially affect the size of the piers, S will vary inversely as L , hence

$$S = \frac{K}{L}, \quad K \text{ being a constant.}$$

But, for slight changes of L , T varies nearly directly as L , hence $T = CL$, C being a constant. Since F is practically a constant, being a function of panel length and not of span length, we have

$$Y = \frac{K}{L} + CL + F,$$

in which Y is to be made a minimum. Differentiating we have

$$dY = -\frac{K dL}{L^2} + C dL, \text{ whence, by putting } \frac{dY}{dL} = 0, \text{ we have } \frac{-K}{L} + C = 0, \text{ or } K = CL.$$

A further differentiation shows that the result corresponds to a minimum. Although no bridge is indefinite in length, and although ledge rock usually is found at different depths, still this same principle may be applied to each pier and the two spans that it helps to support, by making the cost of the pier equal to one-half the total cost of the trusses and laterals of the two spans.

The principle obviously applies to trestles, viaducts and elevated roads.

In an ordinary viaduct, consisting of alternate spans and towers, the cost of all the girders in two spans (one span being over the tower), plus the cost of the longitudinal bracing of one tower, should equal the cost of the two bents of the tower plus the cost of their masonry pedestals.

In an elevated railway, the cost of the stringers or girders of one span should equal the cost of one bent, including its pedestals.

The Life of Steel Railway Bridges.*—Considering the economic importance of the subject, it is astonishing that no tabulated statistics as to the life of American steel railway bridges can be found in print.

Bridge engineers are accustomed to denominate wooden bridges as "temporary," while they call steel bridges "permanent." The annual reports of railway managers to stockholders contain these expressions, and there is a general acquiescence in the propriety of their application. But the facts are that steel railway bridges are so far from being permanent that they, too, should be classed as temporary.

We must not be misunderstood as decrying the lasting qualities of steel itself, for there is abundant evidence that iron and steel are exceedingly lasting under certain conditions. Let us illustrate.

The "first iron railway bridge" was built in 1823, for the Stockton & Darlington Ry., at West Auckland, England, and was not removed until 1903, after 80 years of service. This bridge is illustrated and described in the "Railroad Gazette," July 8, 1904, p. 125. The bridge was, in fact, an iron trestle with cast iron posts and four iron spans of 12 ft. 8 ins. each. The spans consisted of double arch members of wrought iron united by cast iron struts.

**Engineering-Contracting*, Oct. 7, 1903.

As is well known, the life of an iron or steel railway bridge is not limited by the durability of the bridge, but by its ability to withstand the steadily increasing loads imposed upon it.

The average age of the 1,000 locomotives in use on the Northern Pacific Railway is 10.4 years. There are in service (or, at least, there were two years ago) several locomotives 34 years old. This road has been in existence so long that its rolling stock may be said to have reached a condition of normal renewals. When a condition of normal renewals is reached as to cross ties, the life of the average tie is just twice the age of the existing average tie. If the age of the average tie is found to be 5 years, and a condition of normal renewals of 10 per cent per annum exists. In like manner, rolling stock ultimately approximates a condition of normal renewals. It does not reach exactly that condition, due to the steady growth of traffic on the railway. But, if we multiply the 10.4 years by 2, we have 20.8 years, which is the approximate average life of locomotives on the Northern Pacific Ry. Due to the increase in the number of locomotives each year, the true average life is slightly greater than the 20.8 years thus ascertained.

Since there has been a complete renewal of locomotives in about 20 years, and since the locomotives have grown progressively heavier, it is logical to look for a renewal of steel bridges in about the same length of time and in fact that is what has occurred. Table I shows the life of 10 bridges.

TABLE I.—SHOWING LIFE OF TEN RAILWAY BRIDGES.

Item No.	Name of R. R.	Location of Bridge.	When Built.	Life, Years.
1.....	C. M. & St. P.....	Rock River.....	1884	19

Average of the above.....				18.1

It will be noted that the average life of these 10 steel railway bridges has been 18.1 years. When it is remembered that the life of an uncovered Howe truss wooden bridge is rarely less than 10 years and is frequently 20 years (see committee report of the Association of Railway Superintendents of Bridges and Buildings, October, 1899), what becomes of the designation "permanent" as applied to steel in contrast with wooden railway bridges? The consensus of opinion given in the report above cited was to the effect that a Howe truss, properly housed in, would last more than 40 years. A housed in wooden highway bridge, of the Howe truss type, was taken down at Zanesville, Ohio, after 65 years of service.

With such statistics before us, we are forced to conclude that most railway bridge engineers have fallen into serious error in not giving proper consideration to the temporary character of steel railway bridges as heretofore designed.

While we cannot predict with accuracy what the increase in railway bridge loading will be in the future, there is nothing more certain than that an increase will occur. Since the first railway was built, there has been a steady growth in the size of locomotives and cars. When will it cease? No man can tell. Therefore, if we plan for the future upon the teachings of the past 80 years, we must either make due allowance for increased weight of rolling stock when designing steel railway bridges, or we must cease calling them "permanent" and apply to them, as to timber bridges, their proper designation, "temporary."

In addition to the important bearing that such statistics as are here given have upon bridge design, there is the further importance of such data in solving problems of railway appraisal. In making his appraisal of railways of Washington for the State Railroad Commission, Mr. H. P. Gillette had to make an estimate of the "present value" of all structures. Nearly all the steel railway bridges in Washington are comparatively new, and, as the appraisal of the railways was made primarily for rate making purposes, Mr. Gillette assigned no depreciation to the steel bridges. This gave the railways more than "the benefit of the doubt," for there can be no doubt that there is no real permanency in steel railway bridges as at present designed. For taxation purposes, it is clear that a depreciation of about 5 per cent per annum should be made from the first cost of all steel railway bridges.

Even a casual study of bridge books and bridge literature must impress an engineer with the lack of attention that engineers have given to this all important subject of the life of bridges. The text books treat the problems of bridge design largely as problems in pure mathematics and mechanics, and ignore many equally important principles of bridge economics. Most of the designers of reinforced concrete railway bridges are making the same blunders that have characterized the designers of steel railway bridges, namely, designing for present loadings without provision for the future.

Life of Railway Bridges.—Mr. J. E. Greiner states that the life of iron or steel railway bridges "has been scarcely 25 years," due to the steady increase in the weight of locomotives. He gives the following table of weights of locomotives in the Baltimore & Ohio Ry., for 60 years:

Year.	Weight in tons.
1835.....	10.7
1851.....	37.3
1863.....	45.4
1873.....	52.6
1881.....	54.3
1886.....	56.6
1890.....	66.6
1894.....	80.4
1895.....	95.0 (electric)

The increase between 1835 and 1895 has been 75%, or 7½% per annum. The increase between 1835 and 1895 has been 783% for 60 years, or 13% per annum.

Amount of Work Done Per Man in a Large Bridge Works.—At the Pencoyd works of the American Bridge Co. the following was the amount of work done in the first half of the year 1901. The number of men employed was 765 (of whom 98 were draftsmen) and the output was 82,600,000 lbs. in 6 mo., or nearly 13,800,000 lbs. per mo. The average output per man per month was, therefore, 18,300 lbs. The output of each of the different classes of men was as follows per month:

	Pounds.
Draftsmen (98 men).....	140,000
Templaters (30 men).....	455,000
Bridge shop	21,300
Forge	11,000
Eye-bar shop	35,400

The output per draftsman was found by dividing the total output of the works by the number of draftsmen employed; in like manner the output per templater was calculated; but the output of each man in the bridge shop, forge and eye-bar shop was calculated only on the basis of the number of pounds handled in each of those departments.

Cost of Erecting A., T. & S. F. Ry. Bridges.—The average cost per ton of the bridges erected on the Atchison, Topeka & Santa Fe Ry., in 1907, all of which were on the main line of this railway, and consequently made it necessary to contend with all trains was as follows:

	Per ton.
Trusses, 984 tons erected.....	\$4.63
Girders, 2,784 tons erected.....	5.49
I-beams, 2,837 tons erected.....	2.88

All the girders and I-beams were erected with steam wrecker and through spans with the derrick car. It will be noticed that the girder work cost more than the trusses, the reason for this being that a good part of the girder work was on second track, where one girder had to be cut apart and moved to the outside and a heavier girder set in its place. The bridge gang traveled over a territory of 5,000 miles and the cost of moving was also charged to the bridges. The riveting was done by hand.

Falsework for a Railway Bridge.*—The new Havre de Grace bridge for the Pennsylvania R. R. in Maryland of 255 ft. and one of 192 ft., is a double track deck truss structure about 4,115 ft. long composed of one 280-ft. swing span and 17 fixed spans from 192 ft. to 255 ft. long. The swing span and the 8 fixed spans were fabricated and erected by the American Bridge Co. The swing span was erected up and down stream on the fender, and the fixed spans were erected on pile trestle falsework. The construction of the falsework trestle, the method of its erection, and the total and unit quantities of lumber used are given in this article from data furnished by Mr. H. F. Lofland, General Manager of Erection, American Bridge Co., Philadelphia, Pa.

*Abstracted from *Engineering-Contracting*, June 5, 1907, but omitting the drawings.

Under the shore span (192 ft.) a falsework of framed bents constructed was employed. In deeper water pile bents were used with the caps directly on the pile tops and every other panel braced. The number of piles in a bent was increased with the increase in the depth of water; for spans 2, 3, 8 and 9 six pile bents were used, and for spans 4 and 7 eight pile bents, while spans 5 and 6 had double bents of eight piles each. The 8-pile double bents were two bents of 8 piles each, the bents being spaced 4 ft. c. to c. The longitudinal bracing was universally 4x8-in. stuff for diagonals and 6x8 in. stuff for horizontals.

The method of construction was to drive the piles for all nine spans complete, then to complete the falseworks for the first five spans and finally to transfer the caps and bracing to spans 6, 7, 8 and 9 from preceding spans as fast as these were erected. The piles ran from 50 to 90 ft. in length and were driven to a penetration of 25 ft. in all spans except 5 and 6, where a penetration of only 20 ft. was permitted. The schedule of piles for the several spans was as follows:

Spans.	No. piles.	Total lin. ft.
2-3.....	48	2,400
3-4.....	48	2,550
4-5.....	64	4,320
5-6.....	128	9,920
6-7.....	128	11,200
7-8.....	64	4,400
8-9.....	48	2,760
9-10.....	48	2,880
Total.....	576	40,430

There were, therefore, about 18 lin. ft. of piling used for lineal foot of span, not counting the posts in the pier bents.

The falseworks were proportioned for a maximum concentrated live load at one corner of the traveler of 25,000 lbs.; it was also proportioned for the following panel loads; 192-ft. span, dead load due to steel superstructure, 45,000 lbs., live load due to hauling out materials, 24,000 lbs.; 255-ft. spans, dead load, 79,000 lbs., live load, 25,000 lbs. As stated above, caps and bracing for spans 2, 3, 4 and 5 were reared in spans 6, 7, 8 and 9. The total falsework in addition to piling was then:

Span.	Description.	Ft. B. M.
1-2—	Bents and bracing.....	22,720
2-3—	Caps and bracing.....	13,147
3-4—	Caps and bracing.....	12,147
4-5—	Caps and bracing.....	20,325
5-6—	Caps and bracing.....	31,824
Total	99,163

This total is exclusive of the timber in the posts of the pier bents. These posts are 12x12 ins., and average about 41 ft. in length; there are four posts to each bent and 17 bents. They contain, therefore, $492 \times 4 \times 17 = 33,456$ ft. B. M., which, added to the above total, gives 132,619 ft. B. M., or 60 ft. B. M. per lineal foot of bridge (river spans). The total weight of steel in the river

spans was 16,000 tons, so that there were used 6.74 lin. ft. of piling and about 22.1 ft. B. M. of falsework timber per ton of steel.

Cost of a Steel Railway Bridge and Foundations.—Mr. W. A. Rogers gives the following data relative to erecting a 4-span single track bridge across Grand River, Mo., for the C., M. & St. P. Ry. in 1895. The 4 spans were 138 ft. long each, and weighed 178,600 lbs. each. The work was done by company forces at the following cost:

<i>Falsework—</i>	
Materials	\$1,606.90
Labor	1,834.89
Train service	150.00
Total	\$3,591.89
<i>Two Pile Piers—</i>	
Material	\$ 420.24
Labor	287.00
Train service	40.00
Total	\$ 747.24
<i>Foundation Three Masonry Piers—</i>	
Material (piles and timber grillage)....	\$ 601.40
Labor	1,773.00
Total	\$2,374.40
<i>Stonework Three Masonry Piers—</i>	
343,080 lbs. stone	\$2,061.83
501 sacks cement	176.90
Miscellaneous material	22.94
Labor	3,485.53
Total	\$5,747.30
<i>Iron Superstructure—</i>	
700,000 lbs. wrought iron.....	\$17,216.91
14,489 lbs. cast iron	195.42
Miscellaneous	21.06
Labor erecting	1,952.97
Train service	96.78
Total	\$19,483.15
<i>Floor—</i>	
Materials	\$1,051.32
Labor	292.82
Total	\$ 1,344.14
<i>Moving the Spans—</i>	
Materials	\$ 136.62
Labor	521.89
Train service	58.20
Total	\$ 716.81
Removing old pile piers, pulling piles, and removing falsework.....	593.05
Removing driftwood (burning).....	938.78
Night watchman	465.50
Engineering	1,145.96
Grand total	\$37,148.22

This is equivalent to nearly \$70 per lin. ft. for the 552 lin. ft.

The first item of falsework includes taking down 4 old Howe truss bridges. The falsework item amounts to \$6.53 per lin. ft., and is equivalent to 0.5 ct. per lb. of iron in the bridge. The erection of the iron cost 0.29 ct. per lb., which added to the 0.5 ct. makes a total of about 0.8 ct. per lb. for erection and falsework, or \$16 per ton.

The stone masonry required 4,800 lbs. of stone in the rough per cu. yd., and cost \$8.04 per cu. yd., of which \$4.87 was labor.

The floor, or deck, cost \$22.22 per 1,000 ft. B. M., or \$2.44 per lin. ft. for labor and materials, of which \$0.52 per lin. ft. was for labor.

The four spans were erected on the old piers and subsequently moved 30 ft. lengthwise on rollers riding on temporary plate girder spans, the cost of this moving was \$179 per span, or 0.1 ct. per lb. It took 6½ days to move the spans, although it took only 15 mins. to pull a span from the old pier to the new, using a locomotive.

Engineering was 3% of the total cost.

Cost of a Steel Bridge of 155-ft. Span.—The following data appeared in *Engineering-Contracting*, Apr. 3, 1907, and relate to the cost of building a steel railway bridge of 155 ft. span (total weight 131 tons), to take the place of an old Howe truss bridge. Two concrete abutments on pile foundations were built at a cost of \$2,600 each, or \$5,200 for both abutments. There was nothing unusual about this abutment work, so its cost will not be given in detail. All work was done by "company forces," and the itemized cost is given below.

Wages were \$3.40 per 10-hour day for foreman, \$2.50 for bridgemen, and \$2.00 for laborers. The engineman on the hoisting engine received \$2.50 a day, and the fireman received \$2.00. In travelling to and from the site of the work, the time of the men amounted to 16 days.

Time travelling, 16 days, at \$2.50.....\$ 40.00

Erecting Traveler—

3 days at \$3.40	\$ 10.20
30 days at \$2.50	75.00
9 days at \$2	18.00

	\$	23.90

Placing and Fitting Ties—

1 day at \$3.40	\$	3.40
7 days at \$2.50		17.50
	\$	20.90

Framing and Fitting Guard Rail—

1 day at \$3.40	\$	3.40
4 days at \$2.50		10.00
2 days at \$2		4.00
	\$	17.40

Boring and Bolting Guard Rail and Ties—

8 days at \$2.50	\$	20.00
------------------------	----	-------

Total labor on superstructure	\$	1,125.00
-------------------------------------	----	----------

This is equivalent to practically \$7.80 per lineal foot of bridge, or \$8.59 per ton. The labor cost per ton of bridge may be summarized as follows:

	Per ton.
General labor, \$215	\$1.64
Unloading steel, \$68.2053
Painting inaccessible parts, \$4837
Removing old deck, \$25.9020
Erecting trusses and floor system, \$390.70	2.98
Riveting and machine bolts, \$283.80	2.17
Timber deck work, \$93.4071
Total	\$8.59

Strictly speaking, the items of labor on the timber deck should not be charged as a part of the cost of work on the steel portion of the bridge. The labor on the ties and guard rails, it will be seen, amounted to 60 cts. per lineal foot of bridge. It will be noted that there is no charge for fuel used by the hoisting engine, nor for transportation charges on the engine and materials for the traveler. The hoisting engine was in use 9 days, so that the fuel item could not have exceeded \$30, and was doubtless much less.

The following is a summary of the total cost of this steel bridge on its concrete abutments:

Two concrete abutments	\$ 5,200.00
Removing old bridge	200.00
Falsework	1,220.00
Bunk house	40.00
Materials in superstructure	7,200.00
Labor erecting superstructure	1,135.00
Engineering and inspection	585.00
Total	\$15,570.00

This is practically \$100 per lineal foot of bridge, including cost of abutments.

It will be noted that the false work cost about \$8 per lineal foot of bridge, and amounted to a little more than the labor cost of erecting the bridge; but this cost of \$1,220 for false work included both labor and materials. The cost of false work for ordinary bridges like this can be estimated as equivalent to the cost of a pile trestle, unless the height of the lower chord of the bridge above the bed of the river is so great as to necessitate building one or more decks of framed bents on top of the pile bents.

Cost of a Steel Bridge of 180-ft. Span.*—In our last issue we gave details of the cost of erecting a railway bridge of 153 ft. span. The general remarks relating to that bridge also apply to the one discussed in this article. Both bridges were through spans, riveted trusses, on concrete piers, erected by company forces. This 180-ft. bridge had a total weight of 172 tons. The cost of erecting the bridge was as follows:

Building Traveler—

1½ days, foreman, at \$3.40	\$ 5 10
11 days, carpenters, at \$2.50	27 50
	\$ 32.60

**Engineering-Contracting*, Apr. 10, 1907.

4 days at \$2.25.....	9.00	
		\$ 22.40

Boring and Bolting Guard Rail and Ties—

7 days at \$2.50.....	\$ 17.50	
1 day at \$2.25.....	2.25	
		\$ 19.75

Taking Out Old Deck—

½ day at \$3.40.....	\$ 1.70	
1 day at \$2.50.....	2.50	
1½ days at \$2.25.....	3.35	
		\$ 7.55

Total labor\$1,461.25

This is equivalent to \$8.10 per lin. ft. of bridge, or \$2.48 per ton.

It will be seen that it took 50 days of labor, including foreman, but excluding work train crew, to erect the bridge, thus making the average wage about \$2.60 per day of 10 hours.

In comparing labor costs per unit of work done, it is always well to state the average wage paid, for, otherwise, serious errors may be made in comparing unit costs given only in dollars and cents. Wages have been rising so rapidly within recent years that the necessity of stating the average wage is more urgent than ever.

The wages of the foreman constituted 7 per cent of the total wages paid.

The cost per ton for erecting this bridge may be summarized as follows:

	Per ton.
Preparing and dismantling plant, \$318.50.....	\$1.85
Unloading steel, \$89.....	.52
Painting inaccessible parts, \$77.65.....	.45
Erecting trusses and floor system, \$420.65.....	2.45
Riveting and machine bolting, \$441.75.....	2.55
Timber deck work, \$113.70.....	.66
Total	\$8.48

It will be seen that the work on the timber deck cost 83 cents per lin. ft. of bridge.

The total cost of this bridge on concrete abutments with pile foundations was as follows:

Two concrete abutments, materials and labor.....	\$ 4,700
Materials for superstructure	9,500
Labor erecting superstructure.....	1,481
Falsework and removal of old bridge.....	2,800
Engineering and superintendence	370
Total	\$18,831

This is practically \$105 per lineal foot of bridge, including abutments.

Cost of Two Steel Truss Bridges of 180-ft. Span, and One Plate Lattice Girder Bridge of 100-ft. Span.*—In our issue of April 10, we gave the detailed cost of erecting a steel bridge of 180 ft. span. The following data relate to two spans, also of 180 ft. each, on which the labor of erection cost was very much less per ton than the cost given in our issue of April 10. This difference appears to have been due to better management and more efficient workmen on the work about to be described. These two 180-ft. spans were erected by a contractor, and the costs are the actual costs to the contractor, exclusive of contractor's profits. The bridges were single track, through, riveted trusses erected with a traveler. The average force engaged was as follows:

1 General foreman at	\$5.00	\$ 5.00
1 Carpenter foreman at	4.00	4.00
1 Sub-foreman at	3.50	3.50
7 Riveters, etc., at	3.25	22.75
10 Bridgemen at	3.00	30.00
3 Carpenters at	2.75	22.00
3 Laborers at	2.50	7.50
1 Stationary engineman at.....	3.25	3.25
1 Water boy at	1.50	1.50
33 Total men	\$3.00	\$99.50

It will be noted that the average wage paid was \$3 per day of 10 hours, as compared with \$2.69 on the bridge described in our issue of April 10. No attempt was made to record the exact cost of each item of the work, but account was kept of the number of

**Engineering-Contracting*, May 3, 1907.

men and the number of days required to perform each item of the work, and the average wage was assumed to be \$3 per man day.

Preparatory Work—

50 Man days traveling at \$3.....	\$ 150.00
50 Man days erecting traveler and derricks at \$3.....	150.00
12 Man days taking down same.....	36.00
40 Man days removing old floor at \$3.....	120.00
20 Man days unloading steel and ties.....	60.00

Steel Work—

70 Man days putting in new steel floor system at \$3.....	210.00
100 Man days erecting steel trusses at \$3.....	300.00
125 Man days riveting.....	375.00

Timber Deck—

20 Man days framing ties at \$3.....	\$ 60.00
30 Man days laying floor at \$3.....	90.00

Painting—

45 Man days, first coat.....	135.00
42 Man days, second coat.....	126.00

Total labor	\$1,815.00
Wear of tools, ropes, etc.....	100.00
Coal for engine and blacksmith.....	70.00

Total\$1,985.00

The steel in each of the two bridges weighed 170 tons, or 340 tons in both bridges, or 1,800 lbs. per lin ft. Summarizing the cost of erection, we have:

	Per ton.
Lost time traveling, \$150.....	\$0.44
Erecting and taking down plant, \$186.....	0.56
Removing old floor system, \$126.....	0.35
Unloading steel and ties, \$60.....	0.18
Steel work, \$385.....	2.60
Timber deck work, \$150.....	0.44
Painting, \$264.....	0.72
Wear of tools, \$100.....	0.30
Coal, \$70.....	0.20
Total	\$5.84

The above does not include the cost of erecting the falsework, but it includes the item of "removing old floor system" or the wooden bridge which was replaced by the new steel bridge.

It will be noted that the labor on the timber deck of the new bridge cost only \$150, which is equivalent to 40 cts. per lin. ft. This is about two-thirds the cost of similar work given in our issue of April 10. In fact the whole cost of erection was correspondingly less in this bridge work, in spite of the fact that the daily wages averaged 15 per cent higher. A comparative study of this sort will frequently disclose unsuspected inefficiency of men and foremen.

We shall next consider the cost of erecting a steel plate lattice girder of 100 ft. span. This girder was erected by company forces, and it replaced a wooden bridge. The weight of the steel was 327, or 1,540 lbs. per lin. ft. It was erected by a force of 18 men 0 days, including 2 days spent in traveling, and the average

wage paid was \$3.18 per day, including the foremen in the average. The foremen's wages amounted to 13 per cent of the total wages paid, which was an unusually high percentage. The rate of wages were as follows:

General foreman	\$ 5.00	
Sub-foreman	3.50	
Drivers of rivets.....	3.25	
Heaters of rivets.....	3.00	
Buckrup of rivets.....	3.00	
Bridgemen	3.00	
Carpenters	2.75	
Stationary engineman	3.25	
<i>Time Traveling—</i>		
2 days at	\$5.00	\$ 10.00
2 days at	3.50	7.00
12 days at	3.25	39.00
18 days at	3.00	54.00
4 days at	2.75	11.00
38 days total at	\$3.18	\$121.00
<i>Rigging—</i>		
1 day at	\$5.00	\$ 5.00
1 day at	3.50	3.50
4 days at	3.50	13.00
6 days at	3.00	18.00
12 days total at	\$3.30	\$ 39.50
<i>Loading Tools—</i>		
2 days at	\$5.00	\$ 10.00
2 days at	3.50	7.00
5 days at	3.25	16.25
5 days at	3.00	15.00
14 days total at	\$3.45	\$ 48.25
<i>Steel Work—Erecting Girders—</i>		
1 day at	\$5.00	\$ 5.00
1 day at	3.50	3.50
4 days at	3.25	13.00
6 days at	3.00	18.00
12 days at	\$3.30	\$ 39.00
<i>Erecting Floor System—</i>		
1 day at	\$5.00	\$ 5.00
1 day at	3.50	3.50
10 days at	3.25	32.50
12 days at	3.00	36.00
24 days total at	\$3.21	\$ 77.00
<i>Riveting—</i>		
2 days at	\$5.00	\$ 10.00
3 days at	3.50	7.00
18 days at	3.25	58.50
20 days at	3.00	60.00
42 days total at	\$3.23	\$135.50
<i>Timber Deck—</i>		
6 days framing ties at.....	\$2.75	\$ 16.50
12 days laying floor at.....	2.75	33.00
18 days total at	\$2.75	\$ 49.50

Painting—

10 days at	\$3.25	\$ 32.50
10 days at	3.00	30.00
<hr/>		
20 days total at	\$6.12	\$ 62.50
<hr/>		
Total labor		\$672.75
Wear of tools		25.00
Coal		10.25
<hr/>		
Total		\$618.00

Summary—

		Per ton.
Traveling	\$121.00	\$1.40
Rigging	39.50	0.48
Loading tools	48.25	0.59
Steel work	252.00	3.08
Timber deck	49.50	0.60
Painting	62.50	0.76
Tools and coal	45.25	0.55
<hr/>		
Total	\$618.00	\$7.54

It will be noted that the cost of work on the timber deck was 49½ cts. per lin. ft.

The cost of building the false work is not included in the above estimate.

Cost of Erecting a Draw Bridge of 236-ft. Span.*—This single track railway bridge has a span of 236 ft., and a length of 239 ft. over all. Trusses are 16 ft. c. to c., and the depth of truss is uniform and 25 ft. c. to c. of chord pins. The center panel is 16 ft. and the remaining 10 panels are each 22 ft. The bridge is designed to be turned by hand only, and has a drum 22½ ft. x 4¾ ft. The bridge was designed for a live load of 3,200 lbs. per lin. ft.

The total weight of the metal is 433,300 lbs., distributed as follows:

	Lbs.
Trusses	205,60
Lateral bracing	20,000
Floor system	107,000

Turntable—

Drum (22½ ft. diam.)	21,400
Wheels (46)	18,200
Track	11,100
Rack	4,900
Tread pls.	5,200
Gearing and journal boxes	25,400
End lift	10,300
End supports	6,200
<hr/>	
Total ..	433,300

**Engineering-Contracting*, Aug. 21, 1907.

The itemized cost (to the contractor) of erection was as follows:

General Expense:

7.5 days, foreman at \$5.00.....	\$ 37.50
44 days, bridgemen, at \$3.00.....	132.00
34 days, laborers, at \$2.00.....	68.00
10 days, watchman, at \$2.00.....	20.00
3 days, blacksmith, at \$3.00.....	9.00
<hr/>	
\$8.5 Total labor, at \$2.67.....	\$266.50
3,000 ft. B. M. in traveler, at \$25.....	75.00
<hr/>	
Total	\$341.50

Thus \$341 includes the cost of erecting a derrick to unload the steel from cars, the labor of making and erecting traveler.

Erection of Steel Work:

19 days, foreman, at \$5.00.....	\$ 95.00
110 days, bridgemen, at \$3.00.....	330.00
80 days, riveters, at \$3.00.....	240.00
72 days, heaters and buckers, at \$2.00.....	144.00
84 days, laborers, at \$2.00.....	168.00
<hr/>	
366 Total labor, at \$2.65.....	\$ 969.00
80 days' rent of hoisting engine, at \$3.00.....	90.00
10 tons coal, at \$3.00.....	30.00
<hr/>	
Total	\$1,089.00

The engineman received the same wages as the bridgemen and was classed with them.

3 days, foreman, at \$5.00.....	\$ 15.00
9 days, bridgemen, at \$3.00.....	27.00
80 days, painters, at \$2.50.....	200.00
<hr/>	
92 days total labor.....	\$242.00
Total materials and labor.....	\$387.00

Timber Deck (17,000 ft. B. M.):

2 days, foreman, at \$5.00.....	\$10.00
26 days, carpenters, at \$2.75.....	71.50
3 days, laborers, at \$2.00.....	6.00
<hr/>	
31 days total labor, at \$2.90.....	\$92.50

It will be noted that the labor of framing and placing the timber deck (i. e., the ties, guard rails, etc.), cost \$5.60 per M., or 28 cts. per lin. ft. of bridge.

Since the bridge weighed 433,000 lbs., or 216.5 tons, the cost per ton for erection may be summarized as follows:

<i>General Expense:</i>		Per ton.
Labor	\$ 266.50	\$1.23
Material for traveler.....	75.00	0.35
<hr/>		
<i>Erecting Steel:</i>		
Labor	\$ 969.00	\$4.49
Rent of engine	90.00	0.42
Coal for engine.....	30.00	0.14

Painting:

Materials	\$ 35.00	\$0.44
Labor	242.00	1.11
Timber deck	92 50	0.42
Total	\$1,860.00	\$3.60

This work was done by a contractor who received \$12 per day for erecting the bridge. Practically no falsework was necessary, since the bridge was erected upon the "draw protection," which served as a falsework.

The bridge metal cost 4 cts. per lb. f. o. b. cars, ready for erection, and, since the contract price was 0.6 cts. for erection, the total was 4.6 cts. per lb. in place, or \$19,931 for the total superstructure, exclusive of the timber deck. This is equivalent to nearly \$85 per lin. ft. There were nearly 70 ft. B. M. per lin. ft. of timber deck (ties and guard rail), which cost \$20 per M., or \$1.40 per lin. ft. of bridge.

Cost of Erecting Pratt Truss Bridges.—A Pratt truss steel railway bridge, 130 ft. long, 14 ft. wide and 20 ft. high, was built to replace two Howe pony truss bridges, each 65 ft. long. The cost of this work was as follows:

Falsework, materials and labor.....	\$174.00
Removing falsework.....	100.00
Taking down two Howe truss bridges.....	145 00

Wages of common laborers were \$1.50, and of bridgemen \$2.50 a day.

It took a gang of 20 men 45 hrs. to erect a 200-ft. span Pratt truss highway bridge, of the combination type (wooden upper chord and posts and steel lower chord and diagonals), after the pile falsework was in place. The roadway was 16 ft. wide. A hoisting engine was used, and the posts were up-ended in pairs just as trestle bents are raised. A mast was used in raising the upper chord pieces. There was no upper falsework, nor was a traveler used.

Cost of Three-Plate Girder Bridges of Ten Spans.*—The data in this article relate to three plate girder (deck) bridges, on concrete abutments and piers, having pile foundations, built to replace existing timber bridges.

The first bridge consisted of three spans, one 30-ft. and two 75-ft. girder spans, having a total weight of 110 tons. The work was done by company forces, the details of cost being as follows:

Moving rigging from the last bridge—

1½ day, foreman, at \$3.40.....	\$ 1.70
2½ days, carpenters, at \$2.50.....	6.25
2 days, laborers, at \$2.25.....	4.50
1 day, stationary engineer, at \$3.....	3.00
	<hr/>
	\$15.45

Erecting portals for lowering the two 75-ft. girder spans—

1½ days at \$3.40.....	\$ 5.10
6 days at \$2.50.....	15.00
3 days at \$2.25.....	6.75
	<hr/>
	\$26.85

**Engineering-Contracting*, April 17, 1907.

1 day at \$3.40.....	\$ 3.40
5 days at \$2.50.....	12.50
2 days at \$2.25.....	4.50

\$20.40

Total labor\$787.87

This is equivalent to \$7.15 per ton, or \$4.35 per lin. ft. of span.

The cost per ton may be summarized as follows:

	Per ton.
General labor preparatory to erection, \$75.34.....	\$ 68
Painting inaccessible parts, \$42.75.....	.39
Placing girders, \$265.38.....	2.41
Riveting and mach. bolts, \$287.75.....	2.63
Timber deck work, \$114.65.....	1.04
Total	\$7.15

The timber deck work cost 64 cts. per lin. ft. of span. It will be noted that there were 4½ days of work train service costing \$112.50, or \$1.02 per ton. Deducting this, we have \$675 left, to be divided by 247 days' labor, which gives \$2.73 as the average wage paid. There

were 13 days of foreman's time, which amounted to \$44, or less than 7% of the 675.

The total cost of this bridge was:

Four concrete abutments and piers.....	\$ 7.950
Materials in superstructure.....	5.600
Labor erecting superstructure.....	788
False work.....	770
Engineering and inspection.....	500
Total	\$15.608

This is practically \$85 per lin. ft. of bridge, including abutments and piers. The falsework cost about \$4 per lin. ft. of bridge, or practically as much as the labor of erecting the spans.

It will be seen that the substructure cost more than the superstructure.

The second bridge was three 50-ft. plate girder spans, having total weight of 89 tons, on concrete abutments and piers. The cost of erecting by company forces was as follows.

Erecting false bents for lowering girders—

1 day, foreman, at \$3.40.....	\$ 2.40
4 days, carpenters, at \$2.50.....	10.00
10 days, laborers, at \$2.25.....	22.50
	\$35.90

Tearing up old bridge deck and pony bents—

0.8 day at \$3.40.....	\$ 2.72
5.6 days at \$2.50.....	14.00
5.6 days at \$2.25.....	12.60
	\$29.32

Placing and lowering girders from flat cars to piers—

1.2 days at \$3.40.....	\$ 4.08
8.4 days at \$2.50.....	21.00
8.4 days at \$2.25.....	18.90
	\$43.98

Framing ties—

1.5 days at \$3.40.....	\$ 5.10
14 days at \$2.50.....	35.00
	\$40.10

Putting ties in place and relaying track—

0.3 day at \$3.40.....	\$ 1.02
2.1 days at \$2.50.....	5.25
2.1 days at \$2.25.....	4.73
	\$11.00

Framing and placing guard rail—

1.5 days at \$3.40.....	\$ 5.10
8 days at \$2.50.....	20.00
6 days at \$2.25.....	13.50
	\$38.60

Tearing down false bents—

0.1 day at \$3.40.....	\$.34
0.7 day at \$2.50.....	1.75
0.7 day at \$2.25.....	1.57
	\$3.66

Work train on erection—

3 days at \$25.....	\$75.00
Total labor	\$277.56

This is equivalent to \$4.02 per ton, which may be summarized as follows:

	Per ton.
Erecting and tearing down false bents, \$39.56.....	\$.57
Tearing up old bridge deck and pony bents, \$29.32....	.42
Placing girders, \$43.98.....	.64
Timber deck work, \$89.70.....	1.30
Work train service, \$75....	1.09
Total	\$4.02

The labor cost of \$277.56 is equivalent to \$1.54 per lin. ft. of span. Tearing up old bridge deck and pony bents cost 16 cts. per lin. ft. The cost of the timber deck work was 50 cts. per lin. ft.

Exclusive of the train service, the total labor cost of erection was \$202, which, divided by the 82 days, is \$2.46 per day. The foreman worked 6½ days, receiving \$22, which is 11% of the labor cost, exclusive of train service, or 8%, including train service. As noted above, it took 1 foreman and 14 men 12 hours to place and lower the three girder spans. The first span took 5 hours; the second span, 4 hours; and the third span, 3 hours.

After erecting the new bridge, at the cost above given, it took the gang about a day additional to tear down the old wooden bridge, at a cost of \$44.

The total cost of this three-span girder bridge was:

Four abutments and piers.....	\$ 5,400
Materials in superstructure.....	3,600
Labor erecting superstructure.....	278
False work	650
Engineering and inspection.....	340
Total	\$10,268

This is \$55 per lin. ft. of bridge. The falsework cost \$3.50 per lin. ft.

The third bridge consisted of two 75-ft. girder spans and two 70-ft. girder spans (through bridge) on concrete abutments having pile foundations. The rates of wages paid were the same as on the first bridge, given above, and the cost per ton and per lin. ft. of bridge were about the same. The summary of the cost is as follows, the total weight of the four-span bridge being 197 tons:

	Per ton.
Removing old deck and placing girders, \$295.50.....	\$1.50
Putting in floor system, \$309.30.....	1.57
Riveting, \$482.80	2.40
Painting inaccessible parts, \$13.80.....	.07
Timber deck work, \$112.30.....	.57
Train service, \$275.80.....	1.40
Total	\$7.51

The timber deck work cost 40 cts. per lin. ft. of bridge. The total labor cost of erection was \$1,480, or \$5 per lin. ft. of bridge.

The total cost of the bridge was as follows:

Five piers and abutments.....	\$ 9,100
Materials in superstructure.....	10,700
Labor erecting superstructure.....	1,480
False work.....	1,320
Removing old bridge.....	520
Bunk house.....	60
Engineering and inspection.....	500
	<hr/>
	\$23,680

This is nearly \$80 per lin. ft. of bridge. The falsework cost \$4.40 per lin. ft.

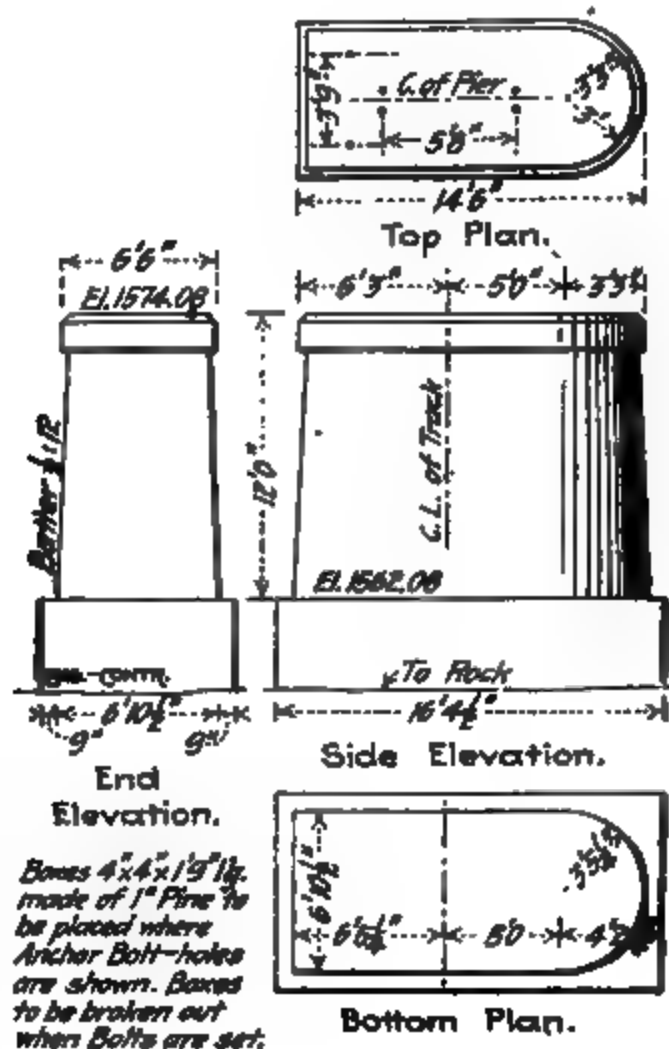

Fig. 1.—Bridge Pier.

Cost of a Plate Girder Railway Bridge with Concrete Piers.*—A deck plate girder railway bridge was constructed in the late Fall and in the Winter of 1905-6 to carry the Kansas City, Mexico & Orient Railway over the South Canadian River about 7 miles south of Woodward, in Dewey County, Oklahoma. The whole structure was built

*Engineering-Contracting, April 3, 1907.

by company forces and the following account of the methods of work and its cost has been prepared from information furnished by Mr. W. W. Colpitta, Assistant Chief Engineer, Kansas City, Mo.

Description of Bridge.—At the point of crossing, the river at ordinary high water is from 2,000 ft. to 4,000 ft. wide and drains approximately 1,000 square miles of territory consisting largely of rolling prairie. At low water the stream is shallow and easily fordable. The extreme rise at high water is about 10 ft., and at such periods the velocity of the current exceeds 6 miles per hour. The river bottom is quicksand and varies in depth to the underlying rock at the point of crossing from 12 to 60 ft.

After a careful study of the conditions respecting the elevations of high water, depth of foundation, nature of approaches and general character of the stream, a layout consisting of 1,000 ft. of 50-ft. deck plate girders at the north end where the rock is within 12 to 18

Fig. 2.—Cofferdam.

ft. of the surface, and of 1,000 ft. of pile trestle at the south end where the rock shelves off to a maximum depth of 60 ft., was decided upon as the most economical structure to fulfill the necessary requirements. The grade line was established to admit of replacing the pile trestle portion of the structure with 70 and 85 ft. deck plate girders at a later period. A concrete abutment and concrete piers were designed to carry the 50-ft. plate girders. Figure 1 shows the dimensions and details of the piers.

Methods of Construction.—The work was begun in the late fall, when an extreme rise in the river was unlikely to occur, and the very low cost of the structure was partially due to the fact that the work was little interfered with by high water. Telephone communication was established with Teloga, a point about 40 miles up the river, and a watchman stationed at that point observed and reported the stage of water at frequent intervals.

The concrete in the piers was of the following proportions: Iowa Sunflower Portland cement, one part; Arkansas River sand, furnished by Messrs. Luttgerding Bros., of Wichita, Kan., three parts; crushed limestone, passing a 2-in. ring, furnished by the Frazier Stone Co., of El Dorado, Kan., five parts. The concrete in the bridge seats was of the proportions, 1-2-4.

The bases of the piers and abutment were put down in open coffer dams, Fig. 2. The sheet piling, Fig. 3, for the first pier was driven with a light hammer, but this was found to be both slow and inefficient. The lower strata of sand proved to be more compact than had been anticipated, and, by this method, considerable difficulty was experienced in driving the sheet piles accurately and in preventing leaky joints. The balance of the sheet piling was driven with a 2-in. jet drawn to a 1-in. nozzle, and this method proved entirely satisfactory. The water was supplied by a 7 x 5 x 10-in. Gardner Duplex pump. The pile with the jet placed in the groove

Fig. 3.—Sheet Pile.

sank rapidly and accurately with the weight of two men clinging to a hanger slung over the top of the pile. When the pile had reached the bottom, it was struck several blows with a 12-lb. sledge to broom the point on the rock.

The piles were driven between 6 x 8-in. walings, firmly secured with wrought iron clamps, to prevent irregularities in the driving. Built up angles were made for the returns at the corners and jettied to rock in the ordinary manner. The actual time required to drive a coffer dam seldom exceeded ten hours.

It was originally the intention to build a form inside the coffer dam and to gather the water from leakages in a sump at one corner to be pumped out by a pulsometer, and to withdraw the sheet piling after the completion of the base. So little difficulty was experienced in preventing leakages that this plan was abandoned and the concrete was deposited against the sheet piling, which no attempt was made to recover. It was estimated that the loss of the sheet piling was more than offset by the time and expense necessary to have built an inside form.

The sand was pumped from the coffer dam by means of a No. 4 Morris centrifugal sand pump, having a 6-inch flexible suction

pipe and protected foot valve. The power to drive this pump was furnished by a traction engine, because of the ease with which it was supported on the river bottom at the pier sites. A sufficient amount of water was allowed to flow into the coffer dam through a small weir to keep the sand of the right consistency to be handled by the pump. As the excavation proceeded, the necessary shoring was placed in position. When the sand had been completely removed, the bottom of the sheet piling was grouted with cement mortar and the coffer dam kept dry by means of the pulsometer pump, while leaks were being stopped and other necessary work done, previous to depositing concrete. Except in cases where bad leaks or accidents occurred, the time required to remove the sand from a coffer dam averaged about eight hours. It was interesting to note

Fig. 4.—Forms for Pier.

the good state of preservation of tree trunks and limbs removed from the coffer dams. Leaves and twigs found in the compact sand near the rock were quite fresh and green.

The concrete was mixed with a No. 1 Smith mixer, having a batch capacity of about 9 cu. ft. The capacity of the machine was found to be ample to fill a coffer dam before the next ahead was completed. The mixer was placed in position on the slope of the embankment approach, with the main line track at its rear and facing a temporary material track. This temporary track turned out from the main line about 500 ft. beyond the mixer and extended diagonally down the embankment approach on a 3% grade and across the river bottom alongside the pier sites. The portion of the track in the river bottom was supported on bents of spliced ties, jettied to the rock, and wired to the coffer dam to avoid the danger of loss in case of high water. The sand and crushed rock were delivered by cars from the main line track, immediately above the mixer, and the cement was stored in a shanty at one side of the mixer. The concrete materials and machinery were, in this man-

ner, very conveniently located for rapid work and well above the high water line. The concrete was transported to the pier sites in improvised dump boxes, set on push cars. These dump boxes were hinged longitudinally and discharged directly into the coffer dams. The grade of the temporary track carried the push cars by gravity to the coffer dams and they were returned by teams, for which purpose a straw and brush road had been built paralleling the track. As the work progressed farther into the stream, more cars were added properly to balance the work. While the concrete in the base was still fresh, a number of steel reinforcing bars, 8 ft. in length, were set in place along each end to insure a good bond between the base and shaft.

Fig. 5.

In general, the work of putting in the bases was organized so that about the same time was required in filling a coffer dam with concrete, in excavating the sand from the next, and in driving the sheet piling for the third. These three operations were thus carried on simultaneously and, although interruptions in one part of the work or the other occurred frequently, the gangs were interchangeable and no appreciable loss was suffered, except in time, because of such delays.

In piers 19 and 20, where the rock was from 17 to 19 ft. below the surface, some difficulty was encountered due to the presence of fissures in the rock, from which it was necessary to remove the sand to fill with concrete. In such cases, the larger leaks were stopped as much as possible by driving sheet piles against the outside face of the coffer dam and into the fissures, and the smaller leaks by manure in canvass bags rammed into the openings.

Upon the completion of all bases, the frames (Figs. 4 and 5) for several shafts were set in position and the work of filling with concrete proceeded as in the case of the bases, except that a derrick

erected on a flat car and stationed at the pier was utilized to raise the dump boxes in depositing the concrete in the forms. As soon as the concrete in one shaft had set sufficiently to permit of it, the forms were removed and placed on the pier ahead. Four sets of forms were used for the shafts.

The girders, which were furnished by the American Bridge Co., were set in place with a derrick car of 20 tons' capacity.

Cost of Construction.—The following are the average prices paid for materials and labor:

Material.

Lumber for forms, etc., \$18.50 per M. ft., B. M.

Cement, Kansas Portland, \$1.50 per bbl.

Broken limestone, 46c per cu. yd., Kan.

Sand, Arkansas River, 15c per ton.

Labor:

General foreman, \$110 per month.

Assistant foreman, \$75 per month.

Timekeeper, \$60 per month.

Riveters, 35c per hour.

Blacksmith, 30c per hour.

Blacksmith assistant, 20c per hour.

Carpenters, 22½c and 25c per hour.

Enginemen, 25c per hour.

Firemen, 20c per hour.

Night watchman, 20c per hour.

Laborers, 17½c and 20c per hour.

Team (including driver), 40c per hour.

Note: The prices quoted for lumber, cement, limestone and sand are prices f. o. b., Louisiana, Iola, Kan., El Dorado, Kan., and Wichita, Kan.

The total and unit cost of constructing the concrete piers and abutments and of erecting the steel superstructure are given in the following tabulation. Altogether there was about 2,300 cu. yds. of concrete in the substructure, most of which, as stated above, was a 1-3-5 mixture.

Machinery and Supplies—

Concrete mixer, 20% of cost.....	\$ 152.10
Supplies, freight, hauling, setting up.....	505.04

Total	\$ 657.14
Centrifugal sand pump, 20% of cost.....	\$ 27.00
Supplies, freight, hauling, setting up.....	277.50
Rent of traction engine to operate.....	83.25

Total	\$ 387.75
Water pump and pipe, 20% of cost.....	\$ 29.00
Supplies, freight, hauling, setting up.....	177.32

Total	\$ 206.32
Pile driver engine, 20% of cost.....	\$ 100.00
Supplies, freight, hauling, setting up.....	243.65

Total	\$ 343.65
Grand total	\$1,594.86

Coffer Dams—

Materials, lumber and nails.....	\$1,285.26
Freight and train haul.....	306.33
Labor making piles.....	696.82
Labor driving piles.....	1,284.05
Total	\$3,672.46

The sheet piling took 63,500 ft. B. M. of lumber; the cost per 1,000 ft. B. M. for the sheet piling was then:

Materials, lumber and nails.....	\$ 20.08
Freight and haulage.....	4.82
Labor making piles.....	10.97
Labor driving piles.....	21.80
Total	\$ 67.67

Forms, Platforms and Runways—

Lumber, hardware, etc.....	\$ 224.59
Freight and train haul.....	40.29
Labor making, removing and placing.....	556.51
Total	\$ 821.30

Concrete Materials—

Cement, freight, unloading and storing.....	\$4,617.48
Sand, freight, unloading, etc.....	1,326.05
Broken stone, freight, unloading, etc.....	2,026.92
Total	\$7,980.45

This gives us for 2,300 cu. yds. of concrete a cost of \$3.47 per cu. yd. for materials, including freight, storage, and unloading charges of all kinds. A line on the proportion of the cost contributed by these latter items may be got by taking the prices of the materials f. o. b. at the places of production and assuming the proportions for a 1-3-5 concrete. According to tables in Gillette's "Handbook of Cost Data," a 1-3-5 broken stone concrete requires per cubic yard 1.13 bbls. cement, 0.48 cu. yd. sand and 0.80 cu. yd. broken stone. We have then:

1.13 bbls. cement, at \$1.50.....	\$1.69
0.48 cu. yd. sand, at 20c.....	.10
0.80 cu. yd. stone at 45c.....	.36
Total	\$2.15

This leaves a charge of \$1.32 per cubic yard of concrete for freight and handling materials. The cost of mixing concrete and placing it in the forms was \$3,490.87, or \$1.52 per cu. yd. We have then:

Cost of concrete materials per cu. yd.....	\$3.47
Cost mixing and placing concrete.....	1.52
Total	\$4.99

• *The miscellaneous expenses of the work comprised:*

Watchman, tools, telephone, etc.....	\$ 722.48
Shanties, furnishings, supplies, etc.....	829.04
Total	\$1,551.52

To this has to be added \$1,134.28, the cost of excavating the coffer dams. The total and unit costs of the different items of the concrete substructure work can now be summarized as follows:

Item.	Total.	Per cu. yd.
Machinery and supplies.....	\$ 1,594.86	\$.69
Coffer dams	3,672.49	1.60
Forms, etc.	821.30	.36
Concrete materials	7,980.45	3.47
Mixing and placing concrete....	3,490.87	1.53
Excavating coffer dams.....	1,134.28	.49
Miscellaneous	1,551.52	.67
Totals	\$20,245.74	\$8.80

The weight of steel in the plate girders was 694,479 lbs. The total and unit costs were as follows:

Item.	Total.	Per lb.
Steel girders.....	\$19,128.42	2.730 cts.
Freight on girders.....	1,365.60	0.215
Unloading and stacking.....	140.36	0.015
Total	\$20,634.37	2.96 cts.
Erecting girders	\$ 1,363.48	0.211 cts.
Derrick car, 20% of cost.....	127.10	0.009
Total	\$ 1,490.58	0.22 cts.
Grand total	3.18 cts.

The cost of the deck, material, freight, labor and painting was \$2,388.42, making the total cost of the superstructure \$24,613.37. Adding to this the cost of the substructure, as given above, we have \$44,759.11 as the total cost of the bridge. The cost per lineal foot, then, was:

For superstructure	\$24.51
For substructure	20.34
Total	\$44.75

Cost of Erecting Riveted Deck Girder Bridge.—A riveted deck girder bridge, 710 ft. long and 56 ft. high, consisting of seven 80-ft., one 60-ft. and three 30-ft. sections, was erected as described below. The bridge was to replace 525 ft. of timber trestle and two 103-ft. overhead Howe truss spans on a railway line over which 22 trains were moved between 7 a. m. and 6 p. m. Two travelers with tackle were used in the work. While the excavation was being done the falsework was put in, by trestling the two spans and cutting out a section 1 ft. long of the posts of the trestle part, and introducing an intermediate cap. a distance of 12 ft. below the rail to form lookouts for track for travelers. In this way the cost of the falsework was reduced and everything could be placed from the top, using one traveler for placing the pedestal stones the entire length, and for placing the posts on the return trip. After the posts had been placed the other traveler was erected in order to carry both ends of the girders. Owing to circumstances, the materials were unloaded 2,000 ft. from the bridge and were brought to it on push cars; that is, all except the girders, which were loaded on trucks

and moved with a locomotive. The girders were riveted together on the skids, the ties, tie plates, guard rail and rail placed upon them, and then loaded on trucks ready to be sent out. Jacks were placed under each end of the girders when they had been spotted over their place and they were raised clear of the trucks. The tackle was then attached, a strain taken, the trucks run out, and the jacks released, and they were swung clear. Owing to the height, the stringer-ties and guard rail had to be taken on deck. The bents were let down on the intermediate caps and the girders lowered into place by the means of the lines. It was possible to swing the girders either way, so that when they were within 6 ins. of their seat a small bar, pointed at each end, could be inserted to guide them into place. The first 80-ft. girder was placed in 2 hours and 22 minutes, and the second was placed in 1 hour and 38 minutes, while another girder was placed in 53 minutes. The following costs, incomplete though they are, may be of some value. The work was done some years ago when wages were lower than they now are. Cost of placing the 11 girders, together with the riveting, unloading steel, loading on trucks, engine attendance, etc., was \$1,255.49, or \$1.7683 per lin. ft.; cost of placing four rocker and three tower bents was \$570.04, or \$0.8003 per lin. ft.; total cost of superstructure, including falsework and traveler, was \$2,248.85, or \$3.1674 per lin. ft. The cost of riveting was as follows:

	Rivets.	Per rivet.
Riveting girder	8,028	\$0.0502
Riveting bents	480	0.1066
Riveting girders to post.....	264	0.1458

Cost of an Iron Bridge, including the Cost of Masonry Abutments.*—In this article we give the cost of erecting a 130-ft. span, supported by stone abutments and pier, at New Buffalo, Mich., for the Chicago & West Michigan Ry., the work being done in 1894.

The statement of the cost of the bridge to the railway company was as follows:

False work material (estimated).....	\$ 75.00
Ties, etc.	134.86
Iron span	5,568.00
1,050 cu. yds. excavation at \$0.26.....	262.50
425.4 cu. yds. stone (Grafton) at \$6.86.....	2,917.39
445 cu. yds. stone cut and laid at \$6.50.....	2,892.50
Filling behind abutment, laborers.	35.25
Filling behind abutments, engine work.....	5.10
Filling behind abutment, 10% above labor.....	4.04
Labor taking down old truss and erecting false work	176.76
Labor framing and placing ties and tie guard...	67.39
Labor taking down false work	27.00
Total cost	\$12,159.78

The actual cost of the stone masonry per cubic yard was \$13.05; of this sum \$6.50 was for cutting and setting and \$6.55 for the stone. The above cost of the stone is the cost to the railway

* *Engineering-Contracting*, February, 1906.

company at La Porte. Delivered at New Buffalo the stone would cost \$8.10 per cubic yard, making the actual cost of the masonry \$14.60 per cubic yard. The stone measured 425.4 cu. yds. in the block and made 444 cu. yds. in the wall, thus overrunning 18.6 cu. yds. A total of 51 cars of stone was used, the average weight per car being 34,500 lbs., the average number of cubic feet per car was 226; and the average weight per cubic foot was 144 lbs. These figures were based on the shipping weights of the cars. The stone was scabbled only, which accounts for the high weight per car.

The total cost of erecting the bridge was \$265.14, this including the labor for taking down the old truss, erecting false work, framing and placing ties and tie guard, and the labor for taking down the false work. The cost of erecting the 130 ft. span was therefore a trifle over \$2 per foot.

It will be noticed that the weight of the iron span is not given in the above statement of the cost of the work, nor is the number of men, the rate of wages or the time employed. The statement would have been much more complete had these details been obtainable.

Cost of a Plate Girder Bridge With Concrete Piers in Mexico.*—The following is rearranged from data originally published in the "Railway Age-Gazette": The bridge consists of 17 spans of 50 ft. deck plate girders carried on concrete piers and reinforced concrete piers and reinforced concrete abutments. The substructure is founded on solid rock ranging in depth below low water from zero on the west shore to 19 ft. on the east shore. The west abutment and succeeding 13 piers were carried to rock; the three remaining piers and the east abutment were set on piles driven to rock and cut off at low water level. The piers consist of bases 14 ft. 9 ins. x 7 ft. 9 ins. in dimensions and varying in height with the depth of foundation, and shafts 13 ft. 9 ins. x 6 ft. 9 ins. at the base, 12 ft. x 6 ft. at the top over coping and 28 ft. high. Each shaft contains about 848 cu. yds. of concrete. The spans between pier centers are 50 ft. 3 ins. The abutments are of reinforced concrete.

Two methods of construction were employed. The first method was used for the west abutment and the succeeding six piers. Operations were conducted from the river bed. The west abutment was above water level and was straightforward construction. For this six succeeding piers U. S. Steel Sheet Pile cofferdams were built and excavated; the base forms were set inside and concreted, and then the shaft forms were erected and concreted. A 60 x 120 x 4 ft. barge in the river carried a hoisting engine and stiff leg derrick. This derrick handled the forms and also a clam shell for excavating the cofferdams. A pile driver supported on heavy horses drove the sheeting. The concrete was mixed on the river bed by a $\frac{1}{2}$ cu. yd. Chicago Improved Cube mixer and taken to the work in dump buckets in push cars running on a track

**Engineering-Contracting*, Feb. 3, 1909.

which was extended from pier to pier. At the piers the buckets were raised and dumped by means of a mast and crosshead. When the pier was completed the girders were set by means of a 15-ton derrick car.

Work was conducted in the manner described from April 20, 1907, to May 1, 1908. This slow progress was due largely to the fact that the organization was such that one part of the work had to await the completion of another, no two operations being carried on at the same time. Furthermore the driving and pulling of the steel sheeting was a tedious process. It took from a week to ten days to drive the sheeting for one cofferdam, and in penetrating the cemented gravel the piles were often so battered and bent that it took as long or longer to pull as to drive them. The excavation of the cofferdam occupied about two days. It was to remedy this slow progress that the second method of construction was devised by Mr. W. W. Colpitts, Assistant Chief Engineer, who assumed personal charge of the work.

A second track was laid parallel to the main track as shown by Fig. 6. To support this second track 20-ft. guard rail timbers were inserted between each pair of main track ties and secured with hook bolts to the girder flanges. On the overhanging ends of these timbers two lines of 3 x 12-in. planks, on 5-ft. centers, were laid to carry the second track rails. The concrete mixed was removed from the river bed and placed on the west bank as shown by Fig. 6; the second track led directly to and from the mixer. A siding was also laid to the mixer for the sand and gravel cars, which were loaded at a nearby cutting. Water was pumped to the mixer from the river as shown by Fig. 6.

Fig. 6.—Plant Layout.

Leading from Main Line for Second & Gravel

The second track was extended from pier to pier as fast as the main track was completed, so that the derrick car could be run out on the second track to a position alongside the last completed pier. The derrick car boom was lengthened about 25 ft. by splicing and trussed with wire cables to sustain a load of 4 tons at its outer end. From the boom a 66-ft. extension of the second track was suspended by cables at the boom and at mid-length; the inner end of the extension track was supported by a bent on the pier. The arrangement of the extension track is made above by Fig. 6; as will be seen the concrete could come from the mixer by car to directly over the pier. When a pier had been concreted the extension track was set one side and detached and the derrick was available for erecting the plate girders.

Fig. 7.—Concrete Bucket.

For depositing concrete below water, a bucket was devised to operate with a single line, as illustrated in Fig. 7. It was built of a 3-ft. section of 36 in. corrugated iron culvert pipe, having a capacity of $\frac{1}{2}$ cu. yd. In the bottom, which was of wood, was a clap valve 8 ins. square opening upward. A 1-in iron trunnion set 6 ins. off center was secured to the bottom. A bale with chain hooks at its extremities was attached to the pile line of the derrick car which was led through a block at the end of the boom directly over the center of the pier. To the top of the bale was pivoted a counter-weighted trip engaging a lip on the side of the

bucket. The bucket was carried on a push car and the mixer discharged directly into it. It was then run out to the end of the extension, the hooks of the bale slipped over the trunnions, the trip caught on the lip, the bucket raised, and the car pushed from under it. The bucket was then lowered and upon its weight being taken on the bottom the trip automatically released. As the bucket was slowly raised from the bottom and upset, the valve in the bottom opened and the concrete poured out without disturbance; its construction being such that it discharged toward the lowest point. Three buckets were used, one being dumped while two others were on their way to and from the mixer; the loaded car using the second track, the empty car returning on the main track.

The concrete for the shafts was carried in dump boxes on push cars, Fig. 8. The forms were securely wired to prevent distortion from the falling concrete and baffle boards were used to distribute the concrete uniformly.

It was found that detachable cast steel teeth on the lips of the clam shell greatly increased the daily capacity of the dredge and

Fig. 8.—Concrete Car.

this fact suggested the advisability of doing away entirely with the steel sheet piling which had proven both expensive and slow. The greatest depth to rock was 19 ft. below the low water surface and was practically level over the area of a pier. It was decided to sink open wooden cofferdams, first dredging as deep as practicable in the open water at the pier site, the limit of which proved to be about 12 ft. In the meantime, the timber for the cofferdams was being framed on the bank. They were built as follows: The three bottom courses were composed of condemned bridge stringers, the lower one having a 45° cutting edge, unshod. Above the stringers the sides were composed of 3x12-in. plank, spiked to corner posts and studs.

During construction the cofferdam was supported on a raft also composed of condemned bridge stringers. The raft was built with an open bay, about 1 ft. larger on all sides than the cofferdam.

Across the center of the opening was stretched a heavy telegraph wire supporting the ends of four planks, the other ends resting on the raft. The lower courses of timbers of the cofferdam were then set in position on these planks and drift-bolted together. The position of the cofferdam on the planks was such that only a small percentage of its weight came upon the wire. The two other courses of stringers were then laid and bolted to these, after which the 3-in. planks comprising the balance of the sides of cofferdam were spiked to the corner posts and studs. When completed, the wire was cut and the cofferdam launched into the water below, which, as stated above, had previously been dredged to a depth of about 12 ft. It was then guyed to its exact position and held level by lines from the boom of the barge derrick. Four posts or legs, with the lower ends resting on the bottom of the excavation, were spiked to the outside corners and all the guys removed, allowing the cofferdam to rest entirely upon these legs. To make provision for weighing the cofferdam while being sunk, stringers were placed across its ends and on the portions projecting beyond the sides, a floor of other stringers was laid and boxed up to a height sufficient to carry a load of about 75 tons of gravel each. The dredging operations were then begun and the material taken from the interior of the cofferdam placed in the boxes until they were filled. When the dredging had continued to a point where the bearing was uniform on the cutting edge of the bottom, the legs detached themselves from the sides and floated to the surface.

By carefully sounding the bottom and loading the boxes uniformly as the dredging proceeded, the cofferdam sank uniformly to the rock. The load was not removed from the boxes until the concrete had been placed, when by cutting the wires supporting the sides the gravel dropped into the water. The cofferdam was prevented from bulging when the concrete was being deposited, by means of a wire cable strung around the top and wedged taut at each of the studs. The derrick car was not removed from its position supporting the extension track until the concrete in both the base and shaft had been placed. The pile line of the derrick car was, therefore, available in removing the form on the shaft of the pier behind and erecting it on the recently completed base. The operation of filling it with concrete was then begun. While the work of placing the concrete in the base, erecting the form for the shaft, filling it and setting the girders was going on, the barge was employed in dredging for and sinking the next cofferdam, and in this manner the work proceeded until the 13th pier was completed.

The piles in the foundations of the three piers on the east bank of the river were driven with rail leads suspended loosely from the boom of the stiff-legged derrick, which had been removed and placed on skids on the bank. The forms were set and filled in the manner described.

The method of building the west abutment was as follows: Upon the completion of the excavation, the form was built up to a point

8 ft. above the bottom of the overhang. The piles were then driven and the back-filling completed up to the level to which the form had been built and care taken to tamp the filling solidly under the form for the overhang. The form was then filled with concrete to the top and the overhanging slab, which was 3 ft. thick, reinforced with steel to enable it to support the load of green concrete that would later come upon it. The form for the upper portion was then completed and the whole filled with concrete up to the bridge seat in two days' run. The west abutment was completed and the last span set on August 27, 1908, an average, after May 1, of one pier and span about every nine working days.

The statement of cost will be especially interesting to those who are familiar with conditions in the Republic of Mexico. Generally speaking, machinery, materials and supplies of all kinds are much more costly than in the United States, but this disadvantage is partly offset by cheap labor. The scale of wages (in U. S. currency) that prevailed on the work are given below:

The cost of materials delivered at the work was as follows:

General foreman	\$150.00 per month
Sub-foremen	4.00 per day
Hoisting engineers	4.00 per day
Firemen	1.50 per day
Carpenters	1.50 per day
Blacksmiths	2.00 per day
Laborers (peons)75 per day
Cement, per bbl.	\$ 3.72
For lumber, per M. ft. B. M.	23.33
Bridge timber, per M. ft. B. M.	36.65
Reinforcement, per ton.	79.20
Steel sheeting, per ton.	54.15
Bridge steel, per ton.	69.98

In the statement below a proportion of the cost of all machinery and tools is charged against the bridge, depending upon their condition and availability for future work.

Abutments.

(Contain 586.2 cu. yds. concrete.)

Material.	Total.	Per cu. yd.
Cement, 694.4 bbls., at \$3.73.	\$2,590.11	\$4.42
Sand, 263 cu. yds., at \$0.50 1/2.	132.81	0.23
Gravel, 526 cu. yds., at \$0.50 1/2.	265.62	0.45
Lumber, 22,232 ft., B. M., \$23.33.	518.66	0.88
Piles, 240 lin. ft. at \$0.22.	52.80	0.09
Reinforcement, 41,730 lbs., at \$3.96.	1,632.51	2.79
Machinery, proportionate cost.	59.21	0.10
Wire and nails.	101.50	0.18
Lubricating oil	6.50	0.01
Fuel	102.00	0.18
Total material	\$5,468.72	\$9.33

Labor.

Total cost of superstructure.....\$25,814.43

Total cost of bridge.....\$59,040.38

Cost of Erecting a Draw Bridge of 236-ft. Span.*—This bridge has a span of 236 ft., and a length of 239 ft. over all. Trusses are 16 ft. c. to c., and the depth of truss is uniform and 25 ft. c. to c. of chord pins. The center panel is 16 ft. and the remaining 10 panels are each 22 ft. The bridge is designed to be turned by hand only, and has a drum 22½ ft. x 4½ ft. The bridge was designed for a live load of 3,800 lbs. per lin. ft.

The total weight of the metal is 433,300 lbs., distributed as follows:

	Lbs.
Trusses	205,600
Lateral bracing	20,000
Floor system	107,000
Turntable—	
Drum (22½ ft. diam.)....	21,400
Wheels (46)	16,200
Track	11,100
Rack	4,900
Tread pla.	5,200
Gearing and journal boxes....	25,400
End lift	10,200
End supports	6,300
Total	433,300

The itemized cost (to the contractor) of erection was as follows:

General Expense—

7.5 days, foreman at \$5.00.....	\$ 37.50
44 days, bridgemen, at \$3.00.....	132.00
34 days, laborers, at \$2.00.....	68.00
10 days, watchman, at \$2.00.....	20.00
3 days, blacksmith, at \$3.00.....	9.00
95.5 Total labor, at \$2.67.....	\$268.50
3,000 ft. B. M. in traveler at \$25.....	75.00
Total	\$341.50

This \$341 includes the cost of erecting a derrick to unload the steel from cars, the labor of making and erecting traveler.

Erection of Steel Work—

19 days, foreman, at \$5.00.....	\$ 95.00
110 days, bridgemen, at \$3.00.....	330.00
80 days, riveters, at \$3.00.....	240.00
73 days, heaters and buckers, at \$2.00.....	146.00
84 days, laborers, at \$2.00.....	168.00
366. Total laborers, at \$2.65.....	\$ 969.00
30 days' rent of hoisting engine, at \$3.00.....	90.00
10 tons coal, at \$3.00.....	30.00
Total	\$1,089.00

**Engineering-Contracting*, May 29, 1907.

The engineman received the same wages as the bridgemen and was classed with them.

3 days, foreman, at \$5.00.....	\$ 15.00
9 days, bridgemen, at \$3.00.....	27.00
80 days, painters, at \$2.50.....	200.00
<hr/>	
92 days total labor	\$242.00
Total materials and labor	\$337.00

Timber Deck (17,000 ft. B. M.)—

3 days, foreman, at \$5.00.....	\$15.00
26 days, carpenters, at \$2.75.....	71.50
3 days, laborers, at \$2.00.....	6.00
<hr/>	
32 days total labor at \$2.90.....	\$92.50

It will be noted that the labor of framing and placing the timber deck (i. e., the ties, guard rail, etc.) cost \$5.50 per M, or 38 cts. per lin. ft. of bridge.

There is clearly some error in the amount of red lead and oil above given. Since the bridge weighed 433,000 lbs., or 216.5 tons, the cost per ton for erection may be summarized as follows

<i>General Expense—</i>		Per ton.
Labor	\$ 266.50	\$1.23
Material for traveler	75.00	0.35
<i>Erecting Steel—</i>		
Labor	\$ 969.00	\$4.49
Rent of engine	90.00	0.42
Coal for engine	30.00	0.14
<i>Painting—</i>		
Materials	\$ 95.00	\$0.44
Labor	242.00	1.11
Timber deck	92.50	0.42
<hr/>		<hr/>
Total	\$1,860.00	\$8.60

This work was done by a contractor who received \$12 per ton for erecting the bridge. Practically no falsework was necessary, since the bridge was erected upon the "draw protection," which served as a falsework.

The bridge metal cost 4 cts. per lb. f. o. b. cars, ready for erection, and, since the contract price was 0.6 cts. for erection, the total was 4.6 cts. per lb. in place, or \$19,931 for the total superstructure, exclusive of the timber deck. This is equivalent to nearly \$85 per lin. ft. There were nearly 70 ft. B. M. per lin. ft. of timber deck (ties and guard rail), which cost \$20 per M, or \$1.40 per lin. ft. of bridge.

Cost of Howe Truss Bridges, Cross-References.—In the section on Timberwork will be found other data on Howe truss bridges.

Cost of a 150-ft. Howe Truss Bridge.—The following data were published in *Engineering-Contracting*, June 26, 1907. While the old-fashioned Howe truss railway bridge is no longer built in the eastern part of America, it is still to be found in the West, and is likely to remain in use, here and there, for many years to come. Practically nothing has ever found its way into print as to

the cost of erecting Howe truss bridges, hence the following data should be of value to many of our readers.

A railway Howe truss through span bridge of 150 ft. span, was erected by company forces at the following cost:

Loading Bridge Material—

2 days, foreman, at	\$3.00	\$ 6.00
18 days, carpenter, at	2.50	45.00
12 days, helper, at	2.00	24.00
32 days. Total	\$2.34	\$75.00

Loading Hoisting Engine—

0.5 day, pile driver engr., at	\$3.00	\$ 1.50
0.15 day, carpenter, at	2.50	3.75
0.5 day, helper, at	2.00	1.00
2.5 days. Total	\$2.50	\$ 6.25

Loading Pile Driver—

1 day, carpenter	\$2.50	\$ 2.50
1 day, helper	2.00	2.00
2 days. Total	\$2.25	\$ 4.50

Fitting Up Pile Driver—

13.5 days, carpenter	\$2.50	\$33.75
3.5 days, helper	2.00	7.00
17 days. Total	\$2.40	\$40.75

Driving Pile Falsework—

1 day, foreman	\$3.00	\$ 3.00
1 day, engineer	3.00	3.00
8 days, carpenter	2.50	20.00
5 days, helper	2.00	10.00
15 days. Total	\$2.40	\$36.00

Framing and Erecting Bridge—

30 days, foreman	\$3.00	\$ 90.00
22 days, engineer	3.00	66.00
236 days, carpenter	2.50	590.00
260 days, helper	2.00	520.00
548 days. Total	\$2.30	\$1,266.00

Train Service—

2 days, conductor	\$3.50	\$ 7.00
4 days, brakeman	2.50	10.00
2 days, locomotive and crew	25.00	50.00
Total		\$67.00

Miscellaneous—

11 tons coal for hoisting engine, at \$3	\$ 33.00
Repairs to hoisting engine	24.00
Tools, etc.	135.00
Total	\$192.00

Bridge Materials—

88,800 ft. B. M. timber, at \$15	\$1,332.00
44,800 lbs. wrought iron, at 2½ cts.	1,120.00
40,000 lbs. cast iron, at 1.8 cts.	720.00
Total	\$3,172.00

Falsework Material—

1,120 lin. ft. piles (28 piles, 40 ft.). at 8 cts.....	\$ 89.60
30,000 ft. B. M., second hand, at \$8.00.....	240.00
500 lbs. iron, at 2½ cts.....	12.50

Total\$242.10

Pile Abutments Material—

1,600 lin. ft. piles (40 piles, 40 ft.). at 8 cts.....	\$128.00
1,700 lbs. iron, at 2½ cts.....	42.50
7,600 ft. B. M., at \$15.....	114.00

Total\$284.50

Pile Abutment Labor—

5 days, foreman, at.....	\$3.00	\$ 15.00
5 days, engineman, at.....	3.00	15.00
36 days, carpenter, at.....	2.50	90.00
30 days, helper, at.....	2.00	60.00
76 days. Total.....	\$2.37	\$180.00

SUMMARY.**Labor—**

32 days, loading material, at.....	\$2.34	\$ 75.00
2¼ days, loading engine.....	2.60	6.25

15 days, driving falsework.....	2.40	36.00
348 days, erecting bridge.....	2.30	1,266.00
2 days, train service.....	...	67.00
76 days, building pile abutments.....	2.37	180.00
Miscellaneous supplies.....	...	192.00

Total labor and supplies.....\$1,867.50

Materials—

Falsework material.....	\$ 242.10
Abutment material.....	284.50
Bridge material —	
88,800 ft. B. M., at \$15.....	1,332.00
44,800 lbs. wrought iron, 2¼ cts.....	1,120.00
40,000 lbs. cast iron, 1.8 cts.....	720.00

Total material\$3,698.60

Total labor and material.....\$5,566.10

The abutments were not protected by cribs, nor is any riprap included in the above cost. In subsequent issues we shall give costs of abutments protected by cribs and riprap.

The cost per lineal foot of bridge was as follows:

Labor—

		Per lin. ft.
General labor, loading materials, etc....	\$ 182.50	\$ 1.08
Erecting bridge.....	1,266.00	8.44
Train service.....	67.00	0.45
Building pile abutments.....	180.00	1.20
Miscellaneous supplies.....	192.00	1.28
Total labor.....		\$12.45

Material—

Falsework	\$ 242.10	\$ 1.61
Abutment	284.50	1.90
Bridge	3,172.00	21.16

Total material\$24.66

Total labor and material.....\$37.11

It will be noted that the cost of fitting up the pile driver (\$40.75) was excessive; but, on the other hand, the cost of driving the pile falsework (\$36) was low.

The cost of framing and erecting the bridge (\$1,266) includes the cost of erecting the upper falsework.

The labor on the pile abutments (\$180) was high, considering there were no cribs.

Cost of Two Howe Truss Bridges of 120-ft. and 130-ft. Span, including Falsework and Pile Abutments.*—The following data relate to a through Howe truss bridge 130 ft. long over all, for which a contract was let for the labor of erecting the bridge. The contractor paid bridge carpenters \$2.75 a day and helpers \$2.00

The bridge was designed for a live load of engine and tender weighing 112 tons, followed by a train of 3,000 lbs. per lin. ft. The dead load was 1,650 lbs. per lin. ft.

The cost of the bridge to the railway company was as follows:

Falsework—

840 lin. ft. piles (20 piles) delivered at 8 cts....	\$ 67.20
840 lin. ft. piles driven at 12 cts.....	100.80
24,000 ft. B. M. timber delivered at \$15.....	360.00
24,000 ft. B. M. timber framed and erected at \$7.50	180.00
400 lbs. iron at 25 cts.....	10.00

Total, \$5.52 per lin. ft. bridge.....\$ 718.00

Pile Abutments—

1,400 lin. ft. piles (40 piles, 35 ft.) delivered at 8 cts.	\$ 112.00
1,400 lin. ft. piles, driven, 12 cts.....	168.00
1,700 lbs. iron, 2.5 cts.....	42.50
7,600 ft. B. M. timber delivered, \$15.....	114.00
7,600 ft. B. M. framed and erected, \$7.50.....	57.00

Total for two abutments.....\$ 493.50

Howe Truss Bridge—

29,000 lbs. cast iron, at 2 cts.....	\$ 580.00
34,000 lbs. wrought iron, 2½ cts.....	850.00
71,700 ft. B. M. timber, at \$15.....	1,075.00
130 lin. ft. bridge framed and erected, at \$7.50...	975.00

Total\$3,480.00

Train service..... 50.00

Total\$3,530.00

Summary—

Falsework, materials.....	\$ 437.20
Falsework, labor (by contract).....	280.80
Pile abutments, materials.....	268.50
Pile abutments, labor.....	225.00
Howe truss bridge, materials.....	2,515.00
Howe truss bridge, labor.....	975.00
Train service.....	50.00

Grand total, 130 lin. ft., at \$36.50.....\$4,751.50

It will be noted that there was no crib, crib filling or riprap protection for the abutments. It would not be excessive to add 400 cu. yds. of riprap and rock in cribs, at \$1.50 per cu. yd., and 24,000 ft.

**Engineering-Contracting*, July 3, 1907.

B. M. (or 2,000 lin. ft.) of hewed timber for two cribs to protect the abutments. A common contract price in the West is 15 cts. per lin. ft. of crib timber in place.

The full cost of the timber for the falsework in this bridge is charged against the bridge, but, since most of it possesses a salvage value, not to exceed half the cost of the timber (half of \$250) should be so charged.

It will be noted that the contract price of framing and erecting the bridge was \$950, which is equivalent to about \$14 per M. ft. B. M. in the bridge, exclusive of the falsework. The falsework cost \$718, which, if added to the \$975, gives a cost of \$1,693, or \$18 per lin. ft. of bridge.

The piles for the falsework were driven in bents about 11 ft. apart, two piles to the bent. While this is a sufficient support for the dead load of a Howe truss bridge, it is evidently insufficient to support any trainload during construction. In rebuilding an old bridge, without interruption to traffic, it is evident that the falsework would be much more expensive than in this case, which is typical of new construction rather than of reconstruction.

The following costs relate to a Howe truss bridge 120 ft. long, and the remarks concerning the 130-ft. bridge apply also to this one:

Falsework—

540 lin. ft. piles (18 piles) delivered at 8 cts..	\$ 43.20
540 lin. ft. piles driven, 12 cts.....	64.80
28,000 ft. B. M. at \$15.....	420.00
28,000 ft. B. M. framed and erected, \$7.50.....	210.00
400 lbs. iron, 2.5 cts.....	10.00
Total at \$6.23 per lin. ft. bridge.....	\$ 748.00

Pile Abutments—

Same as for previous bridge.....	\$ 493.50
----------------------------------	-----------

Howe Truss Bridge—

63,000 ft. B. M. at \$15.....	\$ 945.00
28,400 lbs. wrought iron at 2.5 cts.....	710.00
25,400 lbs. cast iron at 2 cts.....	508.00
120 lin. ft. framed and erected, \$7.50.....	900.00

Total\$3,063.00

Train service..... 50.00

Summary—

Falsework, materials.....	\$ 463.20
Falsework, labor (by contract).....	274.80
Pile abutment, materials.....	268.50
Pile abutment, labor.....	225.00
Howe truss bridge, materials.....	2,163.00
Howe truss bridge, labor.....	900.00
Train service	50.00

Grand total, at \$36.20 per lin. ft.....\$4,344.50

As previously stated, no protection cribs, rock filling, or riprap are included in the cost of the abutments.

Cost of Constructing Six Crib Piers, Three Howe Truss Spans and One Steel Draw Span.*—Crib piers for railway and highway bridges possess the great merit of making it unnecessary to build coffer

**Engineering-Contracting*, July 24, 1907.

dams, and, on this account, have always been popular with Western engineers. During recent years, however, concrete piers, built within coffer dams, have become more common than crib piers. Nevertheless, there are many places where the crib pier is still the most economic pier that can be designed.

The bridge to be described in this article consists of three Howe truss spans of 150-ft. each, and a steel draw span almost 100-ft. long. It crosses a Washington river near its mouth, where the tidal currents cause a daily rise and fall of several feet. The river is 19 ft. deep at extreme low tide, and the top of the piers is 40-ft. above the river bed.

With the exception of the pivot pier, which will be described separately, the piers were crib piers resting on piles. A description of the construction of one of these five piers will serve for the rest.

Crib Pier.—Each pier is supported by 52 piles driven 3 ft. c. to c. to a depth of 30 ft. Piles 60 ft. long were necessary, due to the depth of the water at high tide, and were sawed off 7 ft. above the bottom of the river, or 12 ft. below extreme low water. The driving was very hard, the bottom being of sand in which the average penetration of the pile was only 2 ins. under the blow of a 2,200-lb. hammer falling freely 20 ft. For sawing off the piles, a circular saw on a 40 ft. vertical shaft was used. The shaft was rotated by an engine mounted on a carriage movable in any direction on two tracks at right angles to each other, one track being above the other.

While the piles were being driven for a pier, the crib was constructed. Each crib consisted of a bottom, or floor, made of three solid courses of 12 x 12-in. timbers drift-bolted together, and on top of this bottom was built the crib proper. The bottom was built on shore and then launched. Then the crib was built of 12 x 12's log-house fashion, on top of the "bottom" until it reached a height of 12 ft. The crib was then floated over the rest of foundation piles, and arrangements made to lower it upon the piles. To insure a steady and even lowering of the crib, without risk of capsizing, it was necessary to lower the crib by means of blocks and tackle fastened to two bents of guide piles, one bent on each side of the crib. Rock was dumped into the crib, and it was sunk until it rested on the piles. This left the upper course of timber above the level of low water, and in readiness to continue the building up of the crib to the desired height. The cribs were designed so that the load of the bridge came directly upon the rock filling in the crib, the intention being to build masonry upon the rock fill after the crib timbers above the water level have rotted out.

In this connection it is interesting to note that the crib timbers were compressed nearly 1-16 in. per ft. of height, after the load came upon the piers. Part of this compression was doubtless due to shrinkage of the timber upon drying.

We would offer a suggestion as to a possible improvement in this form of crib pier construction. Let the foundation piles and the crib be built, in the manner above described, up to the low water

1. But from that level to the top of the pier, substitute rein-

forced concrete "timbers" in place of wood. These concrete "timbers" could be cast on shore, and made so as to interlock, forming a solid and durable outside wall. Loose rock filling and gravel could then be deposited inside this wall, thus giving the necessary stability to withstand the impact of ice and drift. A pier of this sort would be far cheaper than a solid masonry pier, but would possess sufficient stability and a durability equal to that of solid masonry. In pier building, it should be remembered, the engineer seeks to secure a mass that will resist impacts rather than a monolith of great strength.

Returning now to the methods used in this crib pier construction, one feature is worthy of particular note. A crib having a height two or three times greater than its width is very "cranky" when floating in the water. It tends to turn over, and this tendency is made serious where the tides are rising and falling. It was necessary to have one man in constant attendance day and night, tightening or loosening the guy-lines with the changes of water level.

Before placing the crib pier over the piles, riprap was deposited between them, and leveled off by a diver. After the crib pier was in place, riprap was piled all around the pier to a depth of 6 ft. above the river bottom.

The Pivot Pier—This pier differed from the piers just described in that it was a stone masonry pier resting on a timber grillage on top of piles. There were 121 piles, driven 3 ft. c. to c., forming a square 32 ft. on a side. The piles were sawed off only 18 ins. above the river bottom.

Sawing them off so close to the bottom was a mistake, for it entailed a great deal of trouble in placing the grillage upon the piles. This was due to the fact that dirt lodged upon the tops of the piles after they were sawed off, making it necessary for a diver to clean the piles off. The driving of the piles 3 ft. c. to c. caused the bottom to rise 6 to 12 ins. Then the eddies formed by the projecting pile heads and by the draw protection caused the floating sediment in the river to deposit around and on top of the piles. To add to the difficulty, the contractor had unfortunately deposited some of the riprap immediately after driving the piles, and many of the stones had lodged on top of the piles.

In this connection we recall a similar experience arising from the deposition of sand around the piles while they were being sawed off, dulling the teeth of the saw and adding greatly to the expense of cutting off the piles. The eddy caused by the piles of the draw protection was largely accountable for the trouble. Finally a V-shaped wing dam of boards was built in the draw protection immediately above the site of the pier, and it served to divert the stream of sand and gravel that is constantly rolling along the bottom of a swiftly flowing river.

The lesson learned by such experiences is simple: Do not cut off piles less than 2 ft. above the bottom of a river, unless there is some excellent reason for so doing.

The grillage built for this pivot pier was 33 ft. square and 15 ft. high, made of 12 x 12-in. timbers laid solid and drift-bolted together, except in the three upper courses where the timbers were laid 2 ft. apart, and the space filled with concrete.

At the bottom of the grillage, two timbers in each course projected beyond the others, so that guy lines could be fastened to them, by which the pier was kept balanced during construction while floating on the rising and falling tides. The guy lines were fastened to two pile bents, one on each side of the pier, which, together with the pile bents of the draw protection, formed a square enclosure in which the pier was guided to the bottom.

Of course the grillage sank under the weight of the masonry which was built on top of it. This masonry was laid inside on "open caisson" built on top of the grillage, the "caisson" being octagonal in shape, made of 3-in. plank, and 16 ft. high. The plank was beveled on the outer edges to provide caulking seams. Two small gates were provided in the "caisson," so that, when the pier had set properly on the piles at low tide, water could be let into the "caisson" and left there until the pier was finished. Then the gates were again closed, the water pumped out, and the masonry was painted.

Cost of the Piers.—The labor cost records were not kept in as great detail as one might wish, yet they possess considerable value. The quantities of materials and contract prices, however, will serve as an excellent guide, and are as follows:

3,120 lin. ft. piles (52) delivered at...	\$ 0.08	\$ 249.60
3,120 lin. ft. piles driven at.....	0.20	624.00
54,000 ft. B. M. delivered at.....	15.00	810.00
54,000 ft. B. M. framed and placed...	11.00	594.00
4,000 lbs. iron at.....	0.03	120.00
8 guide piles delivered at.....	3.00	24.00
4,000 ft. B. M. falsework at.....	15.00	60.00
190 cu. yds. rock (crib fill).....	2.00	380.00
580 cu. yds. riprap at.....	2.00	1,060.00
5 cu. yds. concrete at.....	8.00	40.00
Total		\$3,961.60

This is equivalent to \$100 per lin. ft. of height of pier, since the piers were 40 ft. high above the bed of the river.

Cost of Pivot Pier.

7,260 lin. ft. piles (121) delivered at...	\$8.08	\$ 440.30
7,200 lin. ft. pile driven at.....	0.20	1,440.00
162,800 ft. B. M. delivered at.....	15.00	2,442.00
162,800 ft. B. M. placed at.....	8.00	1,302.40
7,200 lbs. iron at.....	0.03	216.00
18 guide piles at.....	3.00	48.00
13,200 ft. B. M. falsework at.....	15.00	198.00
318 cu. yds. masonry at.....	15.00	4,770.00
570 cu. yds. riprap at.....	2.00	1,140.00
Total		\$12,009.20

This is equivalent to \$300 per lin. ft. of height of pier.

The contract price for driving the piles, 20 cts. per lin. ft., was high, considering the length of the pile, for it amounted to \$13 per

piles. But the driving was very hard, and the price for driving included cutting off the piles below water. It required 26 days to drive the 121 piles in the pivot pier and 10 days more to cut them off. Had a water jet been used the driving would have cost much less. The average rate and wages paid by the contractor for the pile driver crew was \$2.50 per day. If a crew of 6 men, a pile driver engineer and a foreman were required, the wages and fuel amounted to \$25 a day. Hence if 5 piles were driven per day the cost was \$5 a pile. Since 12 piles were sawed off per day the cost of sawing was more than \$2 per pile. No detailed records of the actual cost to the contractor are available further than that it required 3,800 days' labor at \$2.50, or \$9,500, to drive the piles, frame and place the timber, place the crib, fill the riprap for all the piers and lay the masonry. The stone for the masonry was delivered cut ready to lay. The riprap was delivered on scows and measured on the scows before placing.

The Howe Truss Spans.—Three Howe truss spans, each 150 ft. long, and one steel draw span, 293 ft. long, were built as follows:

These Howe truss bridges were erected on a pile falsework, each span having six bents of three 60-ft. piles to a bent. The outside piles of each bent were drawn in 4 ft. at the top and well braced to withstand the action of the deep swift river.

To protect the falsework against drift wood a temporary log boom was placed on the upstream side of the bridge during erecting.

After the bridge was erected, the falsework piles were broken off at the bottom of the river.

The railway company furnished all the material for the falsework, as well as for the bridge. The contract price of \$9 per lin. ft. of bridge covered the labor cost of erecting and removing the falsework, as well as framing and erecting the bridge. The cost of each of the 150-ft. Howe truss bridge spans was as follows:

88,600 ft. B. M. in bridge at \$15.....	\$1,329.00
45,600 lbs. wrought iron at 3.5 cts.....	1,576.00
38,800 lbs. cast iron at 2.5 cts.....	970.00
1,080 lin. ft. piles (18) in falsework at 8 cts....	86.40
4,000 ft. B. M. in falsework at \$15.....	60.00
Erecting 150 ft. at \$9.....	1,350.00

Total\$5,891.40

This is equivalent to \$36 per lin. ft. of bridge, exclusive of the piers and abutments.

There was no profit to the contractor at the \$9 per lin. ft. for erection, for it required 400 man-days per span. The average wages paid were \$3.30 per day. Hence the labor cost \$1,320 to erect the falsework and the Howe truss span. In our issues of June 26 and July 3 we have given in detail the labor cost of erecting similar bridges where the cost of erection was considerably less than in this instance. (See pages 1529 and 1532.)

The Steel Draw Span.—The span was 293 ft. long, and weighed 265 tons. The steel was unloaded from cars into a material yard and conveyed on scows to the "draw protection," where it was erected by means of a traveler.

The draw protection was built in the usual manner, consisting of pile bents 10 ft. apart, three piles to the bent, each pile being 70 ft. long. A log boom was built entirely around the draw protection, the opposite sides of the boom being held together by cross logs between the 2d and 3d bents and between the 5th and 7th bents. The boom was made of sticks 60 ft. long, held together with $\frac{1}{4}$ -in. chains and shackles.

The cost of the draw protection was as follows:

5,180 lin. ft. piles (74) at 8 cts.....	\$ 414.40
40,900 ft. B. M. timber at \$15.....	613.50
2,800 lbs. iron at 3 cts.....	76.00
680 lin. ft. of boom sticks at 8 cts.....	54.40
3,900 ft. B. M. timber wasted and in staging at \$15	58.50
Driving 74 piles at \$6.00.....	444.00
Framing and placing 40,900 ft. B. M. at \$8.....	327.20
Total	\$1,988.00

After the erection of the draw protection and the traveler and falsework, it required 38 days to erect the steel draw span.

In order to make sure that the panel sections of the top and bottom chords would come together before riveting, both ends of the draw bridge were jacked up after being erected and while temporarily held together with bolts. This brought all the joints of the top chord together, and, after riveting the entire top chord, the false work was knocked out, and in a suspended position the bottom chord was forced together and riveted. However, when the bridge was swung, it was found that the dead load was sufficient to cause the ends of the draw to sag to such an extent that they were $1\frac{1}{4}$ ins. below the proper level. This made it necessary to lower the pedestals on the rest piers a corresponding amount.

The cost of the draw span was as follows:

530,000 lbs. steel at 4.3 cts.....	\$22,802.90
21,100 ft. B. M. ties and guide rail \$15.....	316.50
Paint	380.00
Laying timber deck, 100 days, at \$3.30.....	330.00
Erecting bridge, including materials and labor on falsework (by contract).....	1,750.00
Total	\$25,579.40

This is equivalent to \$87 per lin. ft. of bridge, not including the cost of the piers and the draw protection.

The timber deck was laid as an "extra work job" by force account, and the labor cost at least twice what it should have cost, as can be seen by reference to costs of similar work in our issues of April 17, May 8, and May 29. (See pages 1501 and 1506.)

The contractor received only \$1,750 for erecting this 265-ton bridge, or \$6.60 per ton. It actually cost him nearly \$8.15 per ton for labor alone, for it took 800 man-days at \$2.70, or \$2,160, to erect the traveler, the falsework, and the bridge. It took 60 man-days to paint the bridge, at \$3.30 per day, or \$198, which is

equivalent to 75 cts. per ton, making a total of \$3.90 per ton for the labor of erecting and painting.

No record of the cost of falsework for this draw span is available, but it was a comparatively small item, for no lower falsework is necessary where a draw bridge is erected on the draw protection.

Cost of the Frazer River Bridge.—The Frazer River bridge at New Westminster, B. C., was built in 1902. It is a double deck bridge, the upper deck for wagon traffic and the lower deck for steam and electric traffic. The spans are as follows: One 225 ft., one 380 ft., and one swing span 380 ft., five spans 159 ft. each, making a total of 1,780 ft. On the north end there are three approaches, two for railway tracks and one for highway, the length of approach averaging about 300 ft. The clear roadway is 16 ft. wide, making the trusses 18 to 19 ft. c. to c. The weight of steel is 6,854,000 lbs., and there are 765,000 ft. B. M., and 15,000 lin. ft. piles in approaches. The contract price for substructure and superstructure was \$750,000.

Estimates of the Cost of Combination and All-Steel Highway Bridge of 190-ft. Span.—Mr. H. G. Tyrrell gives the following:

The bridge in question was a single span structure designed for the Pacific Coast. The trusses were to be pin-connected with 10 panels of 19 ft. each, and inclined top chord. The principal dimensions and specified loads were as follows:

Span, 190 ft. c. to c.

Roadway, 24 ft.

Two walks, each 6 ft. wide.

Total width of bridge, 41 ft.

Depth of trusses, 27 ft. to 33 ft.

Floor, 4-in. wood block paving on 3-in. plank, laid on wood joists.

Uniform live load on floor, 100 lbs. per sq. ft.

Concentrated load on floor, 15-ton roller or two electric cars on each track.

Live load, per lin. ft. of bridge, 3,300 lbs.

Dead load, per lin. ft. of bridge, 2,345 lbs.

For the "combination" design, hard pine was used for top chords, web posts, portals, lateral struts, floor beams and joists. The remaining parts were of steel.

The estimated quantities for this case were:

Eye-bars	42,180	lbs.
Cast-iron joint blocks.....	19,720	"
Lateral rods.....	5,810	"
Machined work.....	5,940	"
Shoe plates.....	5,200	"
Loops	3,160	"
Hangers	1,240	"

Total 83,250 lbs. **Cost \$ 3,180**

Hard pine chords and posts	17,500 ft. B. M.
Hard pine lateral struts,....	3,080 " "
Floor plank.....	19,740 " "
Floor joists.....	22,240 " "
Floor beams.....	14,800 " "

Total	77,360 ft. B. M.	Cost \$ 2,400
Paving 504 sq. yds.....	"	750
Fence, 400 lin. ft.....	"	200
Erection	"	1,200

Total cost of combination span = about \$1
per sq. ft. of total floor.....Cost \$ 7,680

For the all-steel design the quantities were:

Steel, 180,000 lbs.....	Cost \$ 7,360
Floor plank, 19 74 M; wood joist, 22.24 M....	" 1,436
Fence, 400 lin. ft.....	" 200
Paving, 504 sq. yds.....	" 750
Erection	" 1,200

Total cost of steel span, about \$1.43
per sq. ft. of total floor.....Cost \$10,945

The above estimates are for the entire superstructure in each case. If we compare now the cost of the substituted parts only, we have in the combination design, the top chords, web posts, portals, lateral struts and floor beams contain:

Hard pine, 35.3 M, at \$35 M.....	\$1,220
Cast iron joint blocks, 19,700 lbs., at 3 cts.....	591

Total

For the all-steel design the same parts contain:

Steel, 118,200 lbs., at 4 cts.....	\$4,720
------------------------------------	---------

Summarizing, we have:

Combination bridge.....	Cost \$ 7,680
Steel bridge.....	" 10,945
Combination chords, etc.....	" 1,811
Steel chords, etc.....	" 4,720

Hence, we may roughly that the combination bridge cost one-third less than the steel one. Also that the comparative cost of wood (including necessary cast-iron blocks), and steel for top chords, web posts, portals, lateral struts and floor beams, is as 1 to 3.

Cost of a 300-ft. Highway Drawbridge.—A highway drawbridge across the Harlem River, 8d Ave., New York city, was begun in 1893 and finished in 1896. The span is 300 ft. long; the width is 87½ ft. over all. There are four lattice trusses. The three carriage ways are each 20 ft. wide, and the two sidewalks are each 9 ft. wide carried on cantilever brackets. The floor is of buckle plates covered with concrete and asphalt pavement. The bridge weighs 2,500 tons, and is carried on a 50-ft. turntable. The time required for a full opening is 2 mins. and 2 mins. more for closing and locking. A 50-hp. engine does the work, but a duplicate power plant is provided.

The contract price was \$1,111,000 for the bridge complete, which is \$47 per sq. ft. of roadway and sidewalks. This is a very high cost. The total cost, including lands, was more than \$2,000,000.

The following are some of the important quantities and bidding prices:

	Unit prices.
107,500 ft. B. M. yellow pine in temporary bridge..	\$40.00
200,000 ft. B. M. hemlock in temporary bridge....	20.00
5,000 cu. yds. pneumatic caissons including concrete filling.....	29.00
Portland cement concrete, cu. yd.....	9.00
Natural cement concrete, cu. yd.....	5.40
Granite Ashlar facing below low water, cu. yd....	14.00
Granite Ashlar facing above low water, cu. yd....	20.00
Granite caps, cu. ft.....	2.50
Granite coping, cu. ft.....	3.00
Granite columns, capitals and bases.....	2.00
Granite dimension, in rough bases.....	0.50
Rough pointing, sq. ft.....	0.40
Fine pointing, sq. ft.....	0.50
Four-cut axing, sq. ft.....	0.50
Six-cut axing, sq. ft.....	0.60
Eight-cut axing, sq. ft.....	0.70
382,000 lbs. rolled steel and iron in turntable....	0.048
1,692,000 lbs. rolled steel and iron in draw span...	0.029
1,386,000 lbs. rolled steel and iron in deck spans..	0.027
4,200 lbs. corrugated plates, deck spans.....	0.024
257,000 lbs. buckle plates, draw spans.....	0.022
222,000 lbs. steel plate girders.....	0.022
420,000 lbs. steel rolled beams.....	0.025
117,800 lbs. castings in wheels.....	0.07
126,000 lbs. castings hub and bed plates.....	0.06
2,000 lbs. other iron castings.....	0.025
25,000 lbs. steel plates or angles.....	0.025

Cost of a Steel Arch Bridge.—The Cambridge Bridge across the Charles River (Boston) was built in 1901. It is a highway bridge, 1,768 ft. long, consisting of 11 spans of steel arches (of 12 ribs each), having spans varying from 101 to 188 ft. The height at the center is 48 ft. above low water. The bridge is 106 ft. wide between railings. From the bottom of the piles to the surface of the roadway is 100 ft. The construction involved 80,000 cu. yds. dredging, 35,000 cu. yds. concrete, 20,000 cu. yds. granite, 35,000 piles and 16,000,000 lbs. steel. The estimated cost is \$2,500,000, or \$1,400 per lin. ft., or \$14 per sq. ft.

Cost of Red Rock Cantilever Bridge.—Mr. S. M. Rowe gives the following data relative to this bridge, which was built in 1889 across the Colorado River in Arizona for the Atlantic and Pacific R. R. Co. (See p. 1418 for the cost of the caisson.)

The bridge was designed for a live load of two engines, each weighing 125,000 lbs. (including 74,000-lb. tender), concentrating 46 tons on a wheel base of 11 ft. 9 ins., followed by a train of 2,000 lbs. per ft.

The length of the cantilever bridge is 990 ft.; the span between the piers being 660 ft., and each anchor arm being 165 ft.

The following is the weight of metal in the bridge:

	Lbs.
East anchorage, exclusive of floor beams.....	78,435
West anchorage, exclusive of floor beams.....	92,488
Floor of anchor and cantilever arms.....	271,510
Two anchor arms.....	969,870
Two cantilever arms.....	969,870
Metal over piers (posts, etc.).....	178,790
Expansive panels (chords and X posts).....	128,170
Temporary members (wedges, reinforced bars)...	76,040
Suspended span.....	701,975
Total	3,416,618

About 70% of this was steel and 30% iron.

The cost of this superstructure was as follows:

Iron and steel erected (including freight)....	\$213,537.82
Timber	1,684.68
Tools and materials.....	625.58
Fuel and water.....	1,340.94
Local and train service.....	1,202.78
Labor in addition to contract work.....	2,138.79
Engineering	9,624.14
Total	\$230,154.74

The cost of the substructure was as follows:

Caisson (see page 1617 for details).....	\$128,263.19
Masonry piers and abutments.....	80,267.65
Preparatory	23,748.10
Total	\$232,278.94
Grand total.....	\$462,433.68

This is equivalent to \$463 per lin. ft.

The "preparatory" work consisted of the following items:

Soundings	\$ 7,808.79
Trestle and tracks to caisson.....	4,238.17
Track to quarry.....	7,213.58
Freight	525.15
Demurrage	900.00
Engineering	962.41
Total	\$23,748.10

The cost of this bridge was unusually high.

Estimated Cost of a Cantilever Bridge and of a Suspension Bridge Across the St. Lawrence.—In 1896 the Montreal Bridge Company received competitive plans and estimates for a proposed bridge across the St. Lawrence River at Montreal. The bridge was specified to be one channel span of 1,250 ft., two side spans of 500 ft. each, 15 steel viaduct spans on south approach of 250 ft. each, 18 viaduct spans on north approach of 60 to 240 ft. each, the clear headway in the channel span to be 150 ft. The bridge was to be for a double track steam railway, two street railway tracks, a carriageway and two sidewalks. The piers of the cantilever were to be of masonry.

The prize plan was submitted by Edward S. Shaw of Boston. He increased the side spans to 600 ft. The bridge was designed

to be 80 ft. wide, with four trusses. The stone sub-piers are each 30 x 110 ft. in plan on top, 60 ft. above low water, surmounted by steel piers 230 ft. high. The middle roadway is 26 ft. wide and is for the double track railway; the two side roadways are each 21½ ft. wide; flanked by 6-ft. sidewalks on brackets. The estimated weight of structural steel was:

	Lbs.
Main cantilever and central span.....	39,450,000
South viaduct approach.....	26,340,000
North viaduct approach.....	8,200,000
Total	74,000,000
Estimated cost of superstructure.....	\$2,514,000

This is about 4¼ cts. per lb. It would appear from one of the estimates made by another competitor that custom's duty of 1 ct. per lb. of steel ready for erection would be required.

A suspension bridge design was submitted by Mr. C. C. Wentworth, M. Am. Soc. C. E. It was to be a stiffened suspension bridge of 1,300 ft. span, with two 500 ft. side spans supported from the cables, giving a total length of 2,300 ft. There were to be 4 cables, each of 17½ ins. diameter. The two stiffening trusses were to be 52 ft. apart on the clear, leaving the roadway for the railway and electric lines. The carriageways and sidewalks were to be on brackets outside the trusses.

The estimated cost was as follows:

11,000,000 lbs. riveted steel center span, at 4.25 cts.....	\$ 467,500
20,000,000 lbs. steel in towers, side spans and anchorage, at 3½ cts.....	700,000
30,000,000 lbs. steel in viaduct spans and towers, at 3 cts.....	900,000
8,000,000 lbs. wire in cables, at 6 cts.....	480,000
Copper covering on cables.....	20,000
Timber floors and ties.....	81,000
600 tons steel rails.....	18,000
Hand railing.....	25,000
60,000 cu. yds. anchorage masonry.....	260,000

Total for superstructure and anchorage.....\$3,051,500

It will be noted that if the same unit prices for steel had been assumed in both styles of bridge, the cost would have been more nearly equal, although about 7 per cent less for the suspension bridge.

Cost of the Brooklyn Suspension Bridge.—The Brooklyn Bridge across East River, New York City, was begun in 1870 and finished in 1883. Work was suspended at times due to lack of funds, so that the actual building required only 10 of the 13 years.

The roadway is 86 ft. wide, divided into five sections, two outside for vehicles and trolley cars, two inner for electric trains, and the middle one (12 ft.) for pedestrians. Height of bridge above high water in center, 135 ft.; height of masonry towers above high water, 272 ft. The Manhattan tower contains 46,945 cu. yds. of masonry. The Brooklyn tower contains 38,214 cu. yds. The depth of the Manhattan tower foundation below high water is 78 ft. The depth of the Brooklyn tower foundation below high water is 45 ft. Dimensions of towers at high water line, 59 x 140 ft.

The cost of the bridge and approaches was \$9,000,000, or about \$1,500 per lin. ft., or a little more than \$17 per sq. ft. The cost of real estate and terminals was about \$6,000,000 additional.

Comparative data as to the Brooklyn and Williamsburg bridges are given below.

The weight of the 1,545 ft. of main span of Brooklyn bridge between end suspenders is as follows:

	Lbs.
Cables	3,226,000
Suspended superstructure (steel work)	5,930,000
Timber flooring, track, etc.	2,380,000
Hauling, electric feeder, cables and line sleeves..	220,000
Pneumatic tubes	262,000
Suspenders and connections	356,000
Over-floor stays (vertical loads)	386,000
Total fixed load on main span	12,760,000

Cost of the Williamsburg Suspension Bridge.—The Williamsburg bridge, across East River, at Delancy St., New York City, is the longest suspension bridge in the world, and its main span is exceeded only by the Forth cantilever bridge in Scotland. It was begun in 1896 and finished in 1903. The roadway is double deck, distributed as follows:

2 footwalks, each 10½ ft.	21 ft.
2 bicycle paths, each 7 ft.	14 ft.
2 elevated railway tracks	22 ft.
4 trolley tracks	40 ft.
2 roadways	40 ft.

Equivalent width single-deck bridge

The width of the main span is 118 ft. over all.

The comparative dimensions of the Williamsburg bridge and the Brooklyn bridge are given in Table II.

Table II—Comparative Dimensions of Williamsburg and Brooklyn Bridges, New York City.

	Bridges.	
Length:	Brooklyn.	Williamsburg.
Main span C. to C. of towers	1,595' 6"	1,600' 0"
Land spans, tower—anchorage	930' 0"	598' 6"
Brooklyn approach	971' 0"	1,885' 0"
Manhattan approach	1,562' 6"	2,806' 2"
Total of carriage way	5,989' 0"	7,264' 2"
Height:		
Clear, above M. H. W. at center	135' 0"	140' 4½"
Same, 200' each side of center		135' 0"
Above M. H. W. to center of cable at tower	272' 0"	332' 8½"
Above M. H. W. to roadway in center of span	138' 3"	145' 5½"
Same, at center of tower	119' 3"	125' 7½"
Of tower above roadway	159' 0"	210' 0"
Width of bridge	85' 0"	118' 0"
Grade of roadway in 100 ft.	3' 3"	3' 0"
Max. grade of roadway in 100 ft.	3' 9"	3' 4½"
Foundation below M. H. W.:		
Brooklyn	45' 0"	N. 107.5'
Manhattan	78' 0"	N. 65.0'

Size of Caissons:

Brooklyn	168 x 102'	(2)	63 x 79'
Manhattan	172 x 102'	(2)	60 x 76'

Size of anchorages:

At base—Brooklyn.....	129 x 119'	177 x 158'
At base—Manhattan.....	129 x 119'	173' 4 1/2" x 151' 9"
At top	117 x 104'	149' x 127' 5"
Diameter of cables.....	15 3/4"	18 3/4"
Number wires in each cable.....	5,296	7,700
Length of wire weighing 1 lb.....	12'	10' 8"
Weight of one cable per lin. ft.....	500 lbs.	770 lbs.
Total miles of wire in 4 cables.....	14,361	17,432
Versine at mean temperature.....	128'	179'
Ultimate strength each cable, tons....	12,200	24,500
Permanent weight suspended:		
From main span cables, tons.....	6,780	13,740
From shore span cables, tons.....	7,900	0

The main towers of Williamsburg Bridge are of steel, 310 ft. high from top of masonry to center of cable over the tower.

The quantities of the principal materials were as follows:

	Lbs.
2 towers	12,182,000
2 end spans.....	12,280,000
1 main suspended span.....	15,544,000
Cables and suspenders.....	10,000,000
Brooklyn viaduct approach.....	12,170,000
New York viaduct approach.....	21,100,000
In anchorages.....	5,200,000
Total	89,486,000
Concrete, cu. yds.....	60,000
Stone masonry, cu. yds.....	130,000
Excavation, cu. yds.....	126,000
Timber, ft. B. M.....	8,000,000

The cost of the bridge was \$11,000,000 (exclusive of land), and some of the items were as follows:

Anchorage, Brooklyn side.....	\$ 771,778
Anchorage, Manhattan side.....	797,770
Tower foundation, Brooklyn.....	485,082
Tower foundation, Manhattan.....	373,452
Suspended span.....	1,123,400
Brooklyn viaduct approach.....	947,000
New York viaduct approach.....	1,464,000
Cables	1,398,000

Cost of Two Pneumatic Foundations for the Williamsburg Bridge.

—The following data were given by Mr. Francis L. Pruyn in *Engineering-Contracting*, Aug. 8, Aug. 15, and Aug. 22, 1906:

The work here described consisted of sinking two large caissons, 63 x 79 ft. in size on the Brooklyn side of the Williamsburg Bridge to bed rock, in one case 88 ft. and in the other 110 ft. below mean high water, filling same with concrete and building masonry piers upon this foundation inside of coffer dams up to elevation plus 23 ft. above M. H. W. All work was done by contract during the years 1897 to 1899.

The caissons were constructed of yellow pine timber at the site of the work, launched, floated into place and sunk to the river

bottom, which was about 55 ft. below M. H. W., by filling them with concrete.

Compressed air was then turned on, and the caissons were sunk to bed rock. The material encountered, consisting of river mud, sand, clay and rock, was excavated either by means of Moran patent material locks or by wet blow out; finally the working chamber was filled with concrete. While the caissons were being sunk, the coffer dams, which were attached to the caissons, were added in order to keep their tops above water, and inside of these coffer dams the masonry piers were built. During the sinking process the masonry was built only in sufficient quantity to give the weight necessary for sinking the caissons. After the caissons were sealed and the air taken off, the shafting and piping were removed, the spaces occupied by them filled with concrete, and the pier carried up to its final elevation. The coffer dams were then removed.

The costs recorded were kept by daily engineer's force account, and are as accurate as is possible by that method. The plant charges were obtained by a careful inventory, to which prevailing prices were affixed. Depreciation was charged off at about 40 per cent, which is perhaps 10 per cent too low. The general expense was 10 per cent of the total cost of materials and labor and included bond, interest on money invested, office and dock rentals, superintendent and field office salaries, watching, etc. No allowance was made for maintenance of main office.

Cost of Two Caissons.—The caissons were 62 x 79 ft. in size; the south one was 29 ft. high and the north 52 ft. high. They were built one at a time, directly at the site of the work; the launching ways extending back from the bulkhead line. A floating pile driver fitted with a 70-ft. boom was used to build them. This served its purpose well, as the heel of the boom could be raised as the caissons were built up. When the caisson walls were 30 ft. high the caissons were launched and towed to site, where they were completed. The framing and building was done under the direction of a very capable foreman, who obtained good and rapid work from his carpenters. All framing was done by hand; a steam auger was used where practical for boring bolt holes, and a steam hammer was used part of the time for driving drift bolts. The sides and roof of caisson were built up of two courses of 12 x 12 timber, the outside was sheathed with two courses of 3-in. tongue and groove plank. There was also two courses of 3-in. plank in the roof. Above the caisson roof a cribwork of 12 x 12-in. timbers divided the space inside the walls into pockets 6 ft. square. This cribwork was trussed by means of 3-in. plank spiked on; it served to keep the weight of concrete and pier masonry off the roof.

The working chamber, which was 7 ft. high, was divided by suitable bulkheads. In order to secure air tightness the seams were calked with two strands of oakum well forced in. The chamber was then lined with 3-in. plank, the joints of which, as well as the spikes used in fastening same, were also treated with two strands of oakum and afterwards painted with white lead.

The labor prices paid per 10-hour day were as follows:

Foreman	\$5.00
Sub-foreman	3.00
Carpenter	3.00
.....	2.50
Riggers	2.00
Holst Runners.....	2.50
Steam Fitters.....	3.00
.....	2.50
Blacksmith and Helpers.....	4.00
Laborers	1.50
Calkers	3.25

It will be noted that these rates are from 20 to 50 per cent lower than the present rates, which are now based on an 8-hour day for municipal work.

The south caisson was built first, and the difference in cost between it and the north caisson was brought about by the better organization on the second caisson, and by the larger quantity of the cheaper kind of framing in the cobwork and walls above the roof. The cost of material and labor is given in Table III.

Figures 1 and 2 show the general construction of the caissons, method of framing, etc. [The figures are given in *Engineering-Contracting*, but omitted here on account of their size.] It is of interest to note the increase in prices of yellow pine timber and other materials that had taken place since this work was done.

The South Caisson was begun Aug. 13th, launched with walls 20 ft. high Oct. 19th and finished to 39 ft. high Nov. 17th.

The North Caisson was begun Oct. 20th, launched Nov. 30th and finished to 53 ft. high Feb. 8th, 1898.

Launching Ways.—The caisson as launched 30 ft. high weighed 954 tons and drew $11\frac{1}{2}$ ft. of water. The ways, four in number, were placed one under each outside wall and one under each bulk head. They consisted of two 12 x 12 timbers bolted side by side, sliding on two similar timbers fastened to the caisson. Three-inch plank were bolted to the outside of the ways to serve as guides. They were sloped $1\frac{1}{2}$ ins. to the foot, and extended 5 ft. below M. H. W. The pressure on the ways was 255 lbs. per sq. in. and they were lubricated with a mixture of tallow and graphite.

Cost of Two Coffer Dams.—Coffer dams 50 ft. high were attached to the caissons in order to allow sinking to proceed independently of, and without waiting for, the construction of the masonry, and also to keep the pressure on the cutting edge of the caisson under perfect control. The coffer dams were attached to the caissons by removable bolts, and built up in three sections 17 ft. high. The thickness of the walls diminished from 12 ins. on the bottom section to 6 ins. on the top and the interior horizontal bracing provided for 13 ft. pockets for setting the masonry. The bracing was trussed with 3-in. plank in the same manner as the caissons, but so arranged that it could be removed as the pier masonry was built up.

The coffer dams were built at night to avoid interference with other work. The cost of the material and labor is given in Table IV.

TABLE III.—TOTAL COST OF TIMBER WORK ON CAISSONS.

Materials.	South Caisson.			North Caisson.		
	Quantity.	Rate.	Amount.	Quantity.	Rate.	Amount.

Grand total.....	309 M	\$48.75	\$15,037.00	208 M	\$55.04	\$12,549.00

It was found after the south coffer dam was built that the walls were unnecessarily heavy. This was corrected in building the north coffer dam, which accounts for its increased cost per M. ft. B. M.

Figure 3 [not reproduced here] shows the general design and details of the coffer dam construction, as well as method of temporary attachment to caissons.

Concrete in Caissons.—After each caisson was built it was towed to its proper site, where it was held in place by temporary pile dock built completely around it. On these docks the concrete was placed; a 2 cu. yd. cubical mixer of the usual pattern being used for mixing. The concrete materials, consisting of sand, stone and cement were handled direct from barges alongside, into the mixer. The concrete was placed by a derrick located in the center of the caisson, which was a bad feature as the caisson was usually out of level and considerable difficulty was experienced in swinging the derrick. On the south caisson $\frac{3}{4}$ cu. yd. bottom dump buckets were used in placing the concrete, on the north caisson the size of these was increased to $1\frac{1}{2}$ cu. yd. which reduced the cost of placing 15 cts. per cu. yd. There were placed in the south caisson 3,827 cu. yds. in 32 days of actual working time—120 cu. yds. per day of 10 hrs. The gross time was 2 months. On the north caisson 5,698 cu. yds. were placed in 46 days worked—124 cu. yds. per day. The gross time was 4 months. See Table V.

The rates of labor were as follows per 10-hour day:

Foreman	\$5.00
Assistant foreman.....	2.50
Holsters	2.50
Fireman	1.60
Laborer	1.50

Proportions concrete were 1 : 2.5 : 6.

The low price of sand in the north caisson was brought about by the finding of good building sand in the excavation for the anchorage, which work was done by the same contractor.

When the caissons had been sealed the iron material shafts were removed. This left holes 5 ft. x 6 ft. extending from the roof of the caisson up to M. H. W. which were filled with concrete. These shaft holes were 80 ft. deep on the south caisson and 100 ft. deep on the north caisson. They were partially filled with water and the concrete had to be placed with considerable care. Wooden chutes were used on the south caisson; they rested on the caisson roof, were filled with concrete and then raised allowing concrete to flow out at the bottom. The shaft holes were too deep on the north caisson for chutes and 20 cu. ft. bottom dump buckets were used. They had to be lowered to bottom of shaft each trip before dumping, a slow operation, which greatly added to the cost. Proportion for concrete 1 : 2.5 : 6. See Table VI.

The proportion for concrete in working chamber was the same as for all other concrete. The specifications called for 6 in. of mortar, of 1 part of cement to $2\frac{1}{2}$ parts of sand and between the concrete and all bearing areas; that is, under the cutting edge and

TABLE V.—COST OF CONCRETING CAISSONS ABOVE ROOF.

	South Caisson (3,827 cu. yds.)			North Caisson (5,693 cu. yds.)		
Materials.	Quantity.	Rate.	Amount.	Quantity.	Rate.	Amount.
Cement	4,480 bbls.	\$1.57	\$ 7,034.00	6,707 ½ bbls.	\$1.57	\$10,531.00
Sand	1,288 cu. yds.	.60	772.80	2,133 cu. yds.	.40	845.00
Broken stone	3,421 cu. yds.	1.50	5,132.00	4,988 cu. yds.	1.10	5,432.00
Water			36.00			51.00
Total	3,827 cu. yds.	\$3.39	\$12,975.00	5,693 cu. yds.	\$2.96	\$16,859.00
Labor.						
Mixing and placing	3,827 cu. yds.	\$0.90	\$ 3,432.00	5,692 cu. yds.	\$0.73	\$ 4,159.00
Plant charges			2,280.00			2,952.00
Plant labor			742.00			517.00
Total plant	3,827 cu. yds.	\$0.79	\$ 3,022.00	5,692 cu. yds.	\$0.61	\$ 3,469.00
Total cost	3,827 cu. yds.	\$5.08	\$19,429.00	5,692 cu. yds.	\$4.30	\$24,487.00
General expenses, 10%	3,827 cu. yds.	.51	1,943.00	5,692 cu. yds.	.43	2,448.00
Grand total	3,827 cu. yds.	\$5.59	\$21,372.00	5,692 cu. yds.	\$4.73	\$26,935.00

directly under the roof of the working chamber. The concrete was mixed in the cubical mixer and dumped on the bottom door of the material lock, the top door of the lock was then closed, the bottom door opened and the concrete fell through the shaft to the working chamber. It was then shoveled by the sand hogs into place. A 6-in. space was left below all bearing surfaces into which damp mortar was tightly rammed. Concreting the south caisson took $10\frac{1}{4}$ working days of 24 hours, the gangs working night and day in twelve 2-hour shifts; 1,566 cu. yds. of concrete and mortar were placed, or at the rate of 140 cu. yds. per 24 hours. The gross time including Sundays was $14\frac{1}{2}$ days. The sand hogs worked in shifts of 2 hours each and received \$3.50 for the two hours work. The twelve foremen received \$1 more; the average gang consisted of 12 sand hogs.

On the north caisson the organization was much better, owing to the experience gained on the first caisson; and in spite of the fact that the sand hogs, on account of the increased depth, received \$4.00 for $1\frac{1}{2}$ hours work, or an increase of \$32.00 per man per 24 hrs. over that on the south caisson, the work was done for less money. There were placed 1,566 cu. yds. of concrete in 7 working days of 24 hrs., or at the rate of 224 cu. yds. per day. The gross time was $11\frac{1}{2}$ days including Sundays. The average number of men in the sand hog gangs was 18, with one foreman, who received \$5 for $1\frac{1}{2}$ hours work. See Table VII.

Cost of Sinking Caissons.—The cost of sinking caissons has been subdivided according to the materials encountered and also with reference to the depth of cutting edge, as the price paid the pressure men varies with the depth. The following were the union rates paid to "sand dogs," or workmen:

From 0 to 50 ft. below M. H. W.....	\$2.50 for 8 hours
55 to 70 ft. below M. H. W.....	2.75 for 6 hours
70 to 80 ft. below M. H. W.....	3.00 for 4 hours
80 to 90 ft. below M. H. W.....	3.25 for 2 hours
90 to 100 ft. below M. H. W.....	3.50 for 1 hour
100 to 110 ft. below M. H. W.....	3.75 for 1 hour

When connecting chamber, the price was increased 25 cts. per shift.

Compressor engineers received \$3.60 per day, foremen \$3.60 and coal passers \$2. The superintendent in charge of the pneumatic work received \$6 per day and his night assistants \$5.

The present "sand hog" rates have increased 20% over these figures.

The air plant consisted of three 100-hp. vertical boilers, 3 Laidlaw-Dunn-Gordon Duplex Compressors, 16-in. steam and 18-in. air cylinders with 18-in. stroke, and two high pressure force pumps. One 6-in. pipe supplied air to the caissons, and one 5-in. pipe supplied the water. There were also three 4-in. blowout pipes, six 3-ft. material shafts and one 6-ft. man shaft with elevator. Docks were built around the caissons to hold them in position while sinking; on one of these the compressor plant was located. The clay encountered was a very hard stratified material and difficult

to excavate. The rock was the ordinary New York gneiss and was drilled by hand. The cost of plant was estimated from inventory taken, as the prices paid for it were not available. The supplies also had to be estimated, and the charge for them, as well as the plant are, probably 10 to 15% low.

Cost of Sinking South Culison—

(1) Sand with boulders, 3 gangs per day at 8 hours each. Elevation—52.5 ft. to —56.25 ft.	
Labor sinking	\$1,583.00

The cost of stripping and cleaning up rock is excessively high, but this work is necessarily slow, the quantity of actual excavation small and the labor rate of from \$1.75 to \$1.87 per hour is about 10 times that for similar work above ground. The fixed plant and overhead charges are likewise heavy.

The same explanation applies to the high rock excavation cost, besides which very small charges of powder had to be used owing to danger of injuring the caisson, as well as the danger of blow-outs under the cutting edge. Therefore holes had to be drilled close together.

All drilling was done by hand; power drills would have greatly reduced the cost. The delay caused by blasting is expensive in this class of work; the whole gang has to go up in the airlock at almost every shot.

Cost of Pier Masonry.—The masonry was begun at the elevation of the top of the caissons and carried up to elevation 24 ft. above M. H. W. in courses varying from 2 ft. 6 ins. in thickness at the bottom to 2 ft. at the top. The pier was built of limestone up to 4 ft. below M. L. W., above which the facing was of rock faced granite with the backing of limestone. The two top courses, as well as the pedestals, were built entirely of granite, all exposed surfaces of which were 6-cut. All other face stones, whether of limestone or granite, were of rock faced with ½-in. beds and joints. The backing was built of roughly squared stones with ½-in. beds, and 3-in. joints. Spalls were used in filling the joints. See Table VIII.

Cramps and dowels were used in the two top courses of granite.

The plant consisted of derricks surrounding each pier. The limestone was unloaded direct from barges. Two extra barges were kept continuously at the site for storage purposes. The

granite was unloaded, cut and stored on adjacent docks rented for the purpose. The mortar was mixed by the concrete plant in proportions, 1 of cement to $2\frac{1}{2}$ of sand, and handled in buckets by the derricks.

The interference on this class of work is great, and the organization that can be attained where masonry work alone is carried on, is not possible. The coffer-dam braces interfere with the progress, as well as the fact that the quantity of masonry which can be set while the caisson is being sunk depends on the weight required on the cutting edge and not on the efficiency of the masonry gang. The first pier was built in 122 gang days, or at the rate of 56 cu. yds. per day; the second one was completed in 77 gang days, or at the rate of 90 cu. yds. per day. This increased performance was made possible by the more rapid sinking of the second caisson as well as by better organization.

In the total masonry for both piers up to the coping courses the voids were—in backing 12%, in face stone 8%. In the coping courses the voids were $3\frac{1}{2}$ %.

The labor rates were as follows per 10-hour day:

	Per day.
Foreman	\$5.00
Assistant foreman	4.50
Masons	3.20
Stone cutters	3.00
Hoister runners	2.75
Laborers	1.50

Cost of Erecting the Brooklyn Towers and End Spans of the Williamsburg Bridge, New York City.—The following data were given by Mr. Francis L. Pruyn in *Engineering-Contracting*, Oct. 24, 1906:

The work consisted of the erection complete in place, of a steel tower 310 ft. high on the tower foundations, the erection of truss 596 ft. long, the connecting of the same with the cable anchorage, and the construction of an intermediate tower about 100 ft. high supporting the center of the end span.

Main Tower.—The main tower consisted of eight heavy columns braced laterally in all directions. At the floor level they were provided with a system of heavy girders to support the end of the land truss as well as the end of the suspended structure, the main span of the bridge. At the top of the tower another system of heavy girders was provided on which rested saddles for the cables of the suspended structure.

The actual erection of falsework for the main tower began in January, 1900, and the erection and painting of steel work was finished in November, 1901. The falsework consisted of a heavy flooring resting on seven 60-ft. trusses extending between the masonry piers. On the floor was placed the boilers and engines which were used for raising all steel work for the tower. The main falsework, consisting of a heavily braced timber tower, was put up in three sections. The first section extended to the roadway level, and was about 100 ft. high. On top of this

were erected two heavy A frame derricks for hoisting the steel and two smaller derricks for handling the lighter parts. The steel work was then erected up to the roadway level. On top of the roadway the second section of timber tower was erected about 107 ft. high, the derricks were transferred to its top, and the steel work erected as far as possible. The first section of falsework tower below the roadway was then wrecked and re-erected on top of the second section, the derricks again transferred, and the erection of tower completed. After steel tower was erected a heavy timber gallows frame was built on top of it for hoisting the cable saddles into place.

In the erection of falsework; steel work, etc., the Bridgemen's Union was employed. The rate of wages for its members was \$2.20 for eight hours at the start of the work; later the rate was increased to \$3.76 per day. The general rate of wages for the erection of falsework for main towers for an eight-hour day was as follows:

Foremen	\$5.00
Sub-Foremen	3.50
Carpenters and steel men.....	3.20
Holsters	1.50
Laborers	2.00

The cost of erecting the falsework for the main towers is shown in Table IX.

TABLE IX.—COST OF ERECTING FALSE WORK FOR MAIN TOWERS.

Plant			1,314.00
Plant, labor.....			1,285.00
General expenses, 10%.....			2,326.00
Total			\$25,583.00

The total weight of the tower was 3,071 tons, therefore the falsework cost \$8.32 per ton. It should be noted that no salvage has been allowed on timber or iron.

False Work for End Span.—The false work for the end span consisted of a heavy timber structure about 575 ft. long and averaging about 30 ft. in height. The bents were made up of 12 x 12-in. yellow pine timber fastened together with iron fish plates and $\frac{3}{4}$ -in. bolts and braced with 5-in. sway bracing. The portion from the main towers to the bulkhead, about 180 ft., was built on a pile trestle in 50 ft. of water. A 40-ft. truss spanned Kent Ave. A traveler was built on top of the false work by means of which the steel work was erected.

Cost of Pile Dock.—The pile dock was built in 50 ft. of water, where the current ran at times 6 miles an hour. The river bottom was hard and the piles did not penetrate over 10 ft. For these reasons it was built much more carefully than is customary with this class of temporary structures. The piles were of Norway pine, 70 ft. long with 18-in. butts. The capping was of 12 x 12-in. yellow pine timber carefully framed and heavily bolted. The whole was braced by 12 x 12-in. and 4 x 12-in. timber.

The labor rates for a 10-hour day were:

Foremen	\$5.00
Dock builders	2.25
Hoisters	2.50

The dimensions of the trestle were 190 ft. x 89 ft., making a total of 16,900 sq. ft.

General expenses, at 10%.....	1,367.00
	<u>\$15,040.00</u>

There were 16,900 sq. ft. of dock, which, therefore, cost \$9 cts. per sq. ft.

False Work Trestle for End Span.—The false work for the cantilever span, which extended from the intermediate tower to the

anchorage, consists of 17 bents 20 ft. apart, and from 60 ft. to 90 ft. high and included the truss across Kent Ave., which was made up of nine trusses 48 ft. long and 15 ft. deep. After the cantilever span was erected, seven bents were moved forward to serve as false work for the connecting span and the remainder of the steel work erected. The timber bents were erected stick by stick in place, and not, as is customary, by building on the ground and erecting the bent as a unit.

The steel work was erected by means of a traveler running on tracks on top of the false work. It was 45 ft. square by 47 ft. high, and was furnished with four 10-ton derricks, which were mounted on top of it. A 20-ton derrick was set up on the extreme end of the false work for raising the steel from the ground to cars on top of the false work. As in the case of the false work for the towers, all labor had to be furnished by the Bridgemen's Union.

Total	\$23.08	\$60,845.00

The total weight of steel erected in intermediate tower and end span was 2,636 tons; the false work, therefore, cost \$23.08 per ton of steel.

It should be noted that no salvage has been allowed for timber and iron, as there was no means of determining what was the ultimate value of this material.

Cost of Erection of Main Towers.—Erection of main towers was begun Feb. 1, 1900, and was completed, with the exception of placing the saddle on top of the tower on Oct. 1st of the same year. The last saddle was set Dec. 14. The first section erected, which extended up to the roadway level, or to elevation 125 ft. above mean high water, contained the heaviest members, and should have been the cheapest to erect. The delivery, however, was slow and the organization not yet perfected. The second section erected extended to elevation 232 ft. above mean high water, and contained a great deal of light and intricate cross bracing, which accounts for its higher cost. In the top section the steel was delivered promptly, and the construction was simple and free from detail work.

The prices paid to labor, per day of 8 hours, were as follows:

Foremen	\$6.00
Sub-foremen	3.75
Holsters	3.50
Steelmen	3.50
Laborers	2.00

The plant consisted of two 40-hp. 10-in. x 12-in. boilers, one 25-hp. 8-in. x 10-in. double-cylinder, 4-drum engine, and one small donkey engine. Charging these off at 50%, the total plant charge, including steel cable, rope, small tools, coal, etc., was \$5,000.

The cost given in Table X does not include the cost of riveting, which is treated separately.

The incidental expenses were as follows:

Preliminary work.....	\$ 627
Fitting steel at top of towers, chipping roller beds, etc.....	1,221
Placing anchor bolts.....	45
Diamond-drilling 32 anchor-bolt holes.....	4,000
Rust joints materials.....	931

Total\$6,814

Erecting End Span.—This work consisted of erecting the intermediate tower and the land truss, which extended from the main towers to the anchorage, a distance of 800 ft. The truss was 40 ft. deep by 67 ft. wide, with a roadway 25 ft. in width extending beyond the truss on each side. The span was made up of two heavy trusses, divided into 20-ft. panels, and complicated with a multitude of details owing to the various kinds of traffic that had to be taken care of on this bridge.

The intermediate tower on which the cantilever span rested was 90 ft. in height, and rested on two masonry piers 67 ft., center to center. Each pier supported four steel columns, with diagonal bracing and connected across at the top with heavy beams. All material was brought to the site on floats, and was unloaded by means of a derrick situated at the main tower. The material was placed on flat cars, which ran on a trestle about 6 ft. above mean high water, and was pushed by hand to the foot of the false work extending just beyond the intermediate towers. Here it was hoisted to cars running on top of the false work and placed under the traveler, which erected it in position.

The erection of the intermediate tower was begun in April, 1900. The erection of the end span was finished in March, 1901. The cost of labor was the same as for the main tower, with the exception of the holsters, runners and steelmen, whose rate was increased to \$3.76 per day of eight hours.

The plant consisted of three second-hand 25-hp. engines, double-cylinder 8 in. x 10 in., with six drums and boilers, and cost, at 50%, \$1,500. The cost of rope, small tools, etc., was \$1,300, making the total cost \$2,800. The total cost of erection is given by Table XI.

The incidental expenses were:

Preliminary work.....	\$ 500
Rust joints.....	150
Adjusting errors in steel work.....	696
Removing steel for cables.....	1,006
<hr/>	
Total	\$2,352

Riveting on Main Towers and End Span.—The riveting was done with pneumatic riveters; from four to eight guns were generally in use. Four men, including the rivet heater, constituted a gang; each man received \$3.76 per day of eight hours. Compressed air was furnished at about 80 lbs. pressure by two compressors, with a combined capacity of about 800 cu. ft. per minute. The rivets used on the intermediate tower were short and easily driven, as indicated by the cost given in Table XII, while the heavy sections

Plant, labor, miscellaneous.....	3,290

Total\$9,610

Painting Main Tower and End Span.—The cost of the first coat of paint on the main tower and end span was about double what it should have been on account of the bad condition of the shop coat, which had to be scraped off in many places before the first coat could be applied. A fair average would be to figure painters employed one-half time in preparing the surface.

TABLE XIII.—COST OF PAINTING STRUCTURE.

Painters received \$2.25 per day of eight hours, but painted only the first coat on the main tower. After that steelmen were employed at \$3.76 per day. Table XIII shows the cost of painting. The cost of the plant was as follows:

Brushes, pots, etc.....	\$ 214
Scaffolds, ladders, etc.....	312
Anchorage protection.....	345
Miscellaneous plant labor.....	903

Total\$1,775

General Expense.—The general expense on this work includes the resident engineer, draftsman, superintendent, timekeepers, office help and watchman; and figured out 10% to the cost of the total labor and materials employed at the site of the work.

As previously noted, the large cost for falsework is brought about on account of not crediting salvage on the materials on this item. Table XIV gives the total cost of the completed work.

TABLE XIV.—TOTAL COST OF COMPLETED WORK.

	Main Tower. 3,071 Tons.	End Span. 2,636 Tons.	Total 5,707 Tons.	Cost Per Ton.

24 bbls. No. 20 National Paint Works, Spec. 1,103	
Turpentine	80
Linseed oil.....	160
Total	\$2,980

Cost of the Brooklyn Anchorage of the Williamsburg Bridge.—The following data were given by Mr. Francis L. Pruyn, in *Engineering-Contracting*, Jan. 30, 1907:

The Brooklyn anchorage of the Williamsburg Bridge consisted essentially of a block of masonry 150 ft. long, 132 ft. wide and 114 ft. high. Its function was to furnish sufficient weight to hold down the cables when the main span of the bridge was fully loaded. Fig. 1 [too large for reproduction here] shows the main feature of the design; which included an excavation 40 ft. deep, a pile and timber grillage foundation, over which was spread a 14-ft. layer of concrete. From this point to the elevation of the ground, a distance of 25 ft., limestone masonry was placed, and from this elevation to the top of the anchorage the masonry consisted of limestone backing with granite face-stone.

The interior of the anchorage contained three tunnels extending from top to bottom in which were placed the steel anchor chains. These chains were fastened at the bottom of the anchorage to a heavy steel grillage which was firmly imbedded in the masonry. The anchorage also contained two large wells situated between the lines of anchor chains, which were necessary in order to obtain an equal load distribution on the foundation. The main items in this contract were as follows:

Earth excavation	34,040 cu. yds.
Yellow pine piles.....	432
Yellow pine timber.....	120,000 cu. ft.
Concrete	10,895 cu. yds.
Stone masonry	44,597 cu. yds.
Steel anchor chains	1,553 tons.

Cost of Excavation.—The anchorage was situated about 360 ft. from the East River bulkhead line and a trestle was constructed to carry the excavated material across the intervening street to a dumping-board, where it was loaded directly into scows and carried away to sea. Tracks were laid on this trestle and cars which

were actuated by an ingenious form of cable haul handled the excavated material. This trestle and hauling device also served to handle all the material for grillages, concrete, stone masonry, steel work, etc.

The excavation was done by pick and shovel into skips, which were elevated and placed on the cars by means of eight derricks arranged around a framework, which was maintained at the original ground level. Long piles were driven before the framework was erected to support it as the excavation proceeded, and these piles were braced and spliced as the ground level receded. This feature of the plant was very expensive, as the proper support of this heavy framework kept a large gang of men continually at work. Derricks placed around the edges of the excavation would have proved much more economical, not only on account of needing less maintenance, but also because they would have covered the entire work whereas the derrick frame could not reach the area directly under itself. The derricks were designed without bull wheels so that tag men had to be used throughout. This feature added 6 per cent to the cost of excavation for labor alone, and probably added as much more through loss of time in swinging derricks.

On two sides of the excavation 10 x 12-in. yellow pine sheet piling 30 ft. long was driven to protect sewers, water pipes, etc., in the adjoining streets. The driving was exceedingly difficult and hard, it being through sand and gravel. The piles were often broken in driving and the points of many were found badly broomed when uncovered. The following rates of wages were paid per 10-hour day:

	Per day.
Foreman	\$4.00
Holster	2.50
Fireman	2.00
Carpenter	2.50
Riggers	2.25
Laborers	1.75

The average length of sheet piles was 30 ft.; 8,000 lin. ft. were driven and 9,000 lin. ft. used. The total cost of the sheet piling was as follows, no salvage being credited:

	Total cost.	Cost per lin. ft.
Labor, driving	\$1,405	\$0.176
Labor, bracing	920	0.115
Piles, 90 M at \$20.....	1,800	0.225
Bracing, 100 M at \$13.....	1,300	0.163
Plant	234	0.029
Steam	183	0.016
Total	\$5,792	\$0.724

After the sheeting was driven the excavation was covered down to the required depth of 40 ft. below the elevation of the ground. About one-half the material excavated was sand, and the remain-

der was made up of clay and hard pan. About one-quarter was hard pan and very hard digging. All excavation was done by hand, the material being shoveled into skips, which were then raised by the derricks and placed on flat cars which ran through the derrick frame. The cars were then run to the dump about 400 ft. distant by a cable device, the material being dumped down an incline chute into scows, to be dumped at sea. Building sand, sufficient for all concrete and masonry on this work, was secured from the excavation and stored on the work. The rates of wages paid per 10-hour day were as follows:

	Per day.
Holsters	\$2.75
Signalmen	2.00
Tagman ..	1.50
Trackmen	1.75
Laborers	1.60

The labor cost of excavating 42,000 cu. yds. was as follows:

Labor	Amt.	cu. yd.
Loading skips	\$ 8,000	\$0.19
Loading on cars	2,184	0.05
Dumping	2,879	0.07
General foreman	875	0.02
Total	\$13,938	\$0.33

The total cost of excavation was as follows:

	Quantity cu. yds.	Total cost.	Cost per cu. yd.
Labor	42,000	\$13,938	\$0.332
Pumping	42,000	1,176	.028
Steam	42,000	1,763	.042
Plant ..	42,000	11,140	.265
General expenses.....	42,000	5,585	.133
Dumping at sea	22,000	3,300	.105
Total		\$36,900	\$0.90

The cost of pumping, steam, plant and general expenses were figured for the entire work and distributed through each item separately, as is shown further on. The best month's run constituted 16,351 cu. yds., working 57 ten-hour shifts, which is equivalent to 246 cu. yds. per 10-hour day. The average output for the entire period of excavation was 184 cu. yds. per 10-hour day, which is equivalent to 218 working days for this portion of the work. It will be noted that the plant charges are exceedingly high, and include the sheet piling given above as well as its proportionate charge of derrick frame, trestle, etc.

Foundation Piles.—After the excavation was completed, foundation piles were driven in three clusters under the steel grillages. There were 423 piles in all, and as the bottom consisted of pure sand saturated with water they could not be driven more than an average of 9 ft. below cut-off. The cost of driving these piles is excessive owing to the great difficulty encountered in driving un-

der the derrick frames, which were directly over about 20 per cent of them.

	Total cost.	Cost per pile.
Labor, driving	\$ 731	\$1.73
Piles, 13 ft. long	634	1.50
Pumping	376	0.87
Steam	35	0.08
Plant	213	0.50
General	348	0.83
Total	\$2,337	\$5.50

Timber Grillage.—Over the entire foundation and around the heads of the piles was deposited a 2-ft. layer of concrete in which was imbedded the first course of timber that constituted the grillage, covering the entire area of foundation and consisting of four thicknesses of 12 x 12-in. yellow pine timber. The timber was sized top and bottom and drift bolted every 6 ft. with 1½-in. drift bolts. The top course of timber consisted of alternate rows of 8 x 12 in. and 10 x 12 in. to bond with the concrete. The cost of the timber grillages was as follows, there being 1,394 M ft. B. M. of timber:

	Total Amount.	Per M ft. B. M.
Labor.		
Delivery to anchorage	\$ 1,666	\$ 1.19
Placing	2,437	1.75
Drift bolting	920	0.66
General foreman	490	0.35
Total	\$ 5,507	\$ 3.95
Total cost.	Total Amount.	Per M ft. B. M.
Labor	\$ 5,507	\$ 3.95
Yellow pine	25,090	18.00
Iron	3,900	2.80
Pumping	1,394	1.00
Steam	83	.06
Plant	1,990	1.43
General	3,093	1.60
Total	\$40,056	\$23.74

Concrete.—A layer of concrete varying in thickness from 6 to 10 ft. and covering the entire foundation was deposited above the timber grillage. About 8,200 cu. yds. was required, the mixture being about one part cement to two parts of sand to five parts broken stone. The concrete was mixed in a 2 cu. yd. cubical mixer situated directly beneath the derrick frame, so that the materials could be dumped from cars into the mixer hopper. Broken stone came to the site in barges and was shoveled into skips, and after the required amount of cement was spread on the stone, the skip was lifted by a derrick onto cars situated on the trestle. The car was then hauled by cable to the mixer and dumped, with the required amount of sand for a batch. The mixed concrete was run into buckets and deposited in the work by derricks, where it was

spread and rammed in 12-in. layers. A batch consisted of $2\frac{1}{4}$ barrels of cement, 19 cu. ft. of sand and 47 cu. ft. of broken stone and made 1.8 cu. yd. in place. The maximum output for 10 hours was 111 batches or 200 cu. yds.; the average output for the entire time of concreting, or 57 days, was 68 batches, or 122 cu. yds.

The average force was 51 men divided as follows: 15 hauling materials, 12 placing, 3 mixing; the rest were holsters, runners, signal men, car men, etc. The rates of pay were the same as those previously given. The cost of 8,169 cu. yds. of concrete was as follows:

Labor.	Total.	Per cu. yd.
Handling materials	\$ 2,660	\$0.32
Mixing	348	0.04
Placing	3,003	0.38
General foreman	512	0.06
Total	\$ 6,523	\$0.80
Total cost.		
Labor	\$ 6,523	\$0.80
Cement, at \$1.50 per bbl.....	15,930	1.95
Sand, at \$0.50 per cu. yd.....	1,630	0.20
Stone, at \$1.25 per cu. yd.....	9,800	1.20
Pumping	1,553	0.19
Steam	490	0.06
Plant	4,495	0.55
General expenses	2,460	0.30
Total	\$42,881	\$5.25

The concrete was of large mass and was easily placed. The plant was well designed and the job well managed. The plant charge of 55 cts. per cu. yd. was high; one-half of it was chargeable to the derrick frame. This part of the plant, as before stated, was expensive to maintain and the proportion chargeable to concrete was therefore large.

Masonry.—The stone masonry, consisting of a total of 44,000 cu. yds., was for the most part in large masses; at the same time the tunnels for the anchor chains and the various wells required a good deal of careful setting. The masonry from the concrete up to about ground level consisted of a face of rock-faced limestone with limestone backing. At the ground level came several courses of six-cut granite facing 16 ft. in height, above this came rock-faced granite facing up to the coping courses, which were of six-cut granite. All backing was of limestone, roughly squared, in thickness equal to the face stones of the same course and with vertical joints that averaged 3 ins. The vertical and horizontal joints of all rock-faced ashlar was $\frac{1}{2}$ in.; for six-cut work it was $\frac{1}{4}$ in.

The stone was unloaded from barges at the dock onto cars, which were hauled by cable to the site of the work. The mortar was mixed by machine in the concrete mixer.

The cost of labor in setting masonry was high and was due to the design of the derrick frames, which were directly over the work. They had to be jacked up for each course above the ground level, which was expensive, and being located over the center of

this work, setting stone beneath them was difficult and costly. Tag-men were used to swing the derricks; as the design did not permit bull wheels; they added 15 cts. per cu. yd. to the cost of setting. Stone masons worked an 8-hour day, all other labor a 10-hour day. The labor rates were as follows:

	Per day.
Foreman	\$5.00
Masons	3.20
Signal men	2.00
Laborers	1.50

The total labor cost of setting 44,053 cu. yds. of masonry was:

	Total.	Per cu. yd.
Delivering stone	\$ 9,935	\$0.23
Mixing and delivering mortar...	8,792	0.20
Delivering spalls	965	0.02
Setting stone	41,141	0.94
Total	\$60,833	\$1.39

In the following cost of the various kinds of masonry, the labor was taken at \$1.39 per cu. yd., as above given; there was no means of obtaining the cost of setting the various classes of masonry. Likewise the percentage of mortar was taken at a fixed percentage of the total masonry. Actually the mortar varied from 15 per cent in backing to 6 per cent in rock facing, to 3 per cent in six-cut work. The difference in cost of mortar, however, is more than balanced by the extra cost of setting the facing and six-cut masonry. The cost of mortar per cu. yd. of masonry was:

	Per cu. yd.
0.4 bbl. cement at \$1.50.....	\$0.60
0.12 cu. yd. sand at \$0.50.....	0.06
	\$0.66

The cost of limestone backing 34,200 cu. yds. was:

	Total.	Per cu. yd.
Labor	\$ 47,538	\$1.39
Mortar	22,572	0.66
Stone, \$5 at 85%.....	145,350	4.25
Steam	4,788	.14
Plant	26,340	.77
General expenses	16,760	.49
	\$263,348	\$7.70

The cost of limestone facing 3,500 cu. yds. was:

	Total.	Per cu. yd.
Labor	\$ 4,860	\$1.39
Mortar	2,310	.66
Stone, \$7.25 at 84%.....	23,806	6.80
Steam	490	.14
Plant	2,695	.77
General expenses	1,715	.49
	\$35,875	\$10.25

The cost of granite facing 3,523 cu. yds. was:

	Total.	Per cu. yd.
Labor	\$ 4,900	\$ 1.39
Mortar	2,325	.66
Stone, \$16.66 at 95%	55,170	15.66
Steam	494	.14
Plant	2,715	.77
General expenses	1,730	.49
Total	\$67,334	\$19.11

The cost of granite backing 700 cu. yds. was:

	Total.	Per cu. yd.
Labor	\$ 973	\$ 1.39
Mortar	462	.66
Stone, \$14.47 at 88%	8,925	12.75
Steam	98	.14
Plant	639	.77
General expenses	343	.49
Total	\$11,340	\$16.20

The granite knuckle stone, 300 cu. yds., cost:

	Per cu. yd.
Labor	\$ 1.39
Mortar66
Stone	17.58
Steam14
Plant77
General expenses49
Total	\$20.47

The six-cut granite, 1,640 cu. yds., cost:

	Per cu. yd.
Labor	\$ 1.39
Mortar66
Stone, \$28.67 at 98%	18.05
Steam14
Plant77
General expenses49
Total	\$31.50

Cost of Erecting Steel.—The steel work consisted of a heavy grillage made up of beams 5 ft. 6 ins. deep by 36 ft. and 24 ft. long, riveted together to form an anchorage for each set of anchor chains, and of four chains made up of 2-in. eye-bars from 10 to 14 ft. long. Each chain extended from the top to the bottom of the anchorage and was made up of two rows of 20 eye-bars and fastened together with 6-in. steel pins. The steel was delivered in the same manner as the other materials and set in place by derricks. Each pin rested on a heavy casting or steel girder, which rested upon knuckle stones, cut to the proper angles and set in the masonry. The joints between the knuckle stone and the

bearing girders were rust joints. The total weight erected was 1,583 tons, and the cost of erection was as follows:

Labor:

Delivery and erection.....	\$3,337	
Riveting	1,384	
Painting	962	
Drilling for bolts	349	
Rust joints	282	
Foremen	675	
<hr/>		
Total labor	\$6,989	—\$4.42 per ton
Steel		65.00 per ton
Plant		2.06 per ton
Steam06 per ton
General expenses44 per ton
<hr/>		
Total		\$71.98 per ton

Steam Production.—The cost of fuel and labor for steam production for the whole work is as follows. The boiler battery consisted of four old Manhattan Elevated locomotive boilers of 30 hp. each. They were located near the dock and the steam was piped to the anchorage.

Foreman, day, 25½ mos. at \$85....	\$2,170	
Foreman, night, 25½ mos. at \$60..	1,530	
Helper, 25½ mos. at \$40.....	1,020	
		<hr/>
		\$ 4,720
2,340 long tons soft coal at \$2.25....	\$5,260	
1,525 long tons hard coal at \$4.00..	6,100	
		<hr/>
		\$11,360
		<hr/>
		\$16,080

This cost has been distributed through the different classes of work

Pumping.—Pumping was done during part of the time that excavation, pile driving, concreting and timber grillage work was being done, a total of 235 days. The cost was as follows:

Engineers, 466½ days at \$2.85.....	\$1,330	
Laborers, 202½ days at \$1.50.....	303	
		<hr/>
Total	\$1,633	
Steam	2,964	
Plant	990	
		<hr/>
Total cost		\$6,587

Plant.—The plant cost for the various kinds of plant and machinery described under the different classes of work were as follows; no salvage has been credited:

	Materials.	Labor.	Total.
2 Derrick frames, complete.....	\$ 8,538	\$ 8,052	\$16,590
2 Derrick frames, repairs.....	8,321	11,574	19,895
Trestle and track	4,117	1,626	5,743
Boiler, battery	1,140	134	1,274
Pumping	990	268	1,258
Pile driver	2,590	2,590
Mixer and trestle	612	426	1,038
2 Derricks at bulkhead	2,321	448	2,769
1 Howe truss.....	480	517	997
1 Derrick for sand.....	703	52	755
Sewer	120	158	278
Gutter	35	28	63
Electric light	2,000	2,000
Water for motor	500	500
Water for steam	1,280	1,280
Waterproofing	260	260
Total	\$32,817	\$24,563	\$58,380

General Expenses.—The general expenses were made up as follows:

Office force and watchman, 21 mos., at \$922.50....	\$19,395
Making bid, say	500
Money invested, say \$50,000, at 5%, for 21 mos..	4,400
Bond, \$350,000, at 1%.....	6,125
Insurance, \$140,000, at 3%.....	2,800
Travelling expenses, say	500
Office rent	1,825
Building office and storeroom	800
Office fixtures	400
Office stationery, telephone, etc.....	1,000

Total \$37,745

Labor Cost of the Foundations of City Island Bridge, New York.*
Before giving the figures of the cost of labor in the construction of the foundations of the City Island Bridge, it will be well to give a brief description of the bridge itself. The City Island Bridge connects City Island and Pelham Bay Park at Rodman Neck, Bronx Borough, New York. It is about 1,500 ft. long, including approaches, and 50 ft. wide over all. There are six masonry piers and two abutments, all sunk to rock or hard material at a maximum depth of 40 ft. below high water, and they support the steel superstructure. The superstructure proper consists of a 180-ft. draw span and five 80-ft. spans. The pivot pier, which has a maximum diameter of 35 ft., is protected by a longitudinal crib, 228 ft. long and 51 ft. wide. The pier has 45 degree cutwater ends and is sheathed with 4-in. yellow pine vertical planks, 14 ft. long, which extend from 1 ft. below mean water level to the top of the crib, 5 ft. above mean high water. The pivot pier occupies a rectangular space, 63 ft. long and 37 ft. wide. The bridge was built for the Department of Bridges, New York City, the superstructure being

constructed by the King Bridge Co., and the substructure by John F. O'Rourke.

Cofferdams.—A subcontract for the construction of the cofferdams was let by John F. O'Rourke, the contractor for the foundations, to Warren Roosevelt, New York. The material used was yellow pine. The lower sections of the cofferdams, which remained in the permanent work, were constructed upon ways and launched. The upper section was then constructed. Several pile driving scows were used on the work. In the placing of the cofferdams, the plant was furnished by Mr. Roosevelt; but Mr. O'Rourke furnished the laborers for loading bags of gravel to sink and place them. In the summary, Table XV, which gives the time for constructing the cofferdams and the amount of material used, it will be noticed that the dam for abutment No. 1 was constructed in a less period than any of the others. This was due in a measure to better facilities for handling the material. The higher cost for building the cofferdam for Pier No. 3 (pivot pier) was due to the fact that it was built in an octagonal form. No data were obtained of the cost of setting the cofferdam for pier No. 3.

Masonry.—According to the specifications, the masonry was classified in two grades: (1) Foundation masonry and (2) pier masonry. Blue gray limestone, or other dark stone of compact granular structure without lamination, was to be used in both cases. The backing of the abutment masonry, to mean high water, was to be concrete in the proportion of 1 : 2 : 4. Above mean high water the proportion of concrete was to be 1 : 3 : 5. The foundation masonry was to be laid to the elevation of mean low water, and was to consist of first-class quarry-faced ashlar bedded in Portland cement mortar with $\frac{1}{4}$ -in. joints, and well rammed concrete backing of 1 : 2 : 4 concrete. Work was to be laid in regular courses, 24 in. to 30 in. in depth, with thickness progressively diminishing upward. All stones were to be cut to line on their natural beds, and the top surface had to be parallel with its bed. Beds were to be dressed the entire width of the stone and vertical joints cut back not less than 12 in. Courses were to break joints with each other at least 12 in., and headers were to be arranged so as to come over underlying stretchers. Not less than one header to every two stretchers was to be used. The concrete backing was to be leveled up with each course of stone. The stones for the pier masonry were to be cut to dimension, and laid with joints not exceeding $\frac{1}{2}$ in. The hearting or backing was to consist of 1 : 2 : 4 concrete for abutment to elevation of mean high water; 1 : 3 : 5 concrete was to be used above that elevation. The coping was to consist of selected limestone or light colored granite, quarry faced, laid with $\frac{1}{4}$ -in. joints.

As a matter of fact, the stone used for the masonry was Cobble-skill limestone facing with concrete backing. The coping was granite from Maine. The masonry work was done by John F. O'Rourke, the contractor. The plant consisted of two derrick scows and stiff leg derrick, the latter being used on abutment No. 1 and pier No. 3. One of the scows was used mainly in depositing concrete

backing The foregoing table of cost for masonry work is for building the masonry after the material was loaded on the scows, and does not include the handling of material, placing stone from yard on scows and cement from the storehouse.

The higher cost of the construction of masonry of pier No. 2 and pier No. 4 will be explained by an examination of the Summary Table, which shows the proportion of backing and face stones.

Granite Cutting.—In this work the material was furnished by Mr. O'Rourke, but the labor was done by a sub-contractor. The granite was brought by vessel from Maine and was used in coping, bridge seats and abutment steps. Beds were peenhammered and the faces rock faced. A total of 7,052 cu. ft. was cut. Eight hours constituted a day's work.

In the table below is given the labor cost of cutting the granite

TOTAL COST OF CUTTING GRANITE.—(7,052 CU. FT.)

SUMMARY.

Abutment No. 1..	Abutment No. 2..	Abutment No. 3..	Abutment No. 4..	Depths in Feet	Began 1899.	Finished 1899.	Cu. Yds. Concrete.
...	18	Oct. 2	Oct. 19	887.63
...	30	Aug. 21	Oct. 3	344.73
...	34	Aug. 28	Aug. 30	324.01
...	36	July 31	Aug. 9	942.62

were used. The mixing was done by a rectangular horizontal machine mixer. The concrete was deposited continuously, working day and night, except in the case of pier No. 2, where an accident to the cofferdam sides caused an interval of several weeks.

Table XVII of costs for cleaning and repairing is for the work of the diver in removing with hoes, shovels and pumps the silt which had been deposited on the foundation site. The foundations had been cleaned by the dredge several months before, the work of the diver being to remove the silt which had afterwards been deposited. There was much soft material in abutment No. 1, owing to the proximity of the embankment. At pier No. 3 the cofferdam rested upon a rock, which had to be drilled and blasted. Little work was required at pier No. 4, as the site was comparatively clean. In the table for concreting, the high cost of the work on pier No. 2 was due to the fact that the concrete was improperly deposited and had to be removed. In the same table, the higher cost for the work under abutment No. 1, was probably due to the fact that the abutment was so long and narrow that it was difficult to handle the bucket.

Weight and Cost of the Washington Bridge, N. Y. City.*—In his book entitled "The Washington Bridge," Mr. William R. Hutton gives the following data:

The Washington bridge, across the Harlem River, was built in 1886-1888 by contract. It consists of two steel arch spans of 510 ft. each, and six masonry arch approach spans of 60 ft. each. The width of the carriage way is 50 ft., and each of the two sidewalks is 15 ft. wide. The rise of the steel arches is 92 ft., the spring line being 41 ft. above M. H. W. The center pier rests on a caisson sunk 40 ft. below M. H. W. The other two main piers required no caisson work. The masonry of these three main piers was carried up to the floor level of the bridge. The main piers are 40 ft. thick at the spring line and 98 ft. long. They are of concrete, faced with granite. Above the stone back they are cellular. The total length of the bridge between abutments is 1,550 ft. In addition to this there are approaches, consisting of embankments supported by retaining walls, at each end of the bridge.

The two steel arches required 1,500,000 ft. B. M. timber for the falsework (one span rested on piles), and the six masonry arches required 1,500,000 ft. B. M., including timber used in trestles for landing materials. Each of the steel arches consists of 6 steel ribs of 13 ft. deep.

The superstructure of each 510 ft. long weighs 13,086 lbs. per ft. of span, and is designed for a live load of 8,000 lbs. per ft. of span. The cost of this bridge was:

Paid to contractors.....	\$2,648,785
Engineering, etc.	162,400
Commissioners' office	40,500
Total	\$2,851,685

**Engineering-Contracting*, July 14, 1909.

This is equivalent to \$23 per sq. ft. of roadway between the abutments. Some of the principal quantities and cost were as follows:

8,368 cu. yds. granite in piers (dressed).....	\$203,101
2,300 cu. yds. cornice and parapet.....	201,246
16,491 cu. yds. arch voussoirs.....	248,293
16,545 cu. yds. facing.....	174,762
29,348 cu. yds. granite concrete.....	161,052
21,319 cu. yds. earth excavation.....	80,048
26,504 cu. yds. rock.....	29,211
12,815 cu. yds. embankment.....	7,538
4,052 cu. yds. caisson.....	182,354
151,078 sq. ft. flagging (sidewalk).....	49,577
18,742 sq. yds. asphalt roadway.....	62,782
7,549,606 lbs. steel in arch ribs and bracing.....	777,259
5,927,816 lbs. iron in posts, bracing and floor.....	777,259
1,232,874 lbs. cast and wet iron in cornice and balustrade	132,260

The caisson foundation of the center pier contained 7,726 cu. yds. of timber and concrete for the 40½ ft. below the highwater line, which cost the city \$30.64 per cu. yd.

The contractor paid the following wages: Laborers, \$1.75; masons and stone cutters, \$2.50; drillers, \$2; enginemen, \$2.50; carpenters, \$3; painters, \$1.75.

Portland cement was substituted for Rosendale for about 40 per cent of the amount of cement used, adding \$32,000 to the cost above given.

Cost of a Bridge Foundation Excavation and Cofferdam.—Mr. Walter N. Frickstad gives the following data on bridge foundation work, done by force account, by the Southern Pacific R. R. in Nevada, year 1902-3. In crossing the Humboldt River the line made a very sharp angle with the river, but a skew bridge was not used. There were two abutments and one pier. To build the east abutment an L-shaped cofferdam of sand bags, filled in between with earth, was used. The long leg of the L was 100 ft. long, and the short leg 40 ft. long. This enclosed a triangle of water, bounded by the two legs of the L-shaped cofferdam and the shore line of the river. The sand filled sacks were wheeled to place and deposited by men provided with long-handled shovels and sticks to guide them to place; but it was not found practicable to build the sacks up in tiers, for the air spaces in the sacks buoyed them so that they were easily displaced by the river current. It was intended to leave a 3-ft. space between two tiers of sacks, to be filled with puddle, but this space became choked with sacks. It was found impossible to pump out this dam with a one-man sewer "deluge" pump, so a bank of earth was deposited outside of the dam of sacks. Where the current was swiftest, the earth was rushed to place with a steady stream of wheelbarrows, the coarsest gravel being used as a riprap on the loam and sand; and, in spite of current of 5 ft. per second, the embankment held its place. Then with 4 men on a shift, two working while two rested alternately in 15-minute periods, the dam was pumped dry in 2 days and 3 nights, at a cost of \$19 per 24 hrs. To reduce the area, to be kept pumped out, a cross-wall of sacks, 30 ft. long, was put in. About 2,230 sacks were used, all told.

This work cost as follows:

Building L-shaped dam, 53 days, at \$1.50.....	\$ 79.50
Filling its slope with earth, 32 days, at \$1.50.....	48.00
Building cross-wall of dam, 30 days, at \$1.50.....	45.00
Excavating mud and loose rock, 24 days, at \$1.50..	36.00
Pumping until masons were above water line, 85 days, at \$1.50.....	127.50
Foreman, 9 days, at \$3.....	27.00

Total\$363.00

While the masons were at work on the east abutment the coffer dam of the center pier was built in a manner that proved to be the cheapest and requiring the least equipment of all the methods of cofferdamming used. To get to bed rock there were 2 ft. of silt, 7 ft. of gravel and boulders and 5 ft. of boulders. Tests with long drills had led the engineers to believe that solid rock was 5 ft. nearer the surface, the boulders being mistaken for solid rock. The pier was of masonry with a sharp nose at each end, so the cofferdam was made of similar shape and with a length of 55 ft.

Fig. 9.—Plan of Cofferdam.

from nose to nose, and an outside width of 16 ft. The cofferdam consisted of sheet piling driven by hand as fast as the excavation progressed inside, just as in ordinary sheeting of a sewer trench. The rangers, or waling pieces, to support the sheet piling were made of 8x17-in. Oregon pine, drift-bolted together to form a frame, as shown in Fig. 9. This frame was laid flat just above the surface of the water, being temporarily supported by a bar of river sand at one end and by a pair of wooden horses (4 ft. high) near the other end. These horses were built and sunk in the stream, and planks laid out from the sand bar, upon which to push the frame to place on 1½-in. gas pipe rollers by four men using pinch bars. About one-third of the frame overhung these horses, and the water was 7 ft. deep at the outer nose of the frame. Holes were dug 2 ft. deep under the three corners of the frame that rested on the sand bar, and temporary posts set in these holes to support that end of the frame. Then excavation was begun, 8-ft. lengths of sheet planking or piling being driven, starting at the nose of the frame. A heavy wooden maul was used to drive the sheeting. When 12 of these 3x12-in. sheeting planks had been driven down a short distance, earth and manure were piled outside. Then the lines of sheeting were continued out into the river,

using longer plank. Finally several of the sheeting planks were temporarily spiked to the frame, the horses removed, and plank driven to close the gaps. Earth and manure were banked up outside the sheeting. It was found necessary to deflect the river current, which was washing away this earth and manure, and to do this a wing dam of sacks filled with sand was built, and coarse gravel and sand-filled sacks used to riprap the outer end of the earth and manure fill. The water was readily pumped out, and excavation begun. It was found that the sheeting was sloping inward, so a second frame was built of 6 x 12's inside the excavation and at the bottom of the sheeting; then the driving of the sheeting was continued and this second frame was lowered as the excavation progressed. Once the gravel caved and two sheet planks were forced in, but quick work with brush, manure and earth

Fig. 10.—Section of Cofferdam.

closed the hole. When the excavation was 7 ft. below the water surface, and rock was not encountered, it was decided to build a third frame and drive a second tier of sheet plank inside, and sloping outward, as in Fig. 10. This was begun when the flow of water became so great that a 6-hp. Fairbanks, Morse & Co. combined gasoline engine and pump was installed, and no further difficulty occurred in getting down to bed rock. The cost of this pier excavation by force account was as follows:

Labor excavating, etc., 324 days, at \$1.50.....	\$ 486.00
Labor pumping, 136 days, at \$1.50.....	204.00
Engine-runners, 50 days, at \$3.	150.00
Four-horse team, 6 days, at \$5.....	30.00
Carpenter, 8 days, at \$3.....	24.00
Foreman, 24 days, at \$4.....	96.00
115 gallons gasoline, at 15 cts.....	17.25
300 sacks, at 15 cts.....	45.00
10 M. of pine, at \$30.....	300.00
Total	\$1,358.25
Salvage value of 5 M of pine removed.....	150.00
Total for 280 cu. yds. excavation, at \$4.30...	\$1,208.25

I have assumed the prices and rates of wages as above given, although in fact they may have varied slightly. The number of days' work and the amount of materials is exact. It will be noted that half the timber in the cofferdam was recovered and used elsewhere. The cost of excavation was high, because no derricks were used, but the shoveling was done in stages; moreover, there was a large quantity of boulders, and trouble with pumps caused considerable delay.

The excavation for the west abutment, though much larger than for the pier just described, was done in the same manner. The cofferdam inclosed an L-shaped area, about 50 ft. long on each leg of the L, and about 20 ft. wide. The waling frames were built in place after the site had been excavated to the water level with drag scrapers, and the second and third frames in due course. In lowering the frames from time to time as the excavation progressed, it was found almost impossible to drive them down with a 16-lb. sledge or a wooden maul. Even a 6-in. x 12-in. x 8-ft. wooden rammer, operated by two men, failed to drive the frames. It was found that by loading the shoveling platforms, 2 ft. wide by 16 ft. long, with gravel, one platform being loaded on each side the section to be lowered, a slight tapping produced any desired amount of settling. The excavation was not carried to bed rock, but the abutment was founded on the gravel and boulders, at a depth of 12 ft. below the water surface. The cost of this work was as follows:

Team on drag-scraper, 18 days, at \$3.50.....	\$ 63.00
Laborers, 748 days, at \$1.50.....	1,122.00
Carpenter, 85 days, at \$3.00.....	105.00
Pump engineers, 140 days, at \$3.00.....	420.00
Foreman, 35 days, at \$4.00.....	140.00
45 tons coal, at \$6.00.....	270.00
150 gallons gasoline, at 15 cts.....	225.00
22 M lumber, at \$30.....	660.00
Total	\$3,005.00
Salvage value of 11 M lumber removed.....	330.00
Total, 700 cu. yds., at \$3.82.....	\$2,675.00

Cost of Coffor Dam.*—Maj. Graham D. Fitch gives the following:

A cofferdam was built on the Upper White River, Arkansas, within which to build a lock. Common laborers received \$1.50 per 8-hr. day. The work was done by Government forces.

The lock (No. 1) was founded on sandstone bed rock, and as the foundation bed afforded no foothold for piles, crib cofferdams were used. These were built and sunk in sections from 20 to 30 ft. long, each section consisting of round oak logs 7 to 9 ins. in diameter, driftbolted together with $\frac{1}{2}$ -in. round iron. The walls were tied together every 10 ft. by a transverse crib wall. Above the water the cofferdam was a continuous crib. The inside faces of both walls were sheeted with boards driven to a good bearing with hand mauls, a single row of 1-in. boards being used for the outer wall and double lap 1-in. and 2-in. boards for the inner wall,

**Engineering-Contracting*, May 6, 1908, p. 278.

The pens were filled with clay and the dam well banked on the outside. The puddle, which was taken from a bank nearby, was loaded by a dipper dredge on a barge and placed in the dam with shovels. The inside width of the cofferdam was 10 ft. 8 ins., and its length was 462 ft. It was built to a 9 ft. stage and had an average height of 17 ft. The dam was built in 6 weeks time and the pit was pumped out in about 11 hours with one 10-in. centrifugal pump. A $3\frac{1}{2}$ -in. pulsometer pump was used to keep seep water out of the pit. There was very little leakage except during rises, after which the dam always had to be repuddled, as much of the backing was washed away by the swift current. The cost of this cofferdam was as follows:

COFFERDAM (462 LIN. FT.).

Materials:	Unit Cost.	Total.	Per lin. ft. Cofferdam.
Logs, 30,560 lin. ft.....	\$.0365	\$1,115	\$2.41
Timber, 32.8 M ft. B. M.....	10.90	360	.78
Iron, 8,139 lbs.....	.0289	234	.51
Straw, 12 loads.....	1.75	21	.04
Fuel	177	.38
Illumination, olla, etc.....	104	.22
Total materials	\$2,011	\$4.34
Labor:			
Quarrying and placing break-water stone, 498 cu. yds.....	\$ 0.718	\$ 358	\$.85
Excavation, 300 cu. yds.....	.562	169	.36
Hauling lumber, 20 M ft.....	.86	17	.04
Placing logs, 30,560 lin. ft.....	.02	638	1.38
Placing timber, 32.8 M ft.....	1.73	57	.12
Digging puddle, 7,860 cu. yds..	.062	490	1.06
Placing puddle, 7,860 cu. yds..	.63	4,179	9.05
Pumping pit	539	1.17
Total	\$6,476	\$14.03
Grand total	\$8,487	\$18.37

Some of the labor items may be still further summarized as follows:

	Work done.	Labor time in days.	Work done per man per day.
Quarrying and placing breakwater stone....	498 cu. yds.	248	2 cu. yds.
Excavation	300 cu. yds.	96 $\frac{1}{8}$	3.16 cu. yds.
Placing logs	30,560 lin. ft.	370 $\frac{1}{8}$	82.59 lin. ft.
Placing timber	32.8 M ft.	37 $\frac{4}{8}$.863 M ft.
Placing puddle.....	7,860 cu. yds.	2,392 $\frac{6}{8}$	3,284 cu. yds.

The total labor time in constructing the 462 lin. ft. of cofferdam was 3,660 $\frac{1}{8}$ days. The unit cost per linear foot of cofferdam was \$18.37 and the work done per man per day was .126 lin. ft. About 90 lin. ft. of cofferdam was removed by dredge and men, at a cost of \$161; the labor time being 86 $\frac{1}{8}$ days. The unit cost was \$1.794 per lin. ft.

In excavating for the foundation of the lock a $1\frac{1}{4}$ cu. yd. Bucyrus dipper dredge removed from the pit, before the cofferdam was closed, such material as it could handle; but owing to the large boulders encountered most of the excavating was done by hand after the cofferdam had been pumped out, the material—clay, boulders, and cemented gravel—being removed by wheelbarrows and derrick skips. The lockwall foundations averaged 6 ft. in depth below the lock floor, the maximum depth being 8 ft. 5 ins. Both the chamber and miter wall were founded on bed rock.

The cost of excavation work was as follows:

EXCAVATION (3,635 Cu. Yds.).			
	Unit		Per cu. yd.
Material:	Cost.	Total.	Excavation.
Dynamite, 600 lbs.....	\$0.14	\$ 84	\$0.023
Fuel		9	.002
Illuminating oils, etc.....		119	.022
Total materials		\$ 212	\$0.057
Labor:			
Excavating, 3,365 cu. yds.....	\$1.49	\$5,438	\$1.49
Cleaning lock pit.....		108	.029
Total labor		\$5,546	\$1.519
Grand total		\$5,758	\$1.58

The total labor time in days for excavating was 3,138 $\frac{1}{4}$ days and the work done per man per day was 1.16 cu. yds.

Cost of Placing Puddle in a Cofferdam by Pumping.*—Mr. William Martin is authority for the following data:

In building Davis Island Dam, several years ago, a cofferdam 1,085 ft. long, containing 5,784 cu. yds. of puddle material, was built by pumping the puddle from an island. The cofferdam consisted of two rows of piles, the rows being 15 $\frac{1}{2}$ ft. c. to c. and the piles in each row being 21 ft. c. to c. The piles were 20 ft. long, and were driven 8 ft. Three rows of wale pieces or stringers were bolted to the piles, 12 ft. apart. A single line of vertical sheeting plank, driven 2 ft. into the gravel bottom, rested against the wales. The joints of the sheeting were covered with 1x6 in. strips to prevent leakage of the puddle. On each side of the sheeting, at the top, was spiked a 2 x 10 in. string piece, to form a bearing upon which a plank deck was laid.

The plant, as finally developed, was as follows:

Tubular boiler, 36 ins. diam x 16 ft. long.

Engine, 10 x 10 ins.

Piston pump—steam cyl. 12 x 18 ins.; water cyl. 4 $\frac{1}{2}$ x 18 ins.

Centrifugal pump, 3 in. discharges.

Pipes, etc., of the following sizes were used: Delivery pipe, 4-in.; clearing pipe, 2 $\frac{1}{2}$ -in.; priming pipe, 1 $\frac{1}{2}$ -in.; lubricator pipe, 1-in.; steam pipe to engine, 2 $\frac{1}{2}$ -in.; steam pipe to piston pump, 2-in.; hand wheel on engine shaft, 4 $\frac{1}{2}$ ft.; pulley on centrifugal pump shaft, 10 ins.; width of driving belt, 10 ins.; agitator hose, 1 $\frac{1}{2}$ ins.

*Engineering-Contracting, Jan. 6, 1909.

The following pressures were obtained: Steam boiler, 100 lbs. per sq. in.; gage on piston pump, 70 lbs.; gage on delivery pipe, 25 lbs.

The centrifugal pump for pumping the puddle was located on an island 900 ft. from the cofferdam. Beneath the pump was a tank for mixing the puddle, 8 ft. diameter and 4 ft. deep, sunk to a sufficient depth to secure a fall of water from a flume that tapped the river.

The piston pump was connected to the delivery pipe by a wye connection, and was used for priming the centrifugal pump, and keeping the sand from packing, and for furnishing water for the steam boiler and for the agitator hose, as hereafter described.

The puddle, consisting of loam and sand, was obtained within a radius of 100 ft. from the pump by loosening with a plow and delivering close to the tank with drag scrapers. It was then shoveled by hand into the tank, a cost that could have been avoided had the scrapers dumped through a trap into the tank. The material was mixed with water in the tank and kept agitated by water from a hose in the hands of workmen, to prevent the earth from settling to the bottom. This puddle was taken by the feed pipe of the centrifugal pump and forced through the delivery pipe to the cofferdam, a distance constantly increasing as the work progressed. The delivery pipe was laid on the bottom of the river, and then rose by an easy ascent to about 1 ft. above the top of the cofferdam.

The puddle occasionally became so thick as to clog the delivery pipe. In order to meet this difficulty, the following ingenious plan was devised. On the delivery pipe at the centrifugal pump was placed a pressure gage. Any clogging of the delivery pipe immediately caused the pressure to rise, whereupon the engineman slackened the speed of the centrifugal and opened the valve in the wye connection to the piston pump. This admitted a stream of clear water at high pressure from the piston pump and immediately cleared the congestion of puddle in the delivery pipe. The check valve in the delivery pipe between the wye connection and the centrifugal pump prevented a back flow into the centrifugal pump.

At the bottom of the feed pipe in the tank was a screen having 1-in. meshes. Above the screen, and in the same casing, was placed a foot valve for the purpose of holding the priming.

One of the principal difficulties in working the centrifugal pump was the rapid wear of all its parts that came in contact with the sand. The casing, which was originally $\frac{3}{4}$ -in. thick, wore through in 10 days, during which time not 2,500 cu. yds. of puddle were handled. This was replaced with a 1-in. casing which was still in service after the 12 days use which completed the job.

The stuffing box wore rapidly until the following ingenious device was applied. A screw was cut in the chamber in the opposite direction to the motion of the shaft. A pipe was put in back of the packing and connected with the piston pump. Water was forced through this around the shaft, and, being under a greater pressure than the centrifugal pump, prevented the puddle material from getting into the stuffing box. Water thus applied performed a

double duty, for it acted as a lubrication and prevented the shaft from heating.

At the discharge end of the delivery pipe the puddle material was deposited in the cofferdam and flowed off for a distance of a few hundred feet, depositing in a hard and solid mass. The loam being lighter, remained longer in suspension and settled out on top of the sand.

In 23 days there were delivered 5,784 cu. yds. of puddle material, or 251 cu. yds. per 10-hr. day. Laborers received \$1.75 to \$2 a day, and mechanics \$2.50 to \$2.75. The cost was as follows:

Plant:

Pump	\$ 145
Repairs, fittings, etc.....	382
Pipe	364

Total cost of plant.....\$ 891

Labor:

Installing plant and pumping puddle, removing
plant, etc.....\$2,847

Fuel:

23 days fuel.....\$ 38

Total labor and fuel.....\$2,885

It will thus be seen that the cost of labor and fuel for puddling amounted to \$265 per lin. ft. of cofferdam, or 50 cts. per cu. yd., including the labor cost of installing the plant. It is unfortunate that this item of installation and removal of plant was not kept separate, as it was evidently a large item. The fuel cost only \$1.55 a day, or $\frac{1}{2}$ ct. per cu. yd. The labor during the 23 days of pumping could probably not have exceeded 4 cts. per cu. yd. for pumping and pipe laying. With a haul averaging about 50 or 60 ft. for the drag scrapers, the cost of delivering the puddle alongside the tank probably did not exceed 10 cts. per cu. yd. Shoveling it into the tank doubtless cost less than 10 cts. per cu. yd. This would make a total of not more than 25 cts. per cu. yd. for the puddle in place, exclusive of plant charges for interest, depreciation, repairs and installation. Apparently the installation and removal of the pumping plant cost at least \$1,500. The plant itself cost \$891, as above given. The exceptionally high cost of installation appears to have been due in part to the experimenting incident to developing the best way of handling the material, most of which cost can be saved by studying the finally adopted methods and devices above given.

For comparative purposes it is well to add the following costs of filling another section of another cofferdam nearby by another method. The other section was 1,165 ft. long, and it cost \$5.69 per lin. ft. for puddle in place, or practically \$1.10 per cu. yd. of puddle. The method employed consisted in loading the material by hand into cars, hauling it over a narrow gage track to the river, loading into boats and transporting to the cofferdam, shoveling by hand into place, and compacting with water. Wages were only \$1.25 a day for laborers, and \$2.25 for mechanics.

The Cost of Some Masonry Bridge Piers and Abutments.*—Some fairly complete data as to the cost of constructing bridge masonry are given below. The work, which was done by contract for the Chicago & West Michigan Ry., consisted of the construction of a pier and abutment at New Buffalo, Ind., to carry the tracks of the above road over the Michigan Central R. R. Work was commenced Aug. 24, 1891, and was finished Oct. 27, 1891, taking in all 56 working days.

The average working force and its wages per day were as follows:

1 Foreman	\$2.50
1 Engineman	2.00
4 Stonecutters	3.00
1 Mason	2.50
9 Laborers	1.50

From this it will be seen that the total labor cost per day was \$32.50, and the total cost for 56 days was \$1,825.

The cost of the labor was distributed as follows:

	Cu. yds.	Cost.	Cost per cu. yd.
Excavating, abutment.....	868	\$123	\$0.153
Excavating pier.....	232	45	0.194
Cutting stone, abutment....	281	514	1.93
Cutting stone, pier.....	163	347	2.13
Setting stone, abutment....	281	197	0.70
Setting stone, pier.....	163	152	0.93
Unloading stone from cars..	444	50	0.11

To the above should be added \$86.50 as the cost of erecting and moving the plant.

The total cost of the work to the contractor amounted to \$1,863, as is shown by the following figures:

Labor	\$1,825.00
78 bbls. Louisville and Miller cement....	78.00
8 bbls. Buckeye cement.....	30.00
40 yds. sand.....	30.00
10% of value of plant.....	200.00
Total	\$1,863.00

According to the estimate on which the contractor was paid he was to receive \$6.50 per cu. yd. for masonry cut and placed, and \$0.25 per cu. yd. for excavation. As 444 cu. yds. of masonry were constructed and 1,100 cu. yds. of earth excavated, the contractor received \$3,148.50. His total expenses, as shown in the preceding paragraphs, were \$1,863; therefore he made a profit of \$1,285.50 on the job.

The total cost of the Chicago & West Michigan Ry. was \$5,834.65; this includes the estimate of \$3,148.50 and the furnishing of 435 cu. yds. of stone, costing \$6.29 per cu. yd.

The stone used was Grafton sandstone delivered on cars at La Porte, Ind. It should also be added that the amount given for

**Engineering-Contracting*, May 30, 1906.

use of plant covered the expense of repairing stonemasons' tools and the cost of fuel.

Cost of a Masonry Bridge Abutment.*—We give herewith the cost of constructing the west abutment of a 60-ft. through girder bridge near Ionia, Mich., where the Detroit, Lansing & Northern R. R. crosses Prison Road. The work was done by contract for the above-mentioned railroad. According to the terms of the contract the railroad company furnished the stone and free transportation of men and materials, the contractor furnished all other material and labor, and in addition was paid for all timber left in the construction. His plant consisted of a steam hoist derrick with accompanying tools, etc. The stone used was sandstone from Grafton, O., and was delivered f. o. b. Detroit. The average weight of a carload of stone was 33,873 lbs., and the average carload contained 203 cu. ft. The average weight per cubic foot, according to car weights and quarry measurements, was 166.8 lbs. Hanover Portland cement was used, and on account of the low temperature when the work was done, it was necessary to add salt to the mortar. In the excavation, the removal of excavated matter was done almost entirely with wheelbarrows. The excavated material was sand and was wasted. The overhaul was only a short distance, the lead being but 75 ft. The work of excavating was commenced November 18, 1893, the first stone was laid December 5, and the last stone January 7, 1894; two days later the contractor finished removing his plant. As will be seen from the above dates, the work was done in the winter, and this accounts in a measure for the higher cost of stonemasonry, etc. Indeed, it was necessary to use heated sand to remove the frost from the stone before it was cut.

The tables below give the actual cost of materials and labor to the contractor:

MATERIALS.

24½ bbls. Hanover Portland cement at \$2.85.....	\$ 98.32
24 wagon loads sand at \$0.75.....	18.00
2 bbls. salt at \$1.00.....	2.00
Coal for engine.....	20.00
2 cords wood (heating sand).....	3.50
Total	\$141.83

Derrickman	3.6 " " 1.50	5.40
Total, 380 cu. yds. at \$0.23.....		\$86.23

The total labor cost to the contractor was \$952.38, to this must be added \$120.00 for depreciation and repairs to plant, and \$141.83 for the cost of materials, thus making the total cost to the contractor for material and labor amount to \$1,214.21.

The final estimate of work done by the contractor and the unit rate at which he was paid for it, were as follows:

772 cu. yds. excavation at.....	\$0.25
380 cu. yds. backfilling at.....	0.25
181.7 cu. yds. masonry, cut and place at.....	6.15
16 cu. yds. masonry (retaining wall) at.....	4.00
30.5 cu. yds. old masonry taken down at.....	0.30
Total paid to contractor, \$1,478.73.	

As was shown in the preceding paragraph the total actual cost of the work to the contractor was \$1,214.21. His profit accordingly amounted to \$264.52 or 21.8 per cent.

Fig. 11.

The cost to the Detroit, Lansing & Northern R. R. was as follows:

165 6 cu. yds. Grafton standstone at \$6.021, \$997.22; amount paid contractor, \$1,478.73; total, \$2,475.95.

The cost per cubic yard of masonry to the railroad company was as follows:

181.72 cu. yds. of stone (wall measurement), total cost, \$997.22; per cubic yard, \$5.48; 181.72 cu. yds. of stone cut and placed, cost \$6.15 per cu. yd.; total cost per cubic yard of masonry is therefore \$11.637.

Labor Cost of a Bridge Abutment.*—The work was done by contract during the fall of 1893 for the Detroit, Lansing & Northern R. R., near Redford, Mich. Figure 11 shows plan of the abutment. According to the terms of the contract, the railroad company furnished the stone and free transportation of men and materials, and the contractor furnished all other material and labor, and in addi-

**Engineering-Contracting*, June 6, 1906.

tion was paid for all timber left in the construction. The stone used was sandstone from Grafton, O., delivered f. o. b. Detroit, Mich. The average weight of the stone per carload was 41,900 lbs.; the average number of cubic feet per carload was 243. The average weight of a cubic foot of the stone as amputated from the car weights and quarry measurements was 174.4 lbs. It should be noted, however, that the true dimensions of the stone were considerably larger than the quarry measurements, and this accounts for the apparent large weight per cubic foot.

Buffalo natural cement was used in the greater part of the work, but Dyckerhoff Portland cement was used for pointing and for joints in the face of the work as far as 10 in. back from the face. The sand was obtained from the property of the railroad company, the only cost to the contractor being for the loading and unloading. The material excavated was sand and clay, and was removed from the excavation by wheelbarrows and by boxes holding about 1½ cu. yds., which were lifted out by the derrick. The greater part of the excavated material was removed by the latter method.

The contractor's plant consisted of a steam hoist derrick and a hand derrick. For driving the sheet piling a small man-power driver was constructed. This was built with an oak driver weighing 125 lbs., and having a drop of about 4 ft. The sheet piling was double and triple 1 in. x 12 in. oak, 16 ft. long, and was driven 8 ft. through clay and coarse gravel. The contractor began erecting his plant September 7, 1893. On September 11 excavation was started, and October 2 the first stone was laid; the last stone was laid November 19, and one week later the contractor finished removing his plant.

Foreman	4.3 days at \$2.50	\$10.75
Laborers	33.2 " " 1.50	49.80

Total, 90.4 cu. yds. at \$0.67..... \$60.53

Of the 1,632 cu. yds. of earth excavation there were 1,260 cu. yds. dry, and 372 cu. yds. wet. The dry excavation cost \$253.08, or 20.8 cts. per cu. yd. The labor of the wet excavation cost \$85.75, or 23 cts. per cu. yd., to which must be added nearly 3 cts. for pumping and 73 cts. for the labor of driving the sheet piles, including the labor of making the pile driver. This makes a total of 99 cts. per cu. yd. for the labor of the wet excavation; but in addition to this there was nearly 9,000 ft. B. M. of oak sheet piling, which at \$14 per M (a very low price), would add another \$180, or nearly 34 cts. per cu. yd., making the total cost nearly \$1.33 per cu. yd. for the 372 cu. yds. of wet excavation. Had the sheet piling timber cost \$20 per M, the total cost of the wet excavation would have been about \$1.50 per cu. yd.

The total labor cost to the contractor was \$2,552.02. To this amount must be added the following:

10% value of plant for depreciation and repairs.....	\$140.99
8,932 ft. B. M. oak piling at \$14.....	125.00
215 bbls. Buffalo cement at \$0.85.....	182.75
7½ bbls. Dykerhoff cement at \$3.00.....	22.50
Coal for engine	55.80
Coal for blacksmith	3.46
Total	\$389.50
Time work	95.57

The total actual cost to the contractor for labor and materials is accordingly $\$2,552.02 + \$389.50 + \$95.57 = \$3,177.10$. As is shown in the succeeding paragraphs the railroad company paid the contractor \$5,377.76 on the final estimate of the work done, thus giving him a profit of \$2,200.66.

In the following table is shown the final estimate of the amount of work done by the contractor and the unit rate at which he was paid by the railroad.

1,260 cu. yds. dry excavation at.....	\$0.25
372 cu. yds. wet excavation at.....	.75
27.2 cu. yds. ditching at.....	.25
796 cu. yds. back filling at.....	.25
57 cu. yds. concrete at.....	3.75
657.5 cu. yds. masonry at.....	6.15
90.4 cu. yds. old abutment torn down at.....	1.00
Total	\$5,273.62

In addition the contractor was paid for the timber left in the structure and for time labor, the unit costs being as follows:

8,932 ft. B. M. oak sheet piling at	\$14.90
8 days' labor night watchmen at.....	1.25
41 days' labor night watchmen at.....	1.50
2.8 days' labor changing braces at.....	1.50
13.25 days' labor excavating at.....	1.50
Total	\$95.57

The contractor was paid 10 per cent of this last total, or \$9.56, for use of tools, etc., making \$5,377.76 as the total amount paid

him on the final estimate. As the railroad company furnished the stone the grand total cost of the work to it was as follows:

600 cu. yds. stone at \$5.89.....	\$3,532.05
74.5 cu. yds. broken stone at \$1.177.....	87.71
Amount paid contractor.....	5,377.76
Total cost of work.....	\$8,998.52

The cost to the railroad company of masonry per cubic yard was as follows: 657.5 cu. yds. stone (laid), cost \$3,532.05, \$5.37 per cu. yd.; 657.5 cu. yds. stone cut and set, \$6.15 per cu. yd. (contract price); total, \$11.52 per cu. yd. of abutment masonry.

Plan and Elevation of Piers 2, 3 and 4

Plan and Elevation of Piers 1 and 5

Fig. 12.—Bridge Pier.

Cost of Concrete Foundations for a Railway Bridge.—Mr. J. Guy Huff is authority for the following data. The original Calf Killer River bridge on the Sparta-Bon Air extension of the Nashville, Chattanooga, St. Louis Ry. consisted of two end piers, one middle pier, and a stem wall at each end, carrying Phoenix column deck trusses of the Warren type. The distance from base of rail to bridge seat was 25 ft. 1½ in. In 1905 the old superstructure was replaced by four spans of 75 ft. deck plate girders, two new con-

crete piers being constructed and the old masonry piers built up with concrete. Figures 12 and 13 show arrangement, plans and elevation of the piers.

Briefly described, the method of construction was as follows: The end piers were built up, the end vertical posts and end braces being encased, the latter being removed when the old structure was taken down; the two new piers were finished complete, the bars of the lower chords of the old bridge being boxed around, and after the old bridge had been removed these slots were filled with concrete; on both sides of the old middle pier falsework towers sufficiently strong to support the ends of the new girders were erected, and after the old spans had been taken down and the new superstructure put in place, the pier was built up.

Fig. 13.—Bridge Piers.

The old masonry was built up of concrete to the finish for 7-ft. deck plate girders, using vertical faces and not exceeding the size of the old piers. The length of this top section on the old masonry was 14 ft. on each of the piers, and the design of the new piers was similar in size and shape to the old mid-pier with its new top section.

Mixing and Placing Concrete.—The sand and aggregate, consisting of blast furnace slag obtained from South Pittsburg, Tenn., were unloaded from cars to platforms on a level with the top of rail, placed about 100 ft. south from the south end of the bridge. A cubical form, 1-6 cu. yd. capacity, concrete mixer was used. This was operated by a gasoline engine, and was located on a platform about 50 ft. south of the south end pier. A tank near the mixer to supply water was elevated enough to get the desired head, and was kept filled by a pump run by another gasoline engine located

down by the river bank. The cement house was located between the mixer platform and slag pile.

Slag and sand were delivered to the mixer by means of wheelbarrows. The mixer was so placed that it would dump onto a platform, and the concrete could then be shoveled into a specially designed narrow-gage car. This car ran on one rail of the main track and an extra rail outside. A turnout for clearing passing trains was provided at both ends of the bridge. The track over the bridge from the mixer had a descending grade of about 1 per cent, so that with a little start the concrete car would roll alone down to the required points on the bridge. Only in returning the empty cars to the mixer was it necessary to push it by hand, and then only for a distance of never more than 400 ft.

Over the piers on the bridge in the center of the concrete car's track openings were sawed to let the concrete pass to the forms below. To get the concrete into the forms, there were used zigzag chutes with arms about 10 ft. long, which sections were removed as the concrete in the forms were increased. This chute was a convenience by its end alternating from one side to the other as the arms were removed in coming up.

Cost Data on the Foundation Work.—The foundation work was built by the railway's masonry gangs, the work being commenced about June 20, 1905, and finished complete about Dec. 1 of the same year. The girders were furnished and placed by a bridge company.

In Table XVIII the wages per day are the average rates. The men worked 10 hours each day. The concrete was mixed in a 1 : 2 : 6 proportion.

TABLE XVIII.
Unloading Materials.

	Rate per day.	Total days worked.	Total.	Per cu. yd. Con- crete.
Foreman	\$3.40	5	\$17.00	\$0.04
11 laborers	1.36 8/10	52	71.14	.15

Cofferdam Concrete (37 Cu. Yds.)

Foreman	\$3.40	8	\$27.20	\$0.06
11 laborers	1.36 3/10	79	107.68	.33
Cofferdam lumber, 3.25 M ft. at \$20.00 ..			45 00	.09
Total for cofferdam concrete				\$0.38

Concrete Mixing and Placing.

Foreman	\$3.40	30	\$102.00	\$0.22
9 laborers	1.15 6/10	282	325.99	.74
Cement, 452 bbls. at \$1.55			701.50	1.52
Slag, 427 cu. yds. at \$0.20			87.40	.19
Sand, 229 cu. yds. at \$0.30			68.00	.14
Total for mixing and placing				\$2.78

Taking Down Forms and Clearing Up.

Foreman	\$3.40	13	\$44.20	\$0.09
11 laborers	1.17	143	167.31	.36
Total for taking down forms, etc.			\$200.00	\$0.45
Engineering and supervision43
Grand total, 460 cu. yds. concrete				\$6.46

The cofferdam work was done in connection with the construction of the fourth pier, this pier being the only one coming in the bed of the river to be built entirely new. The work on this was started in water about 6 ft. deep. The 37 cu. yds. of concrete are included in the total of 460 cu. yds. in the above tabulation. By itself the cost of the cofferdam work, not including cost of cement, sand and slag, was as follows:

	Total.	Per cu. yd. Concrete.
Lumber	\$ 45.00	\$1.21
Labor, excavating	113.32	3.06
Labor, concrete	134.88	3.64
Total 37 cu. yds. concrete		\$7.91

Cost of a Cofferdam and Concrete Pier on Pile Foundation.—

The following was published in *Engineering-Contracting*, May 29, 1907:

This pier (Fig. 14) was built in water averaging 6 ft. deep. The cofferdam consisted of triple-lap sheet piling, of the Wakefield pattern, the planks being 2 ins. thick, and spiked together so as to give a cofferdam wall 6 ins. thick. The cofferdam enclosed an area 14x20 ft., giving a clearance of 1 ft. all around the base of the concrete pier, and a clearance of 2 ft. between the cofferdam and the outer edge of the nearest pile. The cofferdam sheet piles were 18 ft. long, driven 11 ft. deep into sand, and projecting 2 ft. above the surface of the water.

The concrete base resting on the foundation piles was 12x18 ft. The concrete pier resting on this base was 7x18 ft. at the bottom.

and 6x11 ft. at the top. The pier supported deck plate girders. There were 100 cu yds. of concrete in the pier and base.

The cost of this pier, which is typical of several others built at the same time, was as follows:

Setting Up and Taking Down Derrick and Platform—

4 days foreman at \$5.00.....	\$20.00
$\frac{3}{4}$ days engineman at \$3.00.....	2.25

20 days rental of plant at \$5.00	100.00

Total cost of pier\$1,252.00

Regarding the item of plant rental, it should be said that the plant consisted of a pile driver, a derrick, a hoisting engine, and sundry timbers for platforms. There was no concrete mixer. Hence an allowance of \$5 per day for use of plant is sufficient.

It will be noted that no salvage has been allowed on the lumber for forms. As a matter of fact, all this lumber was recovered, and was used again in similar work.

Referring to the cost of cofferdam work, we see that, in order to excavate the 58 cu. yds. inside the cofferdam, it was necessary to spend \$284, or nearly \$5 per cu. yd., before the actual excavation was begun. The work of excavating cost only 57 cts. per cu. yd., but this does not include the cost of erecting the derrick which was used in raising the loaded buckets of earth, as well as in subsequently placing the concrete. The sheet piles were not pulled, in this instance, but a contractor who understands the art of pile pulling would certainly not leave the piles in the ground. A hand pump served to keep the cofferdam dry enough for excavating; but in more open material a power pump is usually required.

The above costs are the actual costs, and do not include the contractor's profits. His bid on the work was as follows:

Piles delivered	12 ct. per ft.
Piles driven	\$5 each
Cofferdam	\$37 per M.
Wet excavation	\$1.00 per cu. yd.
Concrete	\$8.00 per cu. yd.

In order to ascertain whether or not these prices yielded a fair profit, it is necessary to distribute the cost of the plant transportation and rental over the various items. We have allowed \$120 for plant transportation and rental, and \$70 for setting up and taking down the plant, or \$190 in all. The working time of the plant was as follows:

	Days.	Per cent of time.	Prorated plant cost.
Cofferdam	7	39	\$ 74
Excavation	2	11	21
Foundation piles	4	22	42
Concrete	5	28	53
<hr/> Total	<hr/> 18	<hr/> 100	<hr/> \$190

As above given, the labor on the 7,900 ft. B. M. in the cofferdam cost \$126, or \$16 per M.; but this additional \$74 of prorated plant costs, adds another \$9 per M., bringing the total labor and plant to \$25 per M., to which must be added the \$20 per M. paid for the timber in the cofferdam, making a grand total of \$45 per M. This shows that the contractor's bid of \$37 per M. was much too low.

The labor on the excavation cost 57 cts. per cu. yd., to which must be added the prorated plant cost of \$21 distributed over the 58 cu. yds., or 36 cts. per cu. yd., making a total of 93 cts. per cu. yd. This shows that the bid of \$1 per cu. yd. was hardly high enough.

The labor on the 24 foundation piles cost \$80, or \$3.33 each. The prorated plant cost is \$42, or \$1.75 per pile, which, added to \$3.33, makes a total of \$5.08. This shows that the bid of \$5 per pile for driving was too low. However, there was a profit of 2 cts. per ft., or 80 cts. per pile, on the cost of piles delivered.

The concrete amounted to 100 cu. yds. Hence the prorated plant cost of \$53 is equivalent to 53 cts. per cu. yd. Hence the total cost of the concrete was:

	Per cu. yd.
Cement, sand and stone.....	\$3.20
Foreman (at \$5)	0.25
Labor (at \$2)	1.00
Engineman (at \$3)	0.15
Coal (at \$3)	0.06
Carpenters (at \$3).....	0.24
Forms (at \$22.50, used once).....	0.80
Wire nails, etc.	0.02
Prorated plant cost	0.53
<hr/> Total	<hr/> \$6.25

Since the contract price for concrete was \$8 per cu. yd., there was a good profit in this item.

It is doubtful whether many contractors analyze their costs in this manner, prorating plant costs and like, but no other method is satisfactory. Such an analysis frequently discloses the economy of radically changing the method of doing the work. For example, on abutment work, and on some piers, it is often wise not to erect a derrick at all, but to build inclined runways up which to wheel the concrete. As the pier or abutment rises in height, the runways are raised. The added cost of labor is more than offset by the saving in the cost of transporting and erecting a derrick where the yardage to be moved is small.

In like manner the excavation of a small amount of earth from the cofferdam may be more economically accomplished by shoveling it out in "lifts," than by installing a derrick for the purpose.

On the other hand, few contractors have given much study to economic methods of erecting and moving derricks, etc. A little brains put into this end of the work, may abundantly justify the use of derricks even on small jobs.

We urgently recommend the careful recording and analysis of the cost of erecting and shifting plants, as well as a similar analysis of all other costs.

The foregoing analysis should make it clear to engineers that seemingly high bids on work involving one or more small units of construction, may, in fact, prove to be too low.

Cost of a Pneumatic Caisson and Masonry Bridge Pier.*—The following data relate to the cost of labor and materials required for three railway bridge piers built by the pneumatic caisson process. The work was done for the railway company in the state of Washington, by a contractor working on a percentage basis, but the costs are the actual costs, not including the contractor's percentage.

Borings were made along the line of the bridge and the bottom was penetrated with a 2-in. pipe to a depth of 34 ft. below extreme low water. The material encountered was a very uniform bed of fine sand.

Plant.—A scow 30 ft. x 80 ft. x 4 ft. was built and was equipped with 3 boilers having an aggregate capacity of 125 hp. There were 2 air compressors; 1 air receiver; 1 duplex Knowles pump, with 12x18-in. cylinders and 60-in. discharge; 1 small pump for supplying water into the receiver; 3 air locks, 4 ft. diameter by 8 ft. high; 8 sections main air shaft, 8 ft. diameter by 8 ft. high; 2 hoppers, 3 ft. diameter by 2½ ft. high, for 18-in. supply shaft; rubber hose, various iron pipes, etc.

Pneumatic Caissons, Pier No. 2.—There were three caissons. Pier No. 2 was a pivot pier, supporting a single track draw bridge 240 ft. long. Piers Nos. 1 and 3 supported the ends of this draw span and the two 70-ft. plate girder spans approaching it.

**Engineering-Contracting*, May 8, 1907.

The caisson for this pivot pier was 30x30 ft. square and 15 ft. high. It was built of 12x12-in. surfaced timbers, sheathed both outside and inside with 3-in. surfaced plank, nailed vertically, and calked with oakum. The cutting edge was made of $\frac{3}{8}$ -in. iron, 3 ft. high, with shoulder 2 ft. wide, stiffened by brackets at intervals of 1 ft. to 2 $\frac{1}{2}$ ft. The 12x12 timbers were drift bolted together with 1-in. bolts, and the whole structure tied with 1 $\frac{1}{4}$ -in. and 2-in. rods. The corners were protected by $\frac{1}{4}$ -in. iron plates.

The cutting edge of the caisson was sunk to a depth of 55 ft. below water level or 45 ft. below ground level, requiring the excavation of 1,500 cu. yds.

When the caisson was built up 10 ft. above the cutting edge, the inside and the outside linings were spiked on and calked. The bottom sections of the supply shaft and air lock were inserted and tightly fitted. A temporarily false bottom of 3-in. plank, well calked, was made for the purpose of floating the caisson into place, after which the work of adding to its height was continued.

Meanwhile 11 guide piles were driven to guide the caisson during sinking.

The day after the caisson was in position the filling of the top part with concrete was begun, and lasted five days. Compressed air was introduced into the caisson the second day after it was in position, and on the third day three eight-hour shifts began work, the first work being the chopping out of the false bottom referred to above. By this time a cofferdam, 16 ft. high, had been constructed on top of the caisson, so as to prevent floods from interfering with the work.

It required just 29 days of 24 hrs. to sink the caisson 45 ft. after it was in place, although the actual time of sinking was 19 days, there being several delays. Then the working chamber was filled with concrete. Sections 2 ft. by 2 ft. were dug out under the shoulder of the cutting edge, and successively filled with concrete. Having thus supported the caisson, the center portion was excavated and filled with concrete. The filling of the working chamber and lower air locks with concrete took 7 days. The compressed air was then taken off, having been used for 36 days. The depth sunk was 45 ft., or 1 $\frac{1}{4}$ ft. per day.

The masonry on top of the caisson was finished 18 days after the compressed air had been turned off, so that 54 days after the caisson had been floated to place the pier was ready to receive the bridge.

The masonry on top of the caisson consisted of an annular cylinder of cut stone masonry, 50 ft. high, having a thickness of 4 $\frac{1}{2}$ ft. at the base and 3 $\frac{1}{2}$ ft. at the top. This cylinder was filled with concrete. The outside diameter of the masonry cylinder was 26 ft. at the top and 29 ft. at the base. The height of this masonry cylinder was 50 ft. The cost of the plant was as follows:

The scow was 30x80x4 ft., provided with a boiler house, and its cost was:

30,600 ft. B. M., timber in scow at \$15.....	\$459.00
1,400 lbs. boat spikes at 4c.....	56.00
800 lbs. bolts, screws, etc., at 2c.....	16.00
2,000 lbs. oakum at 4c.....	80.00
5 bbls. tar at \$5.....	25.00
Miscellaneous materials	20.00

Total materials in scow.....\$664.00

22,000 ft. B. M., in boiler house at \$15.....	\$330.00
1,300 lbs. nails, etc.....	40.00
800 lbs. tarred paper at 2½c.....	20.00
1,000 brick	8.00
1 bbl. lime	1.50
Miscellaneous materials	10.00

Total materials in boiler house.....\$409.50

Labor building scow and boiler house:

15 days, foreman, at \$4.....	\$ 60.00
240 days, carpenters, at \$3.05.....	720.00
60 days, laborers, at \$2.....	100.00

Total labor

\$880.00

This labor cost is equivalent to \$16 per 1,000 ft., B. M., of timber in the scow and boiler house. The cost of setting up the boilers, compressors, etc., was as follows:

12 days, foreman, at \$4.....	\$ 48.00
24 days, carpenter, at \$3.....	72.00
4 days, machinist, at \$5.....	20.00
3 days, blacksmith, at \$3.50.....	10.50
60 days, steam fitter, at \$3.50.....	175.00
24 days, engineman, at \$3.50.....	84.00
270 days, laborer, at \$2.....	540.00

387 days. Total

\$949.50

This cost is also excessive and indicates very poor management.

The freight on this plant was \$150. Summarizing, we have:

Scow and boiler house	\$1,950
Setting up boilers, etc	950
Freight	150

Total

\$3,050

Charging this \$3,050 to the three piers according to their size, we may assign 50 per cent, or \$1,525, to Pier No. 2, and \$762 to each of the other two piers.

The three boilers, two air compressors, pumps, etc., were worth about \$4,000, and a very liberal allowance for their use on this job would be \$2,000, charging 50 per cent, or \$1,000, to Pier No. 2, and \$500 to each of the other two piers. This \$1,000 added to the \$1,525, makes \$2,525 charged for plant. The cost of erecting a platform and derrick at Pier No. 2 was \$100. About 250 ft. of 4-in. pipe and 70 ft. of 1½-in. pipe and fittings, costing \$120, were left in the caisson and not recovered.

About 36,000 lbs. of iron were required for the air locks, shafts, etc., of the three piers. About half of it, or 18,000 lbs., was left

in the piers, for which a charge of 5c per lb. was made, or \$900, or \$300 per pier.

The cost of materials in the caisson (30x30x15 ft.) was as follows:

71,000 ft. B. M. in caisson at \$20.....	\$1,420.00
4,400 ft. B. M. in false floor at \$20.....	88.00
3,400 ft. B. M. in inside curbing at \$20..	68.00
9,000 ft. B. M. in cofferdam.....	180.00
15,000 lbs. cutting edge at 4½c.....	675.00
1,400 lbs. corner plates at 4c.....	56.00
5,200 lbs. rods at 2½c.....	130.00
4,000 lbs. drift bolts at 2½c.....	100.00
3,000 lbs. boat spikes at 2c.....	60.00
800 lbs. cast washers at 2c.....	16.00
1,000 lbs. lag screws, etc., at 4c.....	40.00
20 bales (2,000 lbs.) of oakum at \$4....	80.00
100 lbs. rubber packing at 70c.....	70.00

Total materials\$2,983.00

There were 78,800 ft. B. M. in the caisson, exclusive of the 9,000 ft. B. M. in the cofferdam. The cost of framing and erecting the caisson was as follows:

45 days, foreman, at \$4.....	\$ 180.00
320 days, carpenters, at \$3.....	960.00
90 days, laborers, at \$2.....	180.00
14 days, blacksmiths, at \$3.50.....	49.00
10 days, engineman, at \$3.50.....	35.00
7 days, machinist, at \$5.....	35.00

486 days, total, at \$2.96.....\$1,439.00

This is equivalent to \$18.25 per 1,000 ft. B. M., which is a very high cost for this kind of work.

The cost of building the cofferdam on top of the caisson was as follows:

6 days, foreman, at\$4.00	\$ 24.00
60 days, carpenters, at.....	3.00 180.00
10 days, laborers, at	2.00 20.00
3 days, blacksmith, at.....	3.50 10.50
79 days, total	\$2.97 \$234.50

Since there were 9,000 ft. B. M. in the cofferdam, the labor cost \$26 per 1,000 ft. B. M.

The cost of sinking the caisson, which included tamping the concrete in the working chamber of the caisson also, was as follows:

34 days, foreman machinist, at..\$5.00	\$ 170.00
16 days, general foreman, at.....	6.00 96.00
80 days, sub foreman, at	5.00 400.00
64 days, top lock tender, at....	2.25 144.00
720 days, pressure men, at.....	3.50 2,520.00
72 days, enginemen, at	3.50 252.00
72 days, firemen, at	2.75 198.00
32 days, coal passers, at	2.50 80.00
40 days, wipers, at	2.00 80.00
50 days, steam fitters, at	3.00 150.00
4 days, blacksmith, at	3.50 14.00
58 days, carpenters, at	3.00 174.00
360 days, laborers, at.....	2.00 720.00
32 days, signal man, at	2.00 64.00
32 days, call boy, at	1.00 32.00

1,706 days total\$2.99 \$5,094.20

As above stated, it required 36 days to sink the caisson and fill the working chamber with concrete, hence by dividing each of the above items by 36 we get the number of each kind of men per day.

In addition to the materials and labor above enumerated, there were the supplies, which cost as follows:

220 tons coal at \$3.....	\$660.00
220 gals. gasoline and kerosene, at 10c...	20.00
40 gals. valve oil at 50c.....	20.00
20 gals. engine oil at 35c.....	7.00
70 lbs. waste at 5c.....	3.50
45 prs. rubber boots at \$3.....	135.00
Total	\$845.50

The guide piles around the caisson were driven with a scow driver, and cost as follows:

600 lin. ft. piles at 10c.....	\$ 60.00
Labor driving	52.00
Coal for driver, etc.	20.00
Total	\$132.00

There were 400 cu. yds. of concrete placed in the working chamber of the caisson and 400 cu. yds. inside the stone masonry on top of the caisson. The cost of this concrete was as follows:

	Per cu. yd.
1 cu. yd. stone at \$1.....	\$1.00
0.45 cu. yd. sand at 80c.....	.36
0.7 bbl. cement at \$2.....	1.40
Mixing and placing	1.15
Erecting derricks, platforms, etc.....	.34
Total	\$4.25

The \$1.15 for "mixing and placing" covers the wages of the men (\$2 a day) engaged in hand mixing and handling the concrete, the derrick engineman, the foreman, the lock tenders, and the coal; but it does not include the placing and tamping of the concrete in the working chamber of the caisson, for that item is included in the cost of sinking the caisson.

There were 400 cu. yds. of concrete in the caisson and 400 cu. yds. of concrete on the top of it, but of this last 400 cu. yds. only 60 per cent, or 240 cu. yds., was below the ground level. Hence we have $400 + 240 = 640$ cu. yds. of concrete below the ground level. This 640 cu. yds., at \$4.25, cost \$2,720, which is equivalent to \$63 per lin. ft., or \$1.93 per cu. yd. of pier below the ground level.

We may now summarize the cost as follows:

	Total.	Per lin. ft. (45 ft.)	Per cu. yd. (1,500 cu. yds.)
Plant, proportionate cost.....	\$2,525	\$ 56	\$1.68
Setting up platform and derrick...	100	2	0.07
Pipe left in caisson	130	3	0.09
6,000 lbs. iron left in caisson.....	300	7	0.20
78,800 ft. B. M. caisson, \$20.....	1,576	35	1.06
9,000 ft. B. M. cofferdam, \$20....	180	4	0.12
16,000 lbs. cutting edge, 4 1/4 c....	675	15	0.45
9,200 lbs. rods, drifts, etc., 2 1/4 c....	230	5	0.16
6,200 lbs. boat spikes, etc.....	172	4	0.11
2,200 lbs. oakum, 4c.....	80	2	0.05
100 lbs. rubber packing, 70c.....	70	2	0.05
486 days bldg. caisson, \$2.96.....	1,439	32	0.96
79 days building cofferdam, \$2.97...	235	5	0.16
1,076 days sinking, \$2.99.....	5,084	112	3.39
220 tons coal, \$3.00.....	660	15	0.44
Other supplies	185	4	0.12
600 lin. ft. piles delivered, 10c....	60	1	0.04
600 lin. ft. piles driven, 12c.....	72	2	0.05
Supt. and office exp.....	700	16	0.47
Totals	\$14,483	\$322	\$9.66

The cost of cutting and handling the sandstone for the masonry was as follows.

	Per cu. yd.
2.8 days, stone cutter, at \$6.....	\$1.68
3.2 days, laborer, at \$2.....	0.64
0.04 day, blacksmith, at \$3.50.....	0.14
0.04 day, blacksmith helper, at \$2.50.....	0.10
0.06 day, horse, at \$1.50.....	0.09
Total	\$2.65

The total cost of this stone masonry was as follows:

	Per cu. yd.
1 cu. yd. stone at \$6.50.....	\$ 6.50
Cutting stone	2.65
Setting stone	0.95
0.08 cu. yd. sand at 80c.....	0.05
0.2 bbl. cement at \$2.....	0.40
Total	\$10.55

There were 600 cu. yds. of this stone masonry, hence its cost was \$6,330. About 60 per cent of it, or \$3,798, was below the ground level.

Summarizing the cost of the pier below the ground level, we have:

	Total.	Per lin.ft.	Per cu. yd.
Brought forward	\$14,483	\$322	\$ 9.66
Concrete at \$4.25.....	2,806	62	1.93
Masonry at \$10.55	3,798	84	2.53
Total	\$21,086	\$468	\$14.12

The cost of the 20 lin ft. of pier above the ground level was:

160 cu. yds. concrete at \$4.25.....	\$ 680
240 cu. yds. masonry at \$10.55.....	2,532

Total, 20 lin. ft., at \$160.....\$3,212

The total cost of the pier was \$24,298.

The reader will note that the tabulated cost of this caisson is given in such shape that the cost of similar work can be easily estimated by allowing for differences in prevailing prices and wages. If timber costs \$20 per M, instead of \$20, then, by adding 50 per cent to the items involving timber, the increased cost per cubic yard of caisson is readily estimated. Since the timber in the caisson cost \$1.05 per cu. yd. of caisson, when timber was \$20 per M, it is evident that, with timber at \$30 per M, this item of \$1.05 will be increased 50 per cent, making it \$1.58 per cu. yd. of caisson. In like manner other items may be raised or lowered, almost by inspection, and a total secured which will be a very accurate estimate. The above costs do not include "engineering," which, in this case, was about 6 per cent of the total.

In a succeeding issue will be given the cost of the two caissons (piers Nos. 1 and 2) mentioned in the first part of this article; and in that issue we shall compare the costs of caissons in piers Nos. 1, 2 and 3, showing that the cubic yard is the proper unit to use in recording and comparing the cost of caisson work, and not the lineal foot. The lineal foot, it is true, has long been regarded as a convenient unit of caisson costs, but it is wholly unreliable for comparative purposes, and should be abandoned.

Cost of Two Pneumatic Caissons and Masonry Bridge Piers.*—In our last issue we gave a general description of a large pivot pier caisson and plant used in sinking it to a depth of 45 ft. In this issue we shall give the itemised cost of two smaller caissons of the same type, sunk with the same plant described in our last issue, and under the same conditions. Each of these caissons was 16 x 24 ft. in cross-section, and 15 ft. high; and on top of each was built the masonry pier as fast as the caisson was sunk. These two "rest piers" will be designated as piers No. 1 and No. 2. The masonry was built to a height of 51 ft. above the top of the caisson, or 13 ft. above water level. The cutting edge of the caisson of pier No. 1 reached 47 ft. below ground level, or 53 ft. below water level. The cutting edge of pier No. 2 reached the same distance below water level, but only 38 ft. below ground level.

The masonry of each pier had a cross-section of 11 x 22 ft. at the base, and 7 x 24 ft. under the coping. The masonry was cut stone (sandstone), excepting a core of concrete, 4 x 10 ft., 29 ft. high above the top of the caisson. The working chamber of the caisson was filled with concrete after it had been sunk to the proper depth.

Cost of Pier No. 1.—Eighteen days after the caisson was launched the sinking was begun. Eleven days after the sinking began, the sinking was completed, but the compressed air was not taken off until 17 days after the sinking began. The masonry pier was completed 54 days after the sinking began.

Since the cross-section of the caisson was 544 sq. ft. and it was sunk to a depth of 47 ft., the excavation amounted to 247 cu. yds.

The proportionate charge for the use of the plant for this pier was \$1,262.

**Engineering-Contracting*, May 15, 1907.

There were 6,000 lbs. of iron (air shafts, etc.) left in the pier, for which a charge of 5 cts. per lb., or \$300, was made.

There were 160 ft. of 4-in. pipe, and 40 ft. of 1½-in pipe and fittings, worth \$100, left in the pier.

The cost of materials in the caisson was as follows:

		Per Lin. Ft. (47 ft.)	Per Cu. Yd. (347 cu. yds.)
Plant, proportionate cost.....	\$1,262	\$ 27	\$ 1.32
Setting up derrick and platform	90	2	0.10
Pipe left in caisson.....	100	2	0.10
6,000 lbs. iron left in caisson..	300	6	0.32
51,000 ft. B. M. caisson, \$20...	1,020	22	1.08
13,000 lbs. cutting edge, 4½ cts.	585	13	0.62
8,000 lbs. rods and drifts, 2½.	200	4	0.21
5,000 lbs. boat spikes, etc.....	136	3	0.14
1,500 lbs. oakum, 4 cts.....	60	1	0.06
100 lbs. rubber packing, 70 cts.	70	2	0.07
321 days building caisson, \$2.94	945	21	1.00
943 days sinking caisson, \$3.10.	2,929	62	3.09
100 tons coal, \$3.00.....	300	6	0.32
Other supplies	109	2	0.11
Supt. and office expense.....	440	9	0.47
Total	\$8,646	\$182	\$ 9.02
280 cu. yds. concrete, \$4.25...	1,190	25	1.25
Total	\$9,736	\$207	\$10.27
46,000 ft. B. M. in caisson, at \$20.....	\$ 920		
2,000 ft. B. M. in false floor, at \$20.....	40		
13,000 lbs. cutting edge, at 4½ cts.....	585		
1,300 lbs. corner plates, at 4 cts.....	62		
5,000 lbs. rods, at 2½ cts.....	125		
3,000 lbs. drift bolts, at 2½ cts.....	75		
2,400 lbs. boat spikes, at 2 cts.....	48		
800 lbs. cast washers, at 2 cts.....	16		
500 lbs. lag screws, etc., at 4 cts.....	20		
15 bales (1,500 lbs.) oakum, at \$4.....	60		
100 lbs. rubber packing, at 70 cts.....	70		

Total materials.....\$2,071

There were 51,000 ft. B. M. in the caisson.

The cost of framing and erecting the caisson was:

30 days, foreman, at.....	\$4.00	\$120.00
220 days, carpenters, at.....	3.00	660.00
60 days, laborers, at.....	2.00	120.00
7 days, blacksmith, at.....	3.50	24.50
4 days, machinists, at.....	5.00	20.00
321 days, total, at.....	\$2.94	\$944.50

This is equivalent to \$18.50 per 1,000 ft. B. M., which is a very high cost.

The cost of sinking the caisson, which includes tamping the concrete in the caisson also, was as follows:

18 days, foreman machinist, at..	\$5.00	\$ 90
24 days, general foreman, at....	6.00	144
48 days, sub-foremen, at.....	5.00	240
36 days, top lock tender, at.....	2.25	81
380 days, pressure men, at.....	3.50	1,330
44 days, enginemen, at ..	3.50	154
44 days, firemen, at.....	2.75	121
38 days, coal passers, at.....	2.50	95
24 days, steamfitters, at	3.00	72
2 days, blacksmith, at.....	3.50	7
30 days, carpenter, at.....	3.00	90
250 days, laborers, at.....	2.00	500
5 days, call boy, at.....	1.00	5
943 days, total, at.....	\$3.10	\$2,929

The coal supplies used in sinking the caisson were as follows:

100 tons coal, at \$3.....	\$300.00
70 gal. gasoline and kerosene, at 10 cts.	7.00
180 lbs. candles, at 12 cts.....	19.20
3,000 ft. B. M. in inside curb, at \$20.....	60.00
20 lbs. valve oil, at 50 cts.....	10.00
10 lbs. engine oil, at 35 cts.....	3.50
35 lbs. waste, at 5 cts.....	1.75
20 pairs rubber boots, at \$3.....	60.00
100 lbs. red lead, at 8 cts.....	8.00
Total	\$409.45

There were 200 cu. yds. of concrete placed in the working chamber of the caisson and 80 cu. yds. in the pier, the cost being \$4.25 per cu. yd., as given in our last issue.

We may now summarize the total cost as follows:

In addition to the above there were 480 cu. yds. of stone masonry, the actual cost of which was \$10.55 per cu. yd., or \$5,064. About 330 cu. yds. of this masonry was below the ground level, which is equivalent to \$3,481 of stone masonry below the ground level. Dividing this by 47, we have \$74 per lin. ft.

Summarizing, we have the following cost of pier No. 1 below the ground level:

	Total	Per lin. ft.	Per cu. yd.
Caisson, etc.....	\$ 3,546	\$182	\$ 9.02
280 cu. yds. concrete at \$4.25....	1,190	25	1.25
330 cu. yds. masonry, at \$10.55....	3,481	74	3.66
Total	\$13,217	\$281	\$13.93
150 cu. yds. masonry above ground level, at \$10.55.....	1,583		
Grand total	\$14,800		

Cost of Pier No. 3.—The design of this pier was the same as of Pier No. 1. It differed somewhat in cost, however, since it was sunk to a depth of only 28 ft. below ground level, due to the fact that the water was deeper at the site of this pier than at the site of pier No. 1.

Fifteen days after the caisson was launched, the sinking began. It took 15 days to sink the caisson, and 4 days more to fill the

working chamber with concrete, making 19 days of work under air pressure. The masonry pier was completed 37 days after the sinking was begun. The cost of materials in the caisson was the same as for pier No. 1.

The cost of framing and erecting the caisson was:

29 days, foreman.....	\$4.00	\$116.00
218 days, carpenters.....	3.00	654.00
58 days, laborers.....	2.00	116.00
9 days, blacksmith	3.50	\$1.50
4 days, machinist.....	5.00	20.00
<hr/>		
318 days, total.....	\$2.95	\$937.50

This is equivalent to \$19 per M.

The cost of sinking the caisson, which included tamping the concrete in the caisson also, was as follows:

18 days, foreman machinist....	\$5.00	\$ 90.00
30 days, general foreman.....	6.00	180.00
38 days, sub-foreman	6.00	190.00
33 days, top lock tender.....	2.00	66.00
340 days, pressure men.....	3.50	1,190.00
50 days, enginemen	3.50	175.00
46 days, firemen	2.75	126.50
20 days, coal passers.....	2.50	50.00
28 days, steamfitters	3.00	84.00
2 days, blacksmith	3.50	7.00
16 days, carpenter ..	3.00	48.00
220 days, laborers	2.00	440.00
<hr/>		
851 days, total	\$3.11	\$2,646.50

The coal and supplies used in sinking the caisson were as follows:

120 tons coal, \$3.....	\$360.00
70 gals. gasoline, etc., 10 cts.....	7.00
175 lbs. candles, 12 cts.....	21.00
20 gals. valve oil, 50 cts.....	10.00
12 gals. engine oil, 35 cts.....	4.20
35 lbs. waste, 5 cts.....	1.75
24 pairs rubber boots, \$3.....	72.00
100 lbs. red lead, 8 cts.....	8.00
<hr/>	
Total	\$483.95

The guide piles cost as follows:

620 lin. ft., delivered, 10 cts.....	\$ 62.00
620 lin. ft. driven, 10 cts.....	62.00
<hr/>	
Total	\$124.00

Summarizing we have:

	Total.	Per Lin. Ft. (33 ft.)	Per Cu. Yd. (766 cu. yds.)
Plant	\$1,262	\$ 33	\$ 1.45
Setting up derrick and platform..	120	3	0.16
Pipe left in caisson.....	150	4	0.30
6,000 lbs. iron left in caisson...	300	8	0.39
50,000 ft. B. M. left in caisson, \$30	1,000	26	1.31
13,000 lbs. cutting edge, 4½ cts..	585	16	0.76
8,000 lbs. rods and drifts, 2½ cts.	200	5	0.26
5,000 lbs. boat spikes, etc.....	136	4	0.18
1,500 lbs. oakum, 4 cts.....	60	2	0.08
100 lbs. rubber packing, 70 cts..	70	2	0.09
318 days building caisson, \$295..	938	25	1.22
851 days sinking caisson, \$3.11..	2,646	71	3.45
120 tons coal, \$3.00.....	360	9	0.47
Other supplies.....	124	3	0.16
Supt. and office exp.....	440	11	0.57
Total	\$8,391	\$221	\$10.95
280 cu. yds. concrete, \$4.26.....	1,190	31	1.55
Total	\$9,581	\$252	\$12.50

In addition to the above there were 480 cu. yds. of stone masonry, the cost of which was \$10.55 per cu. yd., or \$5,064. Adding this to the \$9,581, we have a total cost of \$14,645 for pier No. 2.

Let us compare the costs of piers Nos. 1, 2 and 3. Referring to our issue of May 8, we find the cost of pivot pier No. 2. In making the comparison we shall exclude the cost of the masonry and concrete.

	No. 1.	No. 2.	No. 3.
Cost per cu. yd., displaced.....	\$9.02	\$9.66	\$10.95
Cost per lin. ft. below ground level	1.82	2.22	2.21

It is perfectly evident, from this comparison, that the lineal foot of distance sunk below the ground level is not a rational unit to be used in comparing the cost of pneumatic caisson work. On the other hand, the cubic yard of displaced earth is a much more rational unit. Obviously the cost of the masonry should be estimated separately, excepting possibly the concrete used in filling the working chamber of the caisson.

The foregoing data relate to work carried on at moderate depths below the water level.

Cost of a Caisson in Arizona.—Mr. S. M. Rowe gives the following data relative to a caisson for the Red Rock cantilever bridge, built in 1889, across the Colorado River in Arizona for the Atlantic and Pacific R. R. Co.

The caisson was 30 x 60 ft. in cross-section and 17 ft. high, surmounted by a timber crib 47 ft. high, the height from the cutting edge to the top of the crib being 64 ft. The ordinary low water level was at the top of the crib, and the depth of water (at low water) was only 4 ft. The material penetrated was mostly sand, gravel and boulders. So compact was the material at a depth of 61 ft. that it was practically impossible to reach bed rock.

The caisson and crib were of Oregon pine, and the following was the bill of material:

	Ft. B. M.
Working chamber (incl. 3 ins. casing inside).....	82,560
Roof, 8 ft. thick.....	155,904
Crib (incl. 3 ins. casing outside).....	240,855
Total timber (neat).....	479,319
Iron bolts and spikes	58,000 lbs.
Concrete in crib (47.7 cu. yds. per lin. ft.).	2,290 cu. yds.
Concrete in working chamber.....	580 cu. yds.
Total concrete.....	2,870 cu. yds.

It is stated that the timber weighed 35 lbs. per cu. ft. when well dried, and that it absorbed 28 lbs. of water per cu. ft.

There were 1,480 cu. yds. of solid timber and 2,870 cu. yds. of concrete, making a total of 4,350 cu. yds. as the volume of the caisson and crib, the timber being 34% of the total volume.

The total cost was \$128,263, or nearly \$30 per cu. yd., of which \$16.50 is labor, which is an exceedingly high cost. The following is the itemized cost of the caisson:

Timber (480 M).....	\$ 7,885.02
Iron and steel (58,000 lbs.).....	2,180.13
Piling	315.24
Tools and materials.....	8,415.65
Fuel and water.....	7,158.30
Cement for 2,870 cu. yds. concrete.....	9,568.00
Freight	13,363.20
Local and train service.....	2,790.98
Labor	71,754.02
Engineering	5,052.67
Total	\$128,263.19

This did not include the building of a trestle across the river to the site of the caisson, which cost \$6,238, nor the tracks to the quarry, which cost \$7,313.

The following gives the labor cost for the different periods:

	Pay Roll.	Depth Sunk.	Labor Cost Per Lin. Ft.
November, 10 days.....	\$ 2,612	9.9 ft.	\$263
December, 31 days.....	10,027	23.4 ft.	429
January, 21 days.....	10,710	26.8 ft.	400

The last foot or two sunk in January cost \$2,500 per ft. for labor. In February, 11 days were spent, at a cost of \$3,760 for total labor, filling the working chamber with 580 cu. yds. of concrete.

The air plant consisted of 3 compressors (two of which were double cylinders 16 x 24 ins., and one 12 x 18 ins. Two were used while excavating and one held in reserve. These were driven by two 75-hp. boilers and by one of 50 hp. The air plant was on a boat 24 x 60 ft. built for the purpose.

The stone for the concrete was a broken volcanic rock, with which the "mesas" were strewn, which was raked into windrows and hauled by wagons to a pile where it was loaded into a car.

Cost of a Caisson in Tennessee.—Mr. Hunter McDonald gives the following data relative to a caisson for a pivot pier of a railway swing bridge built in 1893 across the Tennessee River for the Nashville, Chattanooga & St. Louis Ry., by contract.

The caisson was 36 ft. square and 16 ft. high, surmounted by a crib 28 ft. high, making a total height of 44 ft. The cutting edge was sunk through gravel and sand to a depth of 44 ft. below low water. The caisson and crib were filled with 1 : 2 : 5 natural cement concrete. The contract price of the pivot pier was as follows:

119,792 ft. B. M. timber in caisson, at \$38.....	\$ 4,552.71
95,727 ft. B. M. timber in crib, at \$28.....	2,680.37
54,976 lbs. iron, at 4 cts.....	2,199.00
96 lin. ft. shafting left in place, at \$7.....	672.00
44 lin. ft. sinking below water level, at \$344.81	15,171.42
313.4 cu. yds. material removed through lock at \$35.....	10,969.00
1,085.9 cu. yds. concrete in crib and pockets, at \$6.....	6,515.40
233.5 cu. yds. concrete in air chamber, at \$12	2,802.00
Total cost of caisson.....	\$45,562.00

Since the displacement of this 44 ft. caisson was 2,112 cu. yds., the cost was \$21.57 per cu. yd., or \$1,035 per lin. ft. of vertical height.

The cost of the stone masonry was:

415.62 cu. yds. face stone, at \$12.....	\$ 4,987.44
725.19 cu. yds. backing, at \$7.....	5,076.33
24.52 cu. yds. coping, at \$16.....	392.32
Total masonry.....	\$10,456.09

The masonry was 48 ft. high, above the top of the crib.

A caisson for a rest pier was 16½ x 40½ ft. in cross-section, and displaced 1,107 cu. yds., and cost \$19 per cu. yd., or \$476 per lin. ft. of vertical height. It contained 115,000 ft. B. M. in caisson and crib and 672 cu. yds. of concrete.

Cost of Four Caissons.—Mr. B. L. Crosby gives the following data relative to 4 caissons built in 1892 for the St. Louis, Keokuk & Northwestern R. R. for a double-track bridge across the Missouri River. The work was done by company forces. Each caisson was 30 x 70 ft. in cross-section and 16 ft. high, surmounted by a crib. The cribs were 24, 45, 58 and 64 ft. high for piers Nos. 1, 2, 3 and 4, respectively. The caissons and cribs were filled with 1 : 2 : 4 natural cement concrete.

The air plant consisted of two No. 4 Clayton duplex compressors, having steam and air cylinders, each 14 ins. with 15-in. stroke; and a Worthington duplex pump, 18½ x 10½ x 10 ins. This plant was set on a small steam boat. There was a duplicate plant mounted on a platform on piles. There were several hoisting engines, a pile-driver boat, provided with a derrick for handling the timbers, and an arc light plant for night work. The concrete was mixed

in a Cockburn Barrow Co. mixer on a barge provided with a derrick for handling concrete blocks. There were several other barges for handling timber, cement and stone, and a small steamboat for towing barges.

The caissons were built on launching ways constructed of piles capped with 12 x 12-in. timbers parallel with the river bank. The way timbers were 12 x 12-in. having a slope of 3 ins. to the foot toward the river, and were extended far enough into the river to allow the caisson to float before being clear of the timbers. The piles under water were cut off with a circular saw and caps were placed by a diver; the drift-bolts were driven by a ramrod working through a gas pipe over the drift-bolt.

Several sandbars at the sites of the piers were washed away by the paddle wheels of the steamboat, a hole 7 to 10 ft. deep being dug out in this manner. Barges were placed on each side of a caisson, and heavy timbers bolted the caisson, extending out over the barges. By pumping air into the caisson it was raised till it drew only 5 ft. of water, and blocking was placed under the timbers projecting over the barges. Then it was towed to place.

The following were the depths below "standard low water" to which the different caissons were sunk: No. 1, 68 ft.; No. 2, 89 ft.; No. 3, 101 ft.; No. 4, 83 ft.

Some blasting of the rock site of caisson No. 1 was done. Rackarock was used, because its fumes do not give the men headaches as do the fumes of dynamite in a caisson.

The total combined height of the four caissons and cribs was 255 ft., and, since their cross-section was 30 x 70 ft., this is equivalent to combined displacement of nearly 20,000 cu. yds., of which 25% was the yellow pine timber, there being 1,609,000 ft. B. M. There were 13,285 cu. yds. of 1:2:4 concrete placed in the caissons and cribs, requiring 20,800 bbls. of cement, of which 80% was natural and 20% Portland. The cost of the concrete was \$5.36 per cu. yd., including all material and labor. The cost of framing the timber and building it into the caissons was \$22 per 1,000 ft. B. M., including the cost of the launching ways, handling and towing, and all labor and materials, but not including the cost of the timber in the caissons and cribs. It is likely that in 1892 this yellow pine cost about \$18 per M. In which case the total cost was \$40 per M in place. Since 1,000 ft. B. M. = 3.08 cu. yd., each cubic yard of timber would cost \$12. If each cubic yard displaced by the caisson and cribs was 25% timber (at \$12 per cu. yd.) and 75% concrete (at \$5.36 per cu. yd.), then the average cost was \$7.20 per cu. yd., to which must be added the cost of sinking the caissons, which was \$248 per cu. yd., making a total of \$9.68 per cu. yd. displaced. As a matter of fact the total cost actually was \$9.23 per cu. yd., from which it would appear either that our assumed price of \$18 per M for the timber is a little too high, or that the percentage of timber was not quite 25%.

The material was excavated and discharged from the working chambers with a Morrison sand pump, which is a modification of the Eads sand pump.

For comparative purposes it is well to record here that a long timber trestle, built at the same time by company forces, cost \$7.42 per M for labor, including unloading, framing and erecting.

Wages are not given, except for "pressure men," who received \$3.50 a day, and worked an hour at a time for 2 or 3 hrs. a day when at the greatest depth. It is probable that common laborers received \$1.25 to \$1.50 and carpenters \$2.50 per day of 10 hrs., at that time and place.

Materials for a Caisson.—In building a single-track bridge for the Illinois Central R. R. across the Ohio River near Cairo, 10 piers were sunk 75 ft. below low water. The frictional resistance was found to be 600 to 700 lbs. per sq. ft. of exposed surface. The largest caisson and crib is 30 ft. wide, 70 ft. long and 50 ft. high. The total height of the pier is 177 ft. (50 ft. of caisson and crib filled with concrete, and 127 ft. of masonry on top). It contains the following materials:

\$21,000 ft. B. M. lumber.

137,000 lbs. iron.

2,865 cu. yds. concrete in caisson and crib.

3,800 cu. yds. masonry.

The pier measures 14 x 43 ft. on top.

The weight of the 137,000 lbs. of iron was distributed as follows:

	Lbs.
Cutting edge.....	26,583
Corner plates.....	8,108
Air locks (1 pr. doors left in).....	7,287
Sections of shaft.....	14,813
Rods.....	30,570
Washers.....	7,111
Drift bolts.....	21,606
Boat spikes.....	15,402
Lag screws.....	285
Bolts.....	331
Pipe (334 ft. of 4 in.).....	3,495
Pipe (83 ft. of 5 in.).....	1,234
Total	136,785

Cost of Erecting Three Steel Viaducts and a New Formula for Computing the Weight of Viaducts.*—In *Engineering-Contracting* of April 3, 10 and 17 and May 8, we gave the costs of erecting a number of steel bridges of different spans and types. In this issue we shall give the cost of erecting several steel viaducts, and shall briefly discuss methods of estimating the cost of steel viaducts.

The modern steel viaduct is a structure consisting of deck plate girder spans supported by steel bents resting on concrete pedestals. Each steel bent has two legs, having a batter of 2 ins. to the foot. Bents on high viaducts are spaced 30 ft. and 60 ft. apart alternately, so that the plate girder spans are alternately 30 ft. and

**Engineering-Contracting*, June 19, 1907.

60 ft. long. Every pair of bents 30 ft. apart is braced by horizontal and diagonal members, thus forming a "tower." Ordinarily, therefore, the number of towers in a viaduct is just half the number of bents; and the number of plate girder spans is just one more than the number of bents.

Estimating Weight of Viaducts.—There are excellent rules or formulas for estimating the approximate weight of plate girders and truss bridges of different spans, but the existing formulas for estimating the weight of viaducts are very unsatisfactory. The editors of this journal have deduced a new formula for estimating the weight of steel in viaducts of the type just described, but, before presenting the deduction, we shall quote the empirical formulas proposed by Mr. C. P. Howard, M. Am. Soc. C. E. They are as follows:

$W = 24 A$, for height of 20 ft.

$W = 26 A$, for height of 30 ft.

$W = 17 A$, for height of 50 ft.

W = total weight of viaduct in lbs.

A = profile area of viaduct in square feet.

The above formulas are for Cooper's E 40 loading. Add 20% for Cooper's E 50 loading.

This method of estimating the weight of viaducts by profile areas alone is a very common one, but is wholly irrational, as is seen by the fact that a different factor is necessary for different heights. The profile area, it should be explained, is the area on the profile between the base of the rail and the ground surface, or between the lower chord of the plate girders and the line joining the tops of the masonry pedestals on which the towers rest. It is in the former sense (which is most common) that we use the term profile area here, although the latter sense is to be preferred and should be generally adopted. Obviously the weight of the bents, or towers, bears some relation to this area, but it is equally obvious that the weight of the plate girders bears no relation whatever to the profile area.

For a live load of two 115-ton engines and a train weighing 3,000 lbs. per sq. ft., the average weight of plate girder spans (30 ft. and 60 ft. alternating) is about 600 lbs. per lin. ft. For the same loading, the weight of steel in each bent is about 540 lbs. per lin. ft. of height of bent, for viaducts of any considerable height. Having these data in mind, we are able to deduce a very simple and rational formula for estimating the weight of steel in high viaducts.

Let A = profile area in sq. ft.

L = length of viaduct in ft.

W = weight of viaduct in lbs.

Then:

$$\text{Average height of bents} = \frac{A}{L}$$

$$\text{Number of bents} = \frac{L}{45}$$

This last equation is slightly in error, giving one bent too few when the average length of girders is 45 ft. ($\frac{1}{2}$ of 30 + 60), but it is close enough for practical purposes. Therefore:

$$\text{Total height of all bents} = \frac{A}{L} \times \frac{L}{45} = \frac{A}{45}$$

But the weight of bents per lin. ft. of height is 540 lbs.; hence:

$$\text{Total weight of bents} = 540 \times \frac{A}{45} = 12 A.$$

The total weight of girder spans = 600 L. Therefore:

$$W = 12 A + 600 L.$$

This is a formula which the editors have used in estimating the weight of many viaducts of different heights, and, except for very low viaducts (20 or 25 ft.), or for viaducts of antiquated design, it gives very close results. Low viaducts are really trestles, with bents spaced at equal distances, and not built with bents spaced and braced so as to form towers.

We shall now pass to a consideration of the cost of erecting two viaducts, and at the close of this article will discuss the design of masonry substructures, indicating wherein we believe present practice to be extravagantly wasteful of material.

Cost of Erecting a 500-ft. Viaduct.—This viaduct weighed 340 tons and was erected by contract. The profile area was 31,500 sq. ft., and the average height was 63 ft. The following costs were the actual costs to the contractor.

The average force was:

	Per day.
1 foreman at \$5.00.....	\$ 5.00
1 foreman carpenter, at \$4.00..	4.00
1 foreman, at \$3.50.....	3.50
7 riveters, etc., at \$3.25.....	22.75
10 bridgemen, at \$3.00.....	30.00
8 carpenters, at \$2.75.....	22.00
3 laborers, at \$2.50.....	7.50
1 stationary engineer, at \$3.25.....	3.25
1 water boy, at \$1.50.....	1.50
<hr/> 33 Total gang.....	<hr/> \$99.50

It will be noted that foremen's wages constituted 12% of the total.

Time allowed traveling—

1 day at \$5.00	\$ 5.00
1 day at 4.00	4.00
1 day at 3.50	3.50
8 days at 3.25	26.00
10 days at 3.00	30.00
8 days at 2.75	22.00

Summary—

Time travelling	\$ 98.00
Loading derricks and tools	75.00
Framing traveler, etc.	66.00
Erecting traveler	65.37

Total general expense.....\$ 304.37

Erecting towers.....	399.00
Riveting towers.....	402.50
Filling bases of posts...	11.00
Erecting girder spans.....	402.50
Riveting girder spans.....	264.00
Framing ties.....	130.75
Laying floor	222.25
Painting, first coat.....	204.37
Painting, second coat.....	180.25

Total labor.....\$2,521.00

Coal for derrick engine	120.00
Blacksmith coal.....	45.00
Train service, 5 days, at \$25.....	125.00
Wear of tools.....	125.00

Total, 500 lin. ft., at \$6.....\$2,936.00

Summary per ton—**Per ton.**

General expense, \$304.....	\$0.90
Erecting and riveting, \$1,479.....	4.32
Painting, 2 coats, \$385.....	1.13
Framing and laying floor, \$353.....	1.05

Total labor.....\$7.40

Coal, \$165.....	0.48
Train service, \$125.....	0.37
Wear of tools, \$125.....	0.37

Grand total.....\$8.52

The cost of framing and laying the floor, it will be seen, was \$353, or 70 cts. per lin. ft.

The total cost of this viaduct to the railway company was as follows:

Steel superstructure, labor.....	\$ 4,240
Steel superstructure, materials.....	19,000
Masonry substructure, labor.....	4,360
Masonry substructure, materials.....	5,200
Total	\$32,800

This is equivalent to \$45.50 per lin. ft. for superstructure, and \$19.10 per lin. ft. for substructure, or \$65.60 per lin. ft. of viaduct. The substructure, therefore, cost 30% of the total. Since the steel superstructure weighed 340 tons, or 680,000 lbs., it cost 3.56 cts. per lb. in place. As previously stated, the average height of this viaduct was 63 ft.; its maximum height was 89 ft. from top of masonry to base of rail. It was supported by 6 towers (or 12 bents), the length of the "tower spans" being 31 ft. The remaining spans, or "open spans," were three spans of 57 ft., two of 38 ft., and two of 30 ft. The above costs for labor include contract price for erection, salaries of engineers, inspectors, etc. The costs for materials include freight and train service.

Cost of Erecting a 580-ft. Viaduct.—This viaduct was erected by contract, with the same gang as the 500-ft. viaduct just described. The weight of the steel was 382 tons, or 764,000 lbs. The profile area was 34,800 sq. ft., the average height was 60 ft., and the maximum height from masonry to base of rail was 89 ft. There were 7 towers or 14 bents. The "tower spans" were 31 ft. The "open spans" were: One 61-ft. span, three 57-ft., one 38-ft., and three 30-ft. spans.

The cost to the contractor was as follows:

Time traveling—

2 days at \$5.00	\$10.00

Grand total.....\$3,606.25

Summary of cost per ton—**Per ton.**

General expense, \$227.....	\$0.59
Erecting and riveting, \$1,665.....	4.36
Painting, 2 coats, \$603.....	1.60
Framing and laying floor, \$698 ..	1.83

Total\$6.38

Coal, \$117.....	0.30
Train service, \$125.....	0.33
Wear of tools, \$160.....	0.42

Grand total.....\$9.43

Comparing this with the cost of erecting the 500-ft. viaduct, we see that the painting cost 50% more per ton, and that the work on the floor (timber deck) cost 80% more. In this 580-ft. viaduct the total labor on the deck cost \$698, or \$1.20 per lin. ft., which is fully double what it should have cost.

The total cost of this 580-ft. viaduct to the railway company was as follows:

Steel superstructure, labor.....	\$ 5,750
Steel superstructure, materials.....	21,950
Masonry substructure, labor.....	5,260
Masonry substructure, materials.....	4,240

Total\$37,800

This is equivalent to \$47.80 per lin. ft. for superstructure and \$19.70 per lin. ft. for substructure, or \$67.50 per lin. ft. of viaduct. Therefore the substructure cost 20% of the total. The steel superstructure cost 3 63 cts. per lb. in place.

Cost of a 1,170-ft. Viaduct.—This steel viaduct had profile area of 97,200 sq. ft. and an average height of 78½ ft. It had 12 towers and 2 "rocker bents," making a total of 26 bents. The extreme

height of bent from top of masonry pedestals to base of rail was 104 ft.; the average height 77 ft.; and the aggregate height of all bents, 2,000 ft. There were 12 plate girder "tower spans" of 31 ft. over the towers, 11 plate girder "open spans" of 61 ft., and 4 girder "open spans" of 31 ft.

The weight of the metal was 1,690,000 lbs.

The actual cost of erecting the viaduct was \$8.50 per ton. The viaduct was built and erected by a contractor at the following cost to the railway company for materials and labor:

874,000 lbs. girder spans in place, at 2.9 cts....	\$ 25,286
1,004,000 lbs. bents and towers, 3.2 cts.....	39,156
5,400 lbs. sheet lead, at 6 cts.....	324
132,000 ft. B. M. in floor system, at \$23.....	3,300

Total superstructure.....\$ 68,066

1,000 cu. yds. dry excavation, at 40 cts.....	4,000
640 cu. yds. wet excavation, at \$2.....	1,280
216,000 ft. B. M. sheet piling, etc., in cofferdams, at \$25	5,325
8,000 lin. ft. piles delivered and driven, at 30 cts.	2,420
3,000 cu. yds. riprap, at \$1.50.....	4,500
1,800 cu. yds. concrete, at \$8.....	14,400
1,800 lbs. iron in anchor bolts, etc., at 4 cts...	72

Total superstructure.....\$ 32,007

Engineering, shop inspection, etc..... 5,500

Grand total.....\$105,573

The cost per lin. ft. of viaduct was:

	Per lin. ft.	Per cent.
Superstructure	\$53.13	64.3
Substructure	27.36	30.4
Engineering	4.77	5.2
Totals	\$90.25	100.0

The foundations of two of the towers, eight masonry pedestals in all, were in water, which ran up the total cost of substructure very considerably. Nevertheless, the cost of the substructure of the majority of steel viaducts of large size is usually a far higher percentage of the total cost than it should be. This is due to the fact that bridge engineers are generally very painstaking in the economic design of superstructures and not so painstaking in the design of substructures. Because the design of a superstructure is an exact science, there is an attractiveness about such work easy to understand. Because the design of foundation is merely by rule of thumb, there is less of fascination in the work. This particular viaduct is a splendid example of our contention that engineers usually put altogether too little brains into designing substructures.

The concrete pedestals of the substructure rest on rock, with the exception of eight pedestals which have pile foundations. Yet every one of these concrete pedestals is designed exactly as if it were intended to rest on soft earth, as is shown in Fig. 15. It will be

seen that each pedestal has a base of 110 sq. ft. Even at a point where the viaduct is 90 ft. high, as in this case, the weight of the steel is less than 1,700 lbs. per lin. ft. The timber floor system would add only a little more than 300 lbs. per lin. ft., making a total of 2,000 lbs. Adding a live load of 5,000 lbs. per lin. ft. to this, we have 7,000 lbs. per lin. ft. Each bent has to support the weight of 45 lin. ft. of bridge, or $45 \times 7,000 = 315,000$ lbs. But this is distributed over two pedestals, making a load of 160,000 lbs. per pedestal, or 80 tons. If wind pressure were to raise this to 110 tons, the load on the foundation would be 1 ton per sq. ft., for we have 110 sq. ft. of foundation area.

From this it is clear that, even where resting on earth, the area of the pedestal base is in excess of any reasonable requirement.

Fig. 15.—Pedestals for Steel Viaduct.

Reid's "Concrete and Reinforced Concrete Construction," p. 408, gives the safe bearing power of soft clay at 1 ton per sq. ft., and of ordinary loam at 3 tons. Hence the absurdity of providing any such area of base as in this pedestal under discussion, for it is resting not on earth but on rock. It is perfectly clear that the designer could have saved 60 or 70% of the concrete masonry in each of these pedestals, had he not followed a rule of thumb which is applicable only to foundations resting on earth, and not always applicable even to them.

It is no unusual thing for earth to be called upon to support 10 tons per sq. ft., and there are few places where 5 tons can not be safely imposed on each square foot. A bridge engineer who is seeking to effect every possible economy should visit the site of every large structure, and personally test the bearing power of the earth, by digging test pits to the proposed depth of foundation where possible.

Another noticeable economic defect in the design of these pedestals is the excavation of the rock so as to form a square footing. Solid rock having so slight a transverse slope as that shown in the illustration need not be excavated at all. A few drill holes, in which large dowel pins are placed, will serve every purpose in providing against possible sliding of the masonry on the ledge rock under the vibration of passing trains.

Cost of the Pecos Viaduct.*—The Pecos Viaduct, Texas, was built in 1891 for the Galveston, Harrisburg & San Antonio Ry. It is a single track steel viaduct 2,180 ft. long, and 321 ft. high at the center. The viaduct is built on a peculiar profile. For 1,070 ft. of the west end the average height of the viaduct is 57 ft., then the ground drops off precipitously, so that for a distance of 600 ft. the towers are 260 ft. high and rest on masonry piers, of varying heights up to 80 ft. Then the ground rises on an almost uniform slope to the last pier on the east end. The profile area between the base of rail, and the tops of masonry piers is approximately 280,000 sq. ft. Dividing this by the length gives 129 ft. as the average height of the viaduct. None of the tower piers is under water at times of low water, but three of them are submerged at times of high water. There are 31 towers and the tower spans are plate girders 35 ft. span. The spans between the towers are 8 riveted lattice girder spans of 65 ft., 2-pin-connected cantilever spans of 172 ft., and one 80 ft. suspended span. The masonry piers were built in 229 working days. The steel work was erected in 118 days, including 24 days required to build a traveler weighing 116 tons and 6 days to take it down and move it to the opposite side of the river. The erecting gang average 60 men and at no time exceeded 79. The average amount of steel erected were 41,000 lbs. per day for the 86 days, or 39,800 lbs. per day for the 118 days. If wages were \$2.50 a day, this would be equivalent to 0.36 ct. per lb.; exclusive of the cost of erecting and moving the traveler, or 0.5 ct. per lb. including erecting and moving the traveler. The actual wages paid are not available but were apparently considerably more than \$2.50, for the actual cost of erecting this viaduct was 0.37 ct. per lb. including not only the cost of erecting the traveler but the cost of the traveler itself.

The weight of this viaduct was as follows:

	Lbs.
31 plate girder spans, 35 ft. long.....	495,550
1 plate girder span, 35 ft. long.	24,810
8 lattice girder spans, 65 ft. long.....	354,120
1 lattice girder span, 80 ft. long.....	57,870
2 cantilevers, 172½ ft. long.....	473,400
Floor bolts and railings.....	51,620
Total superstructure	1,462,370
Towers and anchor bolts.....	2,147,190
Grand total	3,609,560

*Engineering-Contracting, Dec. 3, 1903.

The cost was as follows:

3,270 cu. yds. masonry, at \$13.....	\$ 42,505
3,609,560 lbs. steel delivered, at 4.43 cts.	160,000
Erecting, including cost of traveler.....	30,500
256,600 ft. B. M. timber flooring, at \$20 75	5,325

Total\$238,330

This is equivalent to \$119 per lin. ft.; and the weight of steel was 1,650 lbs. per lin. ft.

It will be noted that the masonry pedestals cost only 18% of the total cost of the viaduct.

Cost of the Marent Viaduct.*—In 1884 a single track iron viaduct was built for the Northern Pacific Ry. across Marent Gulch to replace a timber viaduct. The profile area of this viaduct is 95,700 sq. ft. below the top of the stringers, and the length of the viaduct is 800 ft., so the average height is practically $95,000 \div 800 = 120$ ft. nearly. It has two towers, each 200 ft. high; two towers each 120 ft. high; and four short bents.

There are 4 plate girder spans at the ends, each 30 ft.; 5 truss spans, each 116 ft. long; girders 23 ft. long over each of the four towers. The foundation piers are of concrete, of which there was 544 cu. yds. in all. The viaduct contained the following amount of iron and steel:

	Lbs.
Towers and bents.....	872,900
5 deck truss spans.....	468,700
Floor system.....	297,827
4 plate girder spans.....	40,161
Miscellaneous	8,962

Total, at 2,133 lbs. per lin. ft.....1,686,550

This is equivalent to 17.6 lbs. per sq. ft. of profile area.

The iron work cost 3.85 cts. per lb. delivered at St. Paul, and the "traffic charges" for transporting the iron and other materials from St. Paul, at 1 ct. per ton mile, amounted to \$24,743.

The total cost was:

Foundations	\$ 21,664.59
Masonry	30,079.81
Towers, materials and labor.....	49,188.44
Superstructure, materials and labor...	36,593.94
Timber, floor.....	4,701.43
Painting	1,826.74
Permanent track.....	116.06
Engineering and incidentals.....	9,086.15
Permanent track.....	116.06

Total\$153,362.16

Traffic charges..... 24,743.18

Total, at \$222.63 per lin. ft.....\$178,105.34

*Engineering-Contracting, Dec. 2, 1908.

The cost of erecting the towers was \$15,800, and of erecting the superstructure (spans and floor) was \$8,500, or a total of \$22,300 for erecting 840 tons, or nearly \$27 per ton. This exceedingly high cost is said to have been due to high wages and to working in the winter. It appears, however, to have been due to the usual laxness of men doing "company work."

The following were the quantities in the substructure, including the abutments:

	Cu yds.
Rock excavation.....	1,445
Earth excavation	3,689
Concrete	544
Cut stone masonry.....	722

It cost \$7,664 to remove the old wooden viaduct, which contained 970,000 ft. B. M., or about \$7.70 per M. for removing this timber.

Skilled labor received \$2 to \$4.50 a day. The cost of erecting and removing the temporary buildings in which the men lived was \$2,700. Depreciation on plant was estimated at \$4,500. Both these items are included above.

For comparison, the following weights of a viaduct of the same average height are given by Mr. H. G. Tyrrell. The weight of a single track railway viaduct 120 ft. high, with tower bents 30 ft. c. to c., and intermediate girder spans of 60 ft. was:

	Wt. per lin. ft.
Spans	622 lbs.
Bents	955 lbs.
Traction bracing.....	324 lbs.
Total	1,941 lbs.

Taking the cost of steel in place at $3\frac{1}{2}$ cts. per lb. for girders and 4 cts. per lb. for bents and bracing, the cost per lin. ft. is \$75 for the steel. To this must be added the cost of the concrete pedestal piers.

Cost of the Old Kinsua Viaduct.—Mr. Thomas C. Clark gives the following data relative to the original Kinsua viaduct built in 1882:

The viaduct was 2,050 ft. long, 302 ft. high at the center, and weighed only 1,400 tons, or 7.36 lbs. per sq. ft. of profile area. It was designed for a live load of an 80 ton consolidation engine followed by a train of 8,000 lbs. per lin. ft. Rough calculations from a small profile indicate that the profile area was about 380,000 sq. ft. below the base of rail. The viaduct was erected by a gang of 40 men in 4 mos., using one traveler. The iron work was delivered at only one end of the ravine, and slid down along a trough to a point below the traveler. The tower girders were $28\frac{1}{2}$ ft. long, and the intermediate girders 61 ft. long. Mr. Clark claims that the first American viaduct was designed by C. Shaler Smith, the viaduct being really a high trestle with iron posts. Mr. Clark, in 1870, designed the first modern type of viaduct, consisting of braced towers supporting intermediate girders.

Mr. Clark states that the cost of erecting the Kinsua viaduct was less than \$12 per ton, which is equivalent to \$16,800 for erecting

the entire viaduct. This does not agree very well with his statement that 40 men erected it in 4 mos., for that would be about 4,000 man-days, and it is not likely that any such wages at \$4 a day were paid, unless the height at which the men worked led to a demand for high wages. If wages averaged \$2.50 a day, the labor cost would have been about \$7 per ton. As a matter of fact this same viaduct was removed in 1900 and a new one built in its place, the cost of erection (including removal of the old viaduct) being given below.

Cost of the New Kinzua Viaduct.—Mr. C. R. Grim gives the following data about the Kinzua viaduct on the Erie R. R., in McKean County, Pa. It was built in 1900 to replace an iron viaduct built 19 years before. The viaduct is 2,053 ft. long, rests on the old piers, and has 20 towers, ranging from 30 to 285 ft. high from masonry to base of rail, and has a profile area of about 380,000 sq. ft. below the base of rail.

The weight of the deck spans is 638 tons, and that of the towers is 2,715 tons, total 3,353 tons. Two travelers were used, working from opposite ends. Each traveler spanned a clear space of 160 ft., having an old tower in the middle. The work of removing the old viaduct and erecting the new one consumed 4 mos., with a force of about 120 men at 10 hrs. a day. Charging the entire cost against the new viaduct, and assuming that wages averaged \$2.50 a day, the labor cost would be about \$30,000 or \$9 per ton. The weight was about 17.4 lbs. per sq. ft. of profile area.

Weight of a Steel Viaduct.—A single track steel viaduct was built in 1904 near Paoli, Ind., for the Chicago, Indianapolis & Louisville Ry. It is 370 ft. long, and 37 ft. high in the center. It has 2 abutments and 36 small pedestal piers, four under each tower. The abutments are 60 ft. high. The pedestal piers are $3\frac{1}{2}$ ft. square on top and extend down to solid rock, a distance of 3 to 12 ft. below the ground. There are 4,300 cu. yds. masonry in piers and abutments, and 1,091,000 lbs. steel and cast iron in the viaduct.

Data on Riveting a Viaduct.—In the construction of the Cuyahoga Valley Viaduct, there were 18,869 seven-eighths inch rivets driven in the field. The average day's work for a gang of 4 men was 192 rivets. The best day's work was 315, all hand driven. The defective rivets amounted to less than 2 per cent.

Cost of Concrete Pedestals for a Steel Viaduct.—The viaduct was 410 ft. long with towers 30 ft. high on the Canadian Northern Ontario Ry. The concrete work consisted of $10 \times 10 \times 4$ -ft. footings carrying pedestals 5×5 ft. on top with sides battered 1 in 12 to meet the footings. The tops of the pedestals were all at the same elevation but their height varied, the highest being 18 ft. above tops of footing. The pedestals were cored for anchor bolts. The total amount of concrete in the work was $711\frac{1}{2}$ cu. yds., of which $298\frac{1}{2}$ cu. yds. were in the footings and 405 cu. yds. were in the pedestals. The concrete was a $1-2\frac{1}{2}-4$ mixture, taking $1\frac{1}{2}$ bbls. cement for the footings; and a $1-2\frac{1}{2}-4$ mixture, taking $1\frac{1}{4}$ bbls. cement for the pedestals. Altogether 3,350 bags of cement were

used for the 711½ cu. yds. of concrete, including 44 bags for the 1-2 mortar top dressing and 15½ bags for washing, plastering, etc.

Excavation.—The pits for the footings were 12 ft. square carried down into hard clay through 5 or 6 ft. of sand and clay and a 1-ft. layer of driftwood. The average depth of pit was 11½ ft., the maximum depth 15.2 ft. The material was handled by a horse-power derrick, consisting of a guyed mast and a boom set at 45°. The bucket was lifted by a double purchase block, the fall of the line being carried to a pulley set a few feet to one side of the mast and thence to a whiffletree. This gave enough side pull on the boom to swing the bucket clear of the excavation. To hold the boom fixed during hoisting and lowering, a line from the end was carried to the far side of the excavation and operated by one man. One man drove the horse. Two ¼-cu. yd. buckets were employed, one being filled as the other was being dumped. There were 1,127 cu. yds. of excavation which cost as follows:

Items	Total	Per cu. yd.
General expenses	\$194	\$0.172
Foreman, 35 days at \$3.....	105	0.093
Labor, 323 days at \$1.60.....	517	0.456
Horse, 26 days at \$2.....	52	0.046
Totals	\$868	\$0.769

Forms.—The forms for the footings were rough 2-in. lumber braced to the pit walls. The pedestal forms were made of 2-in. dressed lumber. Five sets were made. Each form was made 16 ft. high and was added to at the bottom for the taller pedestals and cut off for the shorter pedestals, which were built last. Two sides of each form were built in panels or units, and the two other sides were built up board by board as the concreting progressed. The solid panel sides were held together by two wire ties every 3 ft. in height; one tie every 3 ft. held the other two sides. These ties were No. 9 gage wire looped around studs and tightened by twisting. There were also core forms for the anchor bolts, each a box 4 ft. long, 6 ins. square on top and 5½ ins. square on the bottom. The cost of the forms was as follows:

Lumber—	Total	Per cu. yd.
7,000 ft. B. M. 2-in. derrick at \$19 per M.....	\$133	
2,000 ft. B. M. 2-in. rough at \$18 per M.....	36	
750 ft. B. M. 2x4-in. scantling	14	
Cartage, \$2.50 per M. ft.....	24	
Anchor bolt boxes, etc.	10	
Totals	\$217	
Deduct salvage \$10.....	\$207	\$ 0.19
Wire, Ties, Nails—		
5 rolls No. 9 at 3 cts.....	\$ 12	
200 lbs. wire nails at \$2.50.....	5	
Totals	\$ 17	\$0.024

Labor—

Carpenter, 28 days at \$2.50.....	\$ 70	
Helpers, 38 days at \$1.75.....	67	
Totals	\$137	\$0.193
Grand totals	\$361	\$0.507

Concrete.—The concrete was mixed by hand on "boards" set close to the piers and was shoveled directly into the forms. The materials were transported to the boards in wheelbarrows. A gang of 1 foreman, 5 barrowmen, 8 mixers and 1 man in the form averaged 25½ cu. yds. per day, or a little over 2 cu. yds. per man working. The maximum day's work was 38 cu. yds. with 16 men. The concrete was deposited moderately wet and the mortar was spaded to the surface. The top 3 ins. of the pedestals was built of 1-2 mortar. The exposed surface of the piers was washed with a thin cement grout; about 1 bag of cement was required for 25 sq. yds. of surface. One man covered 7½ sq. yds. per hour, using an ordinary whitewash brush. The cost of the concrete work was as follows:

Materials—	Total.	Per cu. yd.
173 cu. yds. rubble stone at \$0.85.....	\$ 147	\$ 0.207
556 cu. yds. 2-in. stone at \$1.875.....	1,041	1.463
290 cu. yds. sand at \$1.25.....	363	0.510
840 bbls. cement at \$1.80.....	1,512	2.121
Cartage at 15 cts. per bbl.....	126	0.163
Totals	\$3,190	\$ 4.464
Labor—		
Foreman, 28 days at \$4.....	\$112	\$ 0.157
Laborers, 343 days at \$1.75.....	600	0.843
Totals	\$712	\$ 1.000

General Expenses.—General expenses were as follows:

Superintendence	\$239.50
General labor	78.40
Interest and depreciation on plant tools...	70.50
Total	\$388.40

This gives a charge of 27.3 cts. per cubic yard of concrete.

There were also the following items of cost:

24 M. ft. B. M. 6x8-in. hemlock at \$20.....	\$480
Labor backfilling piers	162
Platforms, runways, etc.....	69
Total	\$768

We can summarize the cost of concrete work as follows:

	Per cu. yd.
General expenses (½ of \$388).....	\$0.273
Platforms, runways, etc.	0.097
Forms	0.507
Labor	1.000
Materials	4.464
Total	\$6.341

Mr. J. H. Ryckerman is authority for the above data.

Cost of Abutments and Pedestal Piers, Lonesome Valley Viaduct.—Mr. Gustave R. Tuska gives the following on the concrete substructure of the Lonesome Valley Viaduct, near Knoxville, Tenn. There were two U-shaped abutments and 36 concrete pedestal piers made of a light limestone that deteriorates rapidly when used for masonry. Derricks were not needed as would have been the case with masonry piers, and colored labor at \$1 for 11 hrs. could be used. The piers were made 4 ft. square on top, from 5 to 16 ft. high, and with a batter of 1 in. to the foot. The abutments average 26 ft. high, 26 ft. long on the face, with wing walls 27 ft. long; the wall at the bridge seat is 5 ft. thick, and the wing walls are $1\frac{1}{2}$ ft. wide on top. Batters are 1 in. to the foot.

The forms were made of 2-in. tongued and grooved plank, braced by posts of 2 x 10-in. plank placed 2 ft. c. to c. for the abutments, and at each corner for the piers. At the corners one side was dapped into the other, so as to prevent leakage of cement. The posts were braced by batter posts from the earth. For the piers a square frame was dropped over the forms and spiked to the posts. The abutment forms were built up as the concreting progressed. The north abutment forms were made in sections 6 ft. high, held by $\frac{1}{2}$ -in. bolts buried in the concrete. The lower sections were removed and used again on the upper part of the work, thus saving plank. The inside of forms was painted with a thin coat of crude black oil. The same form was used for several piers.

The concrete was 1:2:5, the barrel being the unit of measure, making about $\frac{3}{4}$ cu. yd. of concrete per batch. The mortar was mixed with hoem, but shovels were used to mix in the stone. By passing the blade of a shovel between the form and the concrete, the stone was forced back and a smooth mortar face was secured. Rammers weighing 30 to 40 lbs. were used for tamping. Two days after the completion of a pier the forms were removed. The concrete was protected from the sun by twigs, and was watered twice a day for a week. It was found by actual measurement that 1 cu. yd. of concrete (1:2:5), the ingredients being measured in barrels, consisted of $1\frac{1}{2}$ bbls. of Atlas cement, 10 cu. ft. of sand and $26\frac{1}{2}$ cu. ft. of stone. The total amount of concrete was 326 cu. yds. of which two-thirds was in the two abutments. The work was done (in 1894) by contract, for \$7 per cu. yd., cement costing \$2.80 per bbl., sand 30 cts. per cu. yd., and wages \$1 a day. A slight profit was made at this price. A gang of 15 men and a foreman would mix and lay about 40 cu. yds. in 11 hrs. when not delayed by lack of materials. The cost of making the concrete, with wages at \$1 a day, was:

	Cents per cu. yd.
1 man filling sand barrels and handling water.....	2.7
2 men filling rock barrels	5.4
4 men mixing sand and cement.....	10.6
4 men mixing stone and mortar.....	10.6

	Cents per cu. yd.
2 men wheeling concrete.....	5.3
1 man spreading concrete in place	2.7
1 man tamping	2.7
Total labor	40.0
1 foreman at \$2	5.6
Total exclusive of forms	45.0

If wages had been \$1.50 a day instead of \$1, the labor cost would have been 68 cts. per cu. yd.

Cost of Paint.—Mr. Walter G. Berg, Chief Engineer of the Lehigh Valley R. R., gives the following on painting iron railway bridges:

Oxide of Iron.

6½ lbs. oxide of iron, at 1 ct.....	\$0.06
5/8 gal. (6½ lbs.) raw linseed oil, at 56 cts.....	0.47
Cost of 1 gal. of paint	\$0.53

Red Lead.

20 lbs. red lead, at 5 cts.....	\$1.00
¾ gal. (5½ lbs.) raw linseed oil, at 56 cts.....	0.42
Cost of 1 gal. of paint	\$1.42

Graphite.

2½ lbs. graphite paste, at 12 cts.....	\$0.45
¾ gal. boiled linseed oil, at 59 cts.....	0.45
Cost of 1 gal. of paint	\$0.90

Weight and Surface Area of Steel Bridges.—Mr. C. E. Fowler, Chief Engineer Youngstown Bridge Co., gives a table of the weights of iron highway and single track bridge trusses, and the corresponding areas of metal requiring painting, as determined "by actual calculation in a large number of cases." I find by a study of the tables that they can be very simply expressed in rules or formulas, as follows: For a highway bridge divide the weight of metal in pounds by 7 to get the area of metal surface in square feet. This applies to highway bridges 16 ft. wide, calculated for a floor load of 90 lbs. per sq. ft., for all spans from 40 to 300 ft. For a single track railway bridge, divide the weight of metal in pounds by 12 to get the area of metal surface in square feet.

The weight in pounds of metal in a highway bridge is found by adding 50 to 2 times the span in feet and multiplying this sum by the span in feet. Expressed in a formula this rule is $w = L(2L + 50)$.

The weight in pounds of metal in a single track railway bridge is found by adding 400 to 4.8 times the span in feet and multiplying this sum by the span in feet. $w = L(4.8L + 400)$.

Cost of Painting a Howe Truss Bridge.—The bridge was painted with two coats of paint costing \$1 per gallon. One gallon covered 133 sq. ft., two coats thick, and a painter averaged 166 sq. ft., two

coats thick, per 10 hrs., or 333 sq. ft. of one coat per day. The cost was, therefore, as follows:

	Cts. per sq. ft.	Cts. per sq. yd.
Paint, two coats	0.75	6.8
Labor painting, two coats (17½ cts. per hr.)	1.15	10.3
Total	1.90	17.1

Cost of Painting 6 R. R. Bridges.—Three spans pin-connected Pratt truss bridges, each 145 ft. long, 14 ft. wide and 20½ ft. high, were painted with one coat at a cost of \$48 per span for labor. One span required 35 gals. of asphaltum paint costing 65 cts. per gal. The other spans received 27 gals. of carbon paint each, at \$1.50 per gallon.

A riveted Pratt truss bridge, 94 ft. long, 14 ft. wide and 20 ft. high was given one coat of black carbon paint, 23 gals., at \$1.50 per gal. The labor was \$40.

A double-intersection riveted lattice truss bridge, 96 ft. long, 14 ft. wide and 20 ft. high, was repainted with one coat of carbon paint, 26 gals., at \$1.50 per gal. The labor cost \$46.

A single intersection lattice truss highway bridge (20-ft. roadway and two 8-ft. sidewalks), 106 ft. long, was painted with one coat of black carbon paint, 35 gals., at \$1.25 per gal. The labor cost \$59.

Cost of Painting 6 R. R. Bridges and 2 Viaducts.—Mr. O. E. Selby, in Trans. Am. Soc. C. E., 1897, has a paper on the cost of painting the Louisville and Jeffersonville Bridge across the Ohio River. The work was begun June 3, and finished Aug. 7, 1893. There was practically no traffic over the bridge during the work, which, of course, lessened the cost of painting; and the iron being new required no great amount of cleaning. The force averaged about 50 men with 1 foreman, 1 assistant foreman and 1 time-keeper. The men were mostly ordinary bridge men, erectors and carpenters, and were paid \$2 a day of 10 hrs. Some few men painting sidewalk railings and other parts not hazardous were paid \$1.50 a day. The paint was oxide of iron, and was used just as it came from the barrel, except for a little occasional thinning, equivalent to about ¼ gal. per bbl. of paint. The cost of the paint was 67 cts. per gal. The best results were obtained with flat brushes costing \$7.50 per doz., of which 19 doz. were used; 4 doz. steel brushes and 13 doz. whisk brooms were used for cleaning the iron. The total cost of the work was: Paint, \$3,769; labor, \$4,427; equipment, \$301; accident insurance, \$200; total, \$8,697 distributed as follows:

Jeffersonville Approach (Viaduct) and Span No. 1 (4,271 Ft. Long; 1,762 Tons). Per ton.

0.62 gallon iron oxide paint.....	\$0.43
Labor, \$2 per 10 hrs.	0.51

Total per ton of 2,000 lbs.	\$0.93
Total per lin. ft.	\$0.38

This Jeffersonville approach is a viaduct having an average height of 40 ft. and a length of 4,063 ft., all single track, except 1,000 ft., which is double track. Span No. 1 is single track, 209 ft. c. to c. The Jeffersonville approach had previously been painted with one coat in October, 1892. The work of which costs are above given consisted in going over the viaduct, cleaning and painting all spots where rust had formed; then after this had dried the whole viaduct was given one coat.

Louisville Approach (2,585 Ft. Long; 1,012 Tons). Per ton.

0.90 gallon paint, first coat.....	\$0.61
0.58 gallon paint, second coat.....	0.29
Labor on first coat.....	0.72
Labor on second coat.....	0.38

Total per ton.....	\$2.10
Total per lin. ft.....	\$0.82

This Louisville approach is 2,585 ft. long, single track, and has an average height of 45 ft. It had been erected a year before it was painted, and had never been painted before. It received two coats throughout.

Bridge Spans Nos. 5 and 6 (Each 338 ft. c. to c.; Total Weight 665 Tons). Per ton.

0.66 gallon paint, first coat.....	\$0.44
0.44 gallon paint, second coat.....	0.30
Labor on first coat.....	0.47
Labor on second coat.....	0.35

Total per ton of 2,000 lbs.....	\$1.56
Total per lin. ft.....	\$1.52

Bridge Spans Nos. 2, 3 and 4 (Each Span 546½ ft. c. to c.; Total 2,768 Tons). Per ton.

0.50 gallon paint, first coat.....	\$0.33
0.32 gallon paint, second coat.....	0.22
Labor on first coat.....	0.32
Labor on second coat.....	0.22

Total per ton of 2,000 lbs.....	\$1.09
Total per lin. ft.....	\$1.84

All these bridge spans were single track, erected about a year before they were painted. All the iron had had a shop coat of linseed oil. All the spans were given two coats of paint throughout, except the inside of the top chords and end posts which received only one coat, as it was believed that this one coat in such a protected location would outlast the two coats on exposed work.

Spans Nos. 5 and 6 were erected in the latter part of 1893, while the other and longer spans were erected a year later, so that the rustier condition of Nos. 5 and 6 may account for their taking more paint.

The labor cost of painting 5,700 lin. ft. of sidewalk railings was \$390, or \$0.68 per 100 ft. This does not include the cost of the paint, which was a small item. Half of this railing was a lattice railing 4 ft. high; the other half was a gas pipe railing consisting of two lines of 1¼-in. gas pipe.

Cost of Painting 50 Plate Girder Bridges.—Mr. W. J. Wilgus gives the following data on the cost of repainting 33 steel bridges on the Rome, Watertown & Ogdensburg R. R. in 1896-8. The bridges were originally painted with two coats of "patent paint" that had failed within a year. The following costs include cleaning with wire brushes, and repainting with one coat of asphaltum-varnish paint made of 4 lbs. lampblack ground in pure raw linseed oil, $\frac{1}{4}$ gal. genuine asphaltum varnish, $\frac{1}{4}$ gal. pure boiled linseed oil, and $\frac{1}{4}$ gal. drying japan. This paint cost 60 to 80 cts. per gal., and 1 gal. covered 350 sq. ft. Labor cost \$2 a day.

The calculation of the exposed areas of many of the plate girder bridges showed that there were 100 sq. ft. for every ton of 2,000 lbs.

Cost of Painting 50 Plate Girder Spans (Av. Length, 74 ft.; Total Weight, 1,884 Short Tons).

	Per ton.
0.30 gal. paint	\$0.175
Labor cleaning and painting.....	0.340

Total per ton\$0.515

Cost of Painting 5 Truss Spans (Av. Length, 155 ft.; Total Weight, 638 Tons).

	Per ton.
0.39 gal. paint	\$0.235
Labor cleaning and painting.....	0.490

Total per ton\$0.725

Cost of Painting 11 Spans of a Viaduct (Total Length, 706 ft.; Height, 88 ft.; Weight, 342 Tons).

	Per ton.
0.48 gal. paint	\$0.39
Labor cleaning and painting	0.60

Total per ton\$0.99

Cost of Cleaning and Painting 10 Bridges.—Mr. E. D. Graves gives the following data on the painting of light double triangular trusses in bridge spans from 80 to 136 ft., the total length being 1,000 ft. painted in the summer of 1897. The steel work had received one shop coat of iron oxide paint, and had been in place one year. The greater part of the surfaces was found to be scaled off and rusted. The surfaces were scraped with a steel scraper or brushed with a steel wire casting-brush. The dust was removed with a whisk broom, and one coat of No. 38 Detroit Graphite paint applied, costing \$1.10 per gallon, delivered. The floor beams and bottom chords being most likely to rust, were painted a second coat. The foreman received \$3.50 per day, and had 8 to 12 men, at \$1.75. These men were mostly laborers, except a few bridge men for the top work. The cost was as follows per ton of 2,000 lbs.:

Cost of First Coat—

	Per ton.
0.94 gal. first coat on 202 tons.....	\$1.04
Labor cleaning and painting 202 tons.....	1.44

Total per ton, one coat.....\$2.48

Cost of Second Coat (Bottom Chord and Floor Beams).

	Per ton.
0.35 gal. second coat on 100 tons.....	\$0.38
Labor painting second coat 100 tons.....	0.58

Total per ton of bottom chord and beams. \$0.96

The total cost of paint and labor was \$598, or nearly 60 cts. per lin. ft. of bridge.

Cost of Painting 48 Bridges and 2 Viaducts.—Mr. C. D. Purdon gives the following data: These bridges were new and painted with two coats of red lead. They had received one coat of oil at the shop.

	Cost per ton		
	Paint.	Labor.	Total.
Two deck girders, each 54 ft. (34.3 tons) ..	\$0.80	\$1.34	\$2.14
Pratt truss, 108 ft. (62.9 tons)	0.58	1.45	2.03
Pratt truss, 180 ft. (161.4 tons)	0.83	1.27	2.09
Six deck girders, each 54 ft. (105.2 tons) ..	0.65	1.12	1.77
Iron viaduct; two 64 ft., two 48 ft., and two 32 ft. deck girders (182.4 tons)	1.40	0.76	2.16
Iron viaduct, eight 64 ft., and seven 32 ft. spans (471 tons)	1.00	0.66	1.66
Pratt truss, dbl. track, 150 ft. (228.7 tons) ..	0.51	1.17	1.68

The summary of the amount of lead and oil used on the above bridges is as follows:

	Per ton	
	Lbs. of lead.	Gals. of oil.
Deck girders (139.5 tons)	6.08	0.48
Single track trusses (224.3 tons)	7.12	0.56
Viaducts (653.3 tons)	13.80	0.44
Summary of all (1,245.6 tons)	10.10	0.42

Judging from the amount of paint used, a truss bridge takes 1.2 times as much paint per ton as a plate girder, and a viaduct takes 2.3 times as much as a plate girder. This is confirmed on p. 560.

The cost of cleaning and painting 17 spans over the Arkansas River is as follows: These bridges received two coats of red lead and oil, having been originally painted with iron oxide which was first cleaned off. The cost of cleaning off the old paint is included, and almost equaled the cost of applying the first coat of red lead.

Cost of 9 Spans (153 Ft.; Weight, 810.6 Tons).

	Per ton.
7 lbs. red lead	\$0.49
Labor	0.58

Second coat—

2.3 lbs. red lead	0.17
Labor	0.26

Total per ton \$1.49

Cost of 8 Spans (Three, 253 Ft.; Four, 163 ft.; One Draw, 370 Ft.; Total Weight, 1,451.2 Tons).

First coat—	Per ton.
6 lbs. red lead	\$0.43
Labor	0.54
Second coat—	
1.9 lbs. red lead	0.15
Labor	0.26
Total per ton	\$1.37

The average of the above 17 spans was: 6.42 lbs. of lead and 0.23 gal. of oil per ton for the first coat; 2.04 lbs. of lead and 0.074 gal. of oil per ton for the second coat.

The cost of repainting 13 spans with two coats of iron oxide was as follows:

	—Gallons—		—Cost per ton—		
	Paint.	Oil.	Paint.	Labor.	Total.
200-ft. deck truss and two 50-ft. girders, dbl. track (475.6 tons)....	128	60	\$0.20	\$0.62	\$0.82
Pony lattice, 92½ ft. (115 tons)....	30	10	0.31	0.33	0.64
Three through spans, 150 ft. and 302 ft. draw span (656.7 tons).....	335	123	0.36	0.62	0.99
Three through spans, 150 ft. (313.3 tons)	184	46	0.33	0.54	0.92
Three through spans, 150 ft. (297.6 tons)	130	30	0.23	0.54	0.81

These 13 spans had originally been painted with iron oxide which was not cleaned off except at rusted spots.

It will be noted that about ¾ gal. of oil was used to thin each gallon of paint.

The cost of repainting ten old bridges with one coat of iron oxide was as follows:

	—Gallons—		—Cost per ton—		
	Paint.	Oil.	Paint.	Labor.	Total.
Double track truss, 126 ft. (176 tons)	75	25	\$0.19	\$0.55	\$0.74
Through plate girder, 50 ft. (27.6 tons)	15	3½	0.34	0.34	0.68
Six spans deck truss, 150 ft. (696.5 tons)	280	62	0.35	0.51	0.76
Deck plate girder, 70 ft. (30.4 tons) ..	13	..	0.20	0.22	0.44
Through plate girder, 47 ft. (24.5 tons)	17	..	0.32	0.34	0.66

These 10 spans had been originally painted with iron oxide which was not cleaned off except at rusted spots.

It will be noted that the average of these ten spans is 0.51 gal. of paint and oil per ton, for one coat work.

Cost of Cleaning and Painting Four Bridges, St. Louis.—Mr. N. W. Eayers gives the following data on painting railway bridges with one coat of carbon paint. This paint was ground especially for the bridge work, and came as "semi-liquid" taking about 1 gal. of oil to 1 gal. of "semi-liquid." It was laid on thick.

The St. Louis Merchants' Bridge is double track, three spans, each of 517½ ft., trusses 75 ft. deep at center. It was erected in 1890, and had had one shop coat and one coat of iron oxide after

erection. The metal was very rusty, and the cost of cleaning was quite large, but could not be separated from the cost of painting. The total cost of cleaning and painting these three spans in 1896 was as follows:

493 1/4 gals. boiled oil, at \$0.53.....	\$ 236.05
552 1/2 gals. carbon paint, at \$1.25.....	690.62
Sundry supplies.....	69.96
48 days' labor, at \$2.50.....	120.00
91.4 days' labor, at \$2.25.....	205.65
444.4 days' labor, at \$2.00.....	888.80
51.5 days' labor, at \$1.00.....	51.50
Total	\$2,812.61

The cost per lin. ft. was, therefore, \$1.49, and 0.69 gal. of paint, costing 93.3 cts. per gal., was required per lin. ft.

The Ferry St. Bridge is a double track deck span, 136 ft. resting on iron columns. It was cleaned and painted in 1896, at the following cost:

32 gals. boiled oil, at \$0.53.....	\$ 18.56
22 gals. carbon paint, at \$1.25.....	27.50
Labor	97.70
Total, at \$1.14 per lin. ft.....	\$143.76

The Angelica St. Bridge is a through plate girder bridge, 68-ft. span, having a total painted surface of 6,250 sq. ft., which required 1 gal. of paint for every 312 1/2 sq. ft. The cost was as follows:

10 gals. boiled oil, at \$0.53.....	\$ 5.30
10 gals. carbon paint, at \$1.25.....	12.50
Labor	22.00
Total, at \$0.59 per lin. ft.....	\$40.30

The Elevated Structure, Merchants' Bridge, consists of steel columns supporting plate girder spans of 28 to 35 ft., carrying a double track railroad. It was erected and painted in 1890, but in 1897 it was badly rusted and was repainted at a contract price of 57 cts. per ft. for 4,075 ft. The actual cost to the contractor was as follows:

Carbon paint and oil, one coat.....	\$ 748.13
Labor for cleaning.....	657.67
Labor for painting.....	628.74
Total, exclusive of foreman's time..	\$2,034.54

The St. Louis (Eads) Bridge was repainted in 1896. It consists of three arched spans of a total length of 1,524 ft., carrying a double track railway on the lower floor and a highway on the upper floor. The floor beams for the highway are the struts for the wind truss. The bridge is 54 ft. wide out to out. The metal was quite rusty, in places, requiring chipping to remove scale, especially the highway floor beams exposed to locomotive smoke. It

was painted with one coat. The cost was \$0.70 per ton distributed as follows:

675 gals. boiled oil, at \$0.35.....	\$ 236.25
650 gals. carbon paint, at \$1.25.....	812.50
Sundry supplies.....	52.55
Labor, 130 days, at \$2.50.....	325.00
246 days, at \$2.25.....	553.50
955 days, at \$2.00.....	1,910.00
Total, at \$2.55 per lin. ft.....	\$3,889.80

Cost of Painting Two Railway Bridges.—The following data on scraping and painting two railway bridges are given by Mr. A. S. Markley. The bridges were both painted in 1896, bridge No. 1 being painted during the summer and bridge No. 2 during October and November. The structures are viaducts with lattice columns and lattice struts in towers. The total number of tons of iron in bridge No. 1 was 719; in bridge No. 2 there was 154 tons of iron.

Bridge No. 1, first coat—

	Total.	Per ton iron.
Red lead, 3,560 lbs., at \$.049.....	\$174.44	\$0.242
Boiled oil, 177 gals., at .40.....	70.80	.098
L. black, 18 lbs., at .085.....	1.53	.002
Labor	558.29	.776
Total	\$815.16	\$1.118

Bridge No. 1, second coat—

Red lead, 2,395 lbs., at \$.049.....	\$117.35	\$0.163
Boiled oil, 160 gals., at .40.....	64.00	.089
L. black, 55 lbs., at .085.....	4.67	.006
Labor	372.08	.517
Total	\$558.10	\$0.775

Bridge No. 2, first coat—

Red lead, 500 lbs., at \$.049.....	\$ 24.50	\$0.159
B. L. oil, 18½ gals., at .40.....	7.40	.048
L. black, 5 lbs., .085.....	.43	.003
Labor	121.41	.758
Total	\$153.74	\$0.968

Bridge No. 2, second coat—

Red lead, 335 lbs., at \$.049.....	\$ 16.41	\$0.106
B. L. oil, 17 gals., at .40.....	6.80	.044
L. black, 10 lbs., at .08½.....	.85	.005
Labor	89.90	.584
Total	\$113.96	\$0.739

Summary—

	—Per ton iron.—	
	Bridge 1.	Bridge 2.
Labor	1.294	1.373
Labor and material.....	1.896	1.731
Material	\$0.403	\$0.359

Gallons boiled oil, second coat.....	.223	.110

Cost of Painting Plate Girders, Truss Bridges and Trestles on the C. & W. M. Ry.*—Table XIX gives the cost of painting several bridges on the Chicago & West Michigan Ry. (Detroit, Lansing & Northern R. R.), the work being done in 1894.

Cost of Painting, Cross-References.—For further data consult the index under "Painting."

Cost of Bridge Abutments.—Mr. W. A. Rogers gives the following data relative to the construction of bridge abutments on the C., M. & St. P. Ry.: The work consisted in building 20 abutments for 16 four-track plate girder bridges over street crossings in Chicago. The work was done between May 1 and Oct. 1, 1898, in which time 8,400 cu. yds. of concrete were placed, all the work being done by company labor. The forms were made of 2-in. plank and 6 x 6-in. posts bolted together at the top and bottom with $\frac{1}{2}$ -in. rods. The lumber was used over and over again. When the dressed plank became too poor for the face it was used for the back. The concrete was 1 Portland cement, 3 gravel and 4 to 4 $\frac{1}{2}$ limestone (crusher run up to 3-in. size.) A mortar face 1 $\frac{1}{2}$ in. thick was built up with the rest of the concrete. The concrete was made quite wet, and each man ramming averaged 18 cu. yds. a day rammed. The concrete was mixed by a machine of the Ransome type, operated by a 12-hp. portable gasoline engine. The load was very light for the engine, and 8 hp. would have been sufficient. The engine made 235 revolutions per minute, and the pulley wheels were proportioned so that the mixer made 12 revs. per min. One gallon of gasoline was used per hour, and the mixing was carried on day and night so as not to give the concrete time to set. The time required for each batch was 2 to 3 mins., and about $\frac{1}{2}$ cu. yd. of concrete was delivered per batch. The average output was 70 cu. yds. per 10-hr. shift, with a crew of 28 men; but as high as 96 cu. yds. were mixed in 10 hrs. The concrete was far superior to sand mixed concrete. The water for the concrete was measured in an upright tank and discharged by a pipe into the mixer. The sand and stone were delivered to the mixer in wheelbarrows, and the concrete was taken away in wheelbarrows. No derricks were used at all. Each wheelbarrow of concrete was raised by a rope passing over a pulley at the top of a gallows frame; one horse and a driver serving for this raising.

**Engineering-Contracting*, June 13, 1906.

TABLE XIX.—Cost of Painting Bridges.

Bridge.	Kind of Bridge.	Sq. yds. of Surface.	Weight in lbs.	Cost of Material.	Cost of Labor.	Total Cost.	Cost Per Sq. Yd.	Cost Per Ton.	No. lbs. Gal.
No. 150 7-10—Plate Girder.		100	11,700	\$3.58	\$7.07	\$10.56	\$0.10 1/2	\$1.80	20 3 1/4
No. 121 3-10—Plate Girder.		30	3,438	2.85	6.00	8.85	.11	2.10	16 2 1/2
		172	22,873	8.10	14.47	32.57	.13 1-10	1.97	25 4
		65	8,500	5.00	7.87	12.87	.20	3.00	20 4
		800	84,950	19.80	48.21	68.01	.08 1/2	1.72	90 14
		710	73,729	20.98	59.00	79.98	.11 1/2	2.16	85 13
		1,680	...	69.76	141.67	201.83	.12	...	260 40
		265	44,324	12.05	24.52	36.57	.14	1.65	50 8
		...	101,825	24.94	65.51	90.45	...	1.85	110 15

* New; required no cleaning. † Highway Pratt. ** 30-ft. girders. †† New.

A small gasoline hoisting engine would have been more satisfactory than the horse which was worked to its full capacity. After the barrows were raised (12 ft.), they were wheeled to the abutment forms and dumped. The empty wheelbarrows were lowered by hand, by means of a rope passing over a sheave and provided with a counterweight to check the descent of the barrow. The cost of the concrete (built by company labor) was as follows:

	Per cu. yd.
Cement, gravel and stone delivered.....	\$2.28
Material in forms (used many times).....	.11
Carpenters building and taking down forms.....	.24
Labor	1.18
Total per cu. yd.....	\$4.81

The labor cost includes moving the plant from one bridge to the next, building runways, gasoline for engine, oil for lights at night, and unloading materials as well as mixing, delivering and ramming the concrete. Wages were \$1.75 per 10-hr. day for laborers and \$2.50 for carpenters.

Data on Thirty-two Concrete and Reinforced Concrete Bridges (20 Highway and 12 Railway), Including Yardage, Cost, Etc.*—An engineer is frequently called upon to estimate the probable cost of a bridge before plans are drawn for the structure. In such cases it is very desirable to have at hand the cost of several similar structures as a guide to the judgment. It is also desirable to have a short description of each structure, and a statement of the quantities of material involved in its construction. With such data at hand an engineer, even though somewhat inexperienced, is not likely to go far wrong in his preliminary estimate of cost—his reconnaissance estimate, if you choose to call it so.

Valuable as such records of cost are for the purpose just indicated, they possess an additional value that should not be underrated—namely, as a guide in comparing the relative economy of the designs of two similar bridges. For this latter purpose it is desirable to have a record not merely of the total yardage of concrete in each bridge, but the distribution of that yardage in the various parts of the bridge. The yardage in the arch ring, the yardage in the spandrel walls, the yardage in the abutments, and so on, should be given, together with the weight of steel reinforcement in each of these groups of concrete yardage. Unfortunately, however, the published records of concrete bridges are almost invariably lacking in this respect, as will be noted in the following records.

In this connection, a word as to what every record should contain. The following dimensions should be given: The total length of the bridge over all, total length between abutments, length of barrel or true width of bridge, width of floor surface, width of road way or carriage way, width of side walks, clear span of arch and rise, thickness at crown and at spring line, height of abutments and piers up to the spring line, width of piers at spring line,

**Engineering-Contracting*, Sept. 2, 1902.

width of abutments at base, height of roadway above crown of arch, and ditto above low water.

When these dimensions are given, accompanied by a general description of the type of bridge and a detailed tabulated statement of quantities, the reader can form a very accurate idea of its general design.

In comparing the costs of any two concrete bridges, the first step should be to ascertain the cost per lineal foot measured between abutments. If there are several arches in series, the same holds true. If the bridges are single or double track railway structures a direct comparison of costs is then possible, but if they are highway bridges, it is necessary to ascertain the cost per square foot of floor area, for highway bridges differ so greatly in width. This floor area should not be estimated for the total length of the bridge over all, but only for the length between the abutments of the extreme spans. The retaining walls of highway bridges are frequently mere extensions of the spandrel walls, and it is deceptive to include all the area between these retaining walls as floor area, although it is frequently done. The fraction of a yard of concrete per sq. ft. should be stated. Where a large main arch is approached on each side by a number of small arches or by a concrete trestle, it is clear that the major part of the cost of the bridge may often be charged to this main arch. Hence it is not good practice to lump both the main arch and the approaches together in estimating the cost per lin. ft. or per sq. ft. of floor. Yet this is almost invariably done, as will be seen from the following records. One cost per lin. ft. or per sq. ft. should be estimated for the main span or spans, and a separate unit cost for the approach spans.

The live loads should be stated as a rule, although if the date of construction is given, together with the type of bridge, an engineer can readily ascertain what was the prevailing practice as to loading at that time. Since nearly all the bridges recorded in this article were built during the last decade, it seems unnecessary to state the loading.

The reader should note the fact that many of the concrete railway bridges have replaced steel bridges and that in nearly every case the steel bridge was approximately 20 years old when replaced. These steel bridges had in all cases become too light for the heavy locomotives and cars. So far as the past is concerned, this indicates a depreciation in steel railway bridges of about 5% per annum in America—a fact which is itself worthy of sober thought on the part of the bridge designer. We may also add in this connection that the average life of an American locomotive is not far from this same 20 years.

We shall first give the records of materials or cost, or both, of 10 highway bridges, as completely as was possible to secure them. It will be noted that for the usual spans of arches and heights of piers, reinforced concrete highway bridges have cost about \$4 per sq. ft. of floor area.

Cost of 25-ft. Arch for Highway.—A reinforced concrete highway bridge was built in 1902 in Wabash county, Ind. It is an arch with a span of 25 ft., a crown thickness of 8 ins. and a roadway 16 ft. wide. The abutments are tied together by steel rods buried in a concrete pavement below the bed of the stream, according to the Laten method. The contract price was only \$573, which is equivalent to \$23 per lin. ft., or \$1.44 per sq. ft. of floor. This price bears testimony to the economy of the design.

Cost of 45-ft. Arch for Highway.—A reinforced concrete highway bridge was built in 1902 over the River Des Peres, Forest Park, St. Louis, Mo. It is a single arch span of 45 ft., with a rise of 12 ft., and a width of 45 ft. out to out. The abutments are 8 ft. high to the spring line. The bridge cost \$12,600 (including \$2,000 for excavation and riprap), which is equivalent to \$280 per lin. ft., or \$6.20 per sq. ft. of floor.

Cost of 54-ft. Arches for Highway.—A reinforced concrete highway bridge was built in 1903 across the Kalamazoo River at Plainwell, Mich. The bridge is 414 ft. long between abutments, and has an 18 ft. carriage way and one 5-ft. sidewalk. It consists of 7 arches having a span of 54 ft. and a rise of 8 ft. Piers are only 6 ft. high to the spring line, 6 ft. wide at the spring line and rest on piles. The water was only 4 ft. deep. The arches are 1:2:4 concrete and the piers, etc., 1:3:6. The arches are reinforced with 4-in. channel steel. The materials used were:

	Cu. Yds.
Concrete in foundations.....	570
Concrete in arches.....	770
Concrete in walls.....	150
Concrete total.....	1,490

Steel, 36,000 lbs.

Earth fill, 1,944 cu. yds.

The contract price was \$19,900, which is equivalent to \$2.10 per sq. ft. of floor. There is less than 0.16 cu. yd. of concrete per sq. ft. of floor.

The detailed cost of this bridge is given in Gillette and Hill's "Concrete Construction—Methods and Cost."

Cost of 60-ft. Arches for Highway.—A reinforced concrete highway bridge was built in 1906 across the Hudson River at Sandy Hill, N. Y. The bridge is 984 ft. long between abutments and 35 ft. wide. Its deck is 24 ft. above the water surface. The river is shallow and flows over a slate rock bottom. The water is 8 ft. deep only at times of very high water. The bridge consists of 15 arches of 60 ft. span and 8½ ft. rise. The piers are 13 ft. high to the spring line. Each arch span is composed of 7 reinforced concrete arch ribs, and the ribs support a reinforced concrete slab flooring. All concrete was a 1:2:4 mixture, except the hearting of piers and the footing courses, which were 1:3:5. About 11,000 bbls. of cement were used. The outside facing of the piers and parapet walls consisted of concrete blocks. The bridge was built by day labor at a cost of \$80,000, which is but slightly more

than \$20 per lin. ft., or \$2.20 per sq. ft. of floor, which is an exceptionally low cost per sq. ft., and indicates excellent design. The bridge was designed and built by Mr. M. O. Kasson of Sandy Hill, N. Y.

Cost of 66-ft. Arches for Highway.—A reinforced concrete highway bridge was built in 1903 at Bridge St., Jacksonville, Fla., over the tracks of several railways, by the Concrete-Steel Engineering Co., under the Melan and Thatcher patents. The total length is 845 ft., consisting of 11 arches, having an average span of about 66 ft. and a rise of 7 ft., with piers about 20 ft. high and 126 piles under each pier. The width of the bridge was 58 ft. between hand rails. The contract price was \$149,900, which is equivalent to \$177 per lin. ft., or \$3 per sq. ft. of floor.

Cost of 80-ft. and 65-ft. Arches for Highway.—A reinforced concrete highway bridge of ingenious design was built in 1904 across Clifty Creek, six miles north of Greensburg, Ind., by the National Bridge Co., of Indianapolis, Daniel Luten, president. The bridge is an arch of 80 ft. span and 12 ft. rise, and has a 16 ft. roadway. The abutments are connected by steel tie rods embedded in concrete, which forms a pavement over which the creek flows. The use of these tie rods greatly reduces the mass of concrete required in the abutments. The mean depth of water was 3 ft. There were 4,500 lbs. of steel used in the ties connecting the abutments, and 4,800 lbs. in the arch and spandrel walls. The concrete amounted to only 265 cu. yds. and the contract price for this bridge complete was only \$2,895, which, so far as we know, breaks all records for low cost of a single concrete arch bridge of 80 ft. span. The cost was therefore only \$34 per lin. ft., or \$2.10 per sq. ft. of floor, or \$10 per cu. yd. There is only 0.26 cu. yd. per sq. ft. of floor. This design of Luten arch is illustrated on page 785 of Reisd's "Concrete and Reinforced Concrete Construction."

Another highway bridge of the same type is the East Washington St. bridge at Indianapolis. It has a span of 65 ft., a rise of 10 ft. and a roadway 57 ft. wide. It contains 1,100 cu. yds. concrete and the contract price was \$10,885, which is equivalent to \$167 per lin. ft., or less than \$3 per sq. ft. of floor, or \$10 per cu. yd. There is 0.3 cu. yd. of concrete per sq. ft. of floor.

Cost of 75 to 100-ft. Arches for Highway.—A reinforced concrete highway bridge was built in 1905 across the Wabash River at Peru, Ind. Its length is 700 ft., and the roadway is 30 ft. wide. The height of roadway is 30 ft. above low water. The bridge consists of 7 arch spans; one 100, two 95, two 85 and two 75 ft. The rise of the arches is 13 to 15 ft. The piers average 20 ft. high and rest on solid rock 6 to 16 ft. below low water. The bridge contains 5,000 cu. yds. of concrete, which required 6,000 bbls. of cement. The concrete was reinforced according to the Luten system. The contract price was \$36,000, which is equivalent to only \$53 per lin. ft., or \$1.80 per sq. ft. of floor, or \$7.20 per cu. yd. There is 0.24 cu. yd. of concrete per sq. ft.

This is a remarkably low cost and is indicative of good design. This contract price was lower than competitive bids for a steel

bridge of the same length having wooden flooring. This bridge was designed by the National Bridge Co. of Indianapolis, Ind., Daniel Luten, president.

Cost of 80-ft. Arch for Highway.—A concrete highway bridge was built in 1901 across San Leandro Creek, near Oakland, Cal. It is an arch (not reinforced) having a span of 81 ft., a rise of 26 ft., a crown thickness of 8 ft. and supports a macadam carriage way 41 ft. wide with 8 ft. sidewalks on each side, giving a roadway 57 ft. wide. The abutments have a thickness of 20 ft. and extend only 5 ft. below the spring line, and rest on clay. There were 90,000 ft. B. M. used in the centers and forms, or 34 ft. B. M. per cu. yd. of concrete. The spandrel walls have a length of 193 ft. each. There are 3,384 cu. yds. of concrete in the bridge, and the contract price for its construction was \$25,840, which is equivalent to \$319 per lin. ft. of span, or \$5.60 per sq. ft. of floor. There are 8.74 cu. yds. of concrete per sq. ft. of floor. The concrete was a 1 : 2 : 7 mixture, and it will be seen that the contract price for the bridge was equivalent to about \$7.70 per cu. yd. of concrete.

Cost of 85-ft. Arch for Highway.—A reinforced concrete highway bridge was built in 1903 at Seeley St., over Prospect Ave., Brooklyn. The arch has a span of 85 ft. and a rise of 8½ ft. The carriage way is 32 ft. wide and the sidewalks are each 12½ ft. wide, making a total width of roadway of 57 ft. The total length of each parapet wall is 144 ft. The abutments are 15 ft. high to the spring line. The bridge contains 1,300 cu. yds. of concrete, and 91,400 lbs. of corrugated reinforcing bars. The contract price was \$31,800, which is equivalent to \$268 per lin. ft., or \$4.53 per sq. ft. of floor, or nearly \$17 per cu. yd. There is 0.27 cu. yd. of concrete per sq. ft. of floor.

Cost of 69 to 88-ft. Arches for Highway.—A reinforced concrete highway bridge was built in 1903 across the Great Miami River on Main St., Dayton, Ohio. Its length is 588 ft. between abutments, and it has a carriageway 40 ft. wide and two 7-ft. sidewalks, making a total width of 54 ft. It consists of 7 arches having spans of 69 to 88 ft., reinforced according to the Melan system. The rise of the arches is 1-10 to 1-12 of the span. The piers are 31 ft. high to the spring line, and the base of piers is about 15 ft. below low water. The contract price was \$123,170, which is equivalent to \$210 per lin. ft., or slightly less than \$4 per sq. ft. of floor.

Cost of 80 to 110-ft. Arches for Highway.—A reinforced concrete highway bridge was built in 1904 across the Great Miami River at Third St., Dayton, Ohio. The bridge consists of 7 arches and has a total length of 710 ft. between abutments, and its width is 62 ft. between balustrades. It is of the Melan type, designed by the Concrete-Steel Engineering Co., which received a royalty of \$12,000 paid out of the contract price. The arch spans ranged from 80 ft. to 110 ft., with a ratio of span to rise averaging about 7½ to 1. The piers were 33 ft. high. The contract price was \$179,600, which is equivalent to \$253 per lin. ft., or about \$4 per sq. ft. of floor.

Cost of 100-ft. Arch for Highway.—A reinforced concrete highway bridge was built in 1907, in Rock Creek Park, Washington, D. C.,

on Ross Drive across Rock Creek. The length is 163 ft. and its width is 16 ft. It consists of a main span of 100 ft. having a 15-ft. rise, with concrete trestle approaches 30 ft. long on each side. The three hinged arch span consists of three ribs carrying, at intervals of 10 ft., light spandrel columns supporting the reinforced concrete beams and floor slabs. A steel handrail is provided on each side. An existing timber trestle was utilized for centering. The bridge was designed for a live load of 100 lbs. per sq. ft., with a concentrated load of only 6 tons on a four-wheel wagon. The bridge was built by day labor and cost \$8,000, or \$50 per lin. ft., or \$3.20 per sq. ft. of floor, including approaches.

Materials in 50-ft. and 100-ft. Arches for Highway.—A concrete highway bridge was built in 1903 over a mill pond on the Anthony Kill, near Mechanicsville, N. Y. Its length is 266 ft. between abutments, and its width is 17 ft. over all. It consists of two 100-ft. arches and one 50-ft. arch not reinforced. The rise of the 100-ft. arches is about 20 ft. The piers have a height of about 15 ft. Piles were driven to support the centers. There were 140,000 ft. B. M. in the centers and forms, which lumber was used but once. About 2,500 cu. yds. of concrete were required, or 0.56 cu. yd. per sq. ft. of floor. Therefore it took 56 ft. B. M. per cu. yd. of concrete. The centers consisted of bents supporting lagging laid parallel with the center line of the roadway.

Cost of 125-ft. Arch for Highway.—A concrete highway bridge was built in 1906 at 16th St., Washington, D. C., known as the Piney Creek bridge. Its length is 272 ft. and its width is 25 ft. It consists of a parabolic arch having a span of 35 ft. and a rise of 39 ft., resting on abutments about 12 ft. high, and a concrete viaduct approach on each side of the arch. The arch is not reinforced and is 5 ft. thick at the crown. It carries a solid spandrel wall on each side and reinforced concrete posts between the walls, which support the reinforced concrete slab roadway. The viaduct approaches are merely extensions of this spandrel construction, and have an average height of about 65 ft.

The design of this bridge is illustrated and described in Reid's "Concrete and Reinforced Concrete Construction." The cost of the bridge was \$52,231, of which \$3,000 was for engineering and \$1,500 for inspection. This is equivalent to a cost of \$200 per lin. ft., or \$8 per sq. ft. of floor area.

Cost of 135-ft. Arch for Highway.—A reinforced concrete highway bridge was built in 1907 across Cherry Creek, at Bannock St., Denver, Colo. The bridge is a one-arch span of 135 ft., consisting of 3 parabolic three hinged arch ribs. This design was adopted because the bridge crosses the creek on a skew of 34°. The rise of the arch is 13 ft., and the arch is 24 ins. thick at the crown. The arch supports a reinforced concrete slab floorway resting on reinforced concrete spandrel posts. The carriage way is 36 ft. wide, flanked by an 8-ft. sidewalk on each side, giving a total width of 52 ft. of roadway. The bridge contains 1,146 cu. yds. of 1:2:5 concrete, 166,000 lbs. of steel reinforcement and 22,000 lbs. of steel

castings. There is less than 0.38 cu. yd. per sq. ft. of floor. The contract price was \$28,325, or \$210 per lin. ft., or \$4 per sq. ft. of floor space, or \$24.60 per cu. yd. of concrete. This low cost per square foot for so long a span indicates excellent design on the part of Mr. Charles W. Comstock, M. Am. Soc. C. E. Contrast this design and cost with the design and cost of the Piney Creek bridge above given.

Cost of 180-ft. Arches for Highway.—A concrete highway bridge was finished in 1907 over Rock Creek, Washington, D. C., and is known as the Connecticut Ave. bridge. It has a total length of 1,063 ft. between abutments. The abutments are U shape, and are filled with earth, giving a total length of 1,341 ft. of bridge including abutments. The bridge consists of five concrete arches (not reinforced), each of 150-ft. span and 75-ft. rise, and two 82-ft. arches of 41-ft. rise. The 150-ft. arches support spandrel arches that carry the roadway. The roadway is about 150 ft. above the base of foundation of the center pier. The bridge is 62 ft. wide. It contains 80,000 cu. yds. of concrete, or 1.62 cu. yds. per sq. ft. of floor. The cost was \$850,000, or \$839 per lin. ft. of total length, which is equivalent to \$12.30 per sq. ft. of floor. Full detailed costs of the materials and labor required to build this bridge are given in Gillette and Hill's "Concrete Construction—Methods and Cost."

Cost of 233-ft. and 53-ft. Arches for Highway.—A concrete highway bridge was built in 1908 across the Wissahickon Creek, Philadelphia, and is known as the Walnut Lane bridge. The bridge is 585 ft. long and 80 ft. wide, having a 40-ft. roadway and two 10-ft. sidewalks. It consists of a main arch of 233 ft. span, approached on one side by three 53-ft. arches and on the other side by two 53-ft. arches. The main arch has a rise of 70 ft. and supports 8 spandrel arches. The abutments for this main arch have a height of 15 ft. and rest on rock. The concrete is not reinforced. The main arch consists of twin arch rings, side by side. The contract price for this bridge was \$253,551, which is equivalent to \$434 per lin. ft., or \$7.25 per sq. ft.

Estimated Cost of 708-ft. Arch for Highway.—Plans for a reinforced concrete highway bridge of unprecedented size have been prepared for the city of New York, and the estimated cost and amount of materials are worthy of record here. The bridge is to be known as the Hudson Memorial Bridge, and is to cross Spuyten Duyvil Creek. The bridge is to be 2,840 ft. long and 80 ft. wide. The main arch is 708-ft. span and 170-ft. rise, 70 ft. wide, 15 ft. thick at the crown and 38 ft. thick at the spring, and supports 10 spandrel arches. The approaches consist of 3 arches of 100 ft. span on one side and 4 on the other side. The bridge is to carry two decks, one for highway traffic and the other for rapid transit railway traffic. The steel in the arch ring is to be used in compression and is, strictly speaking, not a reinforcement. It averages about 1% of the volume of the arch ring. There are to be 17,000,000 lbs. of steel in the 47,000 cu. yds. of concrete in the arch ring.

The total amount of concrete is to be 75,000 cu. yds. in the main arch, including the spandrels, foundations, etc., which will contain 24,000,000 lbs. of steel. The estimated cost of the arch and approaches (2,840 ft. long) is \$2,800,000, which is equivalent to nearly \$1,340 per lin. ft., or nearly \$17 per sq. ft.

Cost of a Stone Arch Highway Bridge.—A stone highway bridge was built in 1904 across the Connecticut River at Hartford. It is 1,185 ft. long and 50 ft. wide between parapets. It consists of 8 stone arches, having spans of 68 to 119 ft., and a 100-ft. Scherer rolling lift bridge. The foundations for the piers were put down with pneumatic caissons. The toe of each caisson averaged about 30 ft. below low water level and 50 ft. below the spring of the arch. The piers and parapets are faced with granite, and the backing is concrete. There were 23,300 cu. yds. of concrete in caisson piers, 32,000 cu. yds. concrete backing, 9,300 cu. yds. granite ashlar, 10,000 cu. yds. granite voussoirs, 9,500 cu. yds. arch ring concrete and 300 cu. yds. granite parapet and posts, or a total of 84,400 cu. yds. masonry. There were 20,000 cu. yds. excavation for abutments and 37,800 cu. yds. dredging and excavation for piers. The contract price for the masonry and foundations was \$1,362,520 and the total was \$1,600,000, or \$1,330 per lin. ft., or \$17 per sq. ft. of floor.

Cost of Longest Stone Arch Bridge.—The longest stone arch bridge span in the world was begun in 1903 at Plauen, Saxony. It is a highway bridge with a roadway 36 ft. wide flanked by two sidewalks 10 ft. wide each, making a total width of 56 ft. The arch has a span of 395 ft. and a rise of 59 ft., and a crown thickness of 4.9 ft. It springs directly from ledge rock. The bridge has a total length of 492 ft. and is built throughout of stone masonry. There are about 15,000 cu. yds. of masonry in the bridge, and 548,000 ft. B. M. of timber were required for the centers and falsework. The centers rested on concrete footings. The cost of the bridge was only \$120,000, due to the low cost of labor in Saxony. This is equivalent to \$8 per cu. yd. of masonry. Hence the bridge cost \$244 per lin. ft., or \$4.35 per sq. ft. of roadway.

Estimated Cost of 50, 75 and 100-ft. Electric Railway Arches.—In estimating the cost of double track reinforced concrete bridges for interurban electric lines, Mr. George P. Carver gives the following quantities for 50, 75 and 100-ft. single span arches having a width of 28 ft. These arch spans were all designed to cross streets (not rivers) and had hollow reinforced concrete abutments.

Span. Ft.	Concrete. Cu. Yds.	Steel. Lbs.	Cost.
50	370	21,700	\$4,700
75	740	23,200	8,320
100	1,092	55,650	12,150

It will be noted that the estimated cost is \$12 to \$13 per cu. yd. of concrete, not including the cost of excavation. Prices assumed in making the estimates were as follows:

Steel, $2\frac{1}{2}$ cts. per lb.
 Placing steel, 1 ct. per lb.
 Cement, \$2 per bbl.
 Stone, \$2 per cu. yd.
 Sand, \$1 per cu. yd.
 Forms, \$1 per cu. yd.
 Mixing and placing, \$1.50 per cu. yd.
 Add for incidentals, 15%.
 Add for profit, 10%.

Materials in Concrete Railway "Trestle."—A double track reinforced concrete bridge was built in 1906 across Ames Creek for the Illinois Central Ry. It is 72 ft. long between abutments, and is 26 ft. wide out to out. It consists of 4 spans of 16 ft. each, which are such flat arch spans that they are really girders. Fourteen steel I beams (9 in.) are embedded in these spans for reinforcement. The concrete is 18 ins. thick at the crown. The piers are 3 ft. thick at the top and 10 ft. high, resting on piles. The bridge contains 725 cu. yds. of concrete, or 16 cu. yds. per lin. ft.

Materials in Concrete Railway "Trestle."—A double track concrete trestle was built in 1906 across Cave Hollow Creek for the C., B. & Q. Ry. The total length is 80 ft. between abutments. It consists of five spans of 14 ft. each resting on piers 3 ft. wide on top, 30 ft. long and 16 ft. high. The footing of each pier is 5 ft. wide and rests on 26 piles 16 ft. long. The abutments are 12 ft. high. The superstructure is composed of reinforced concrete slabs 16 ft. long, 28 ft. wide and 2 ft. 4 ins. thick, with a parapet 1 ft. high on each side. There are 24,000 lbs. of Johnson corrugated bars and 520 cu. yds. of concrete in this trestle, or 6.5 cu. yds. per lin. ft. A 1 : 2 : 4 concrete was used in the superstructure and a 1 : 3 : 6 in the piers and abutments.

Cost of Concrete Railway "Trestle."—A single track concrete trestle was built in 1905 for the Illinois Central Ry. at New Athens, Ill. Its length is 82 ft. between abutments and its width is 15 ft. over all or 12 ft. between parapet walls. It consists of 5 arch reinforced spans of 14 ft. each resting on solid piers 3 ft. thick and 19 ft. high. The arches are elliptical, having a rise of 4 ft. and a crown thickness of 16 ins. The footing of the piers is spread at the base to 8 x 19 ft., giving a load on the earth of $1\frac{1}{2}$ tons per sq. ft. The extrados of the arches is very flat and is at subgrade at the crown, so that the parapet wall, which is 18 ins. thick, has a height of only 18 ins. above the crown. A 1 : 2 : 5 concrete was used. The cost was about \$7,500, which is equivalent to \$91 per lin. ft., including a large amount of excavation for piers and abutments.

Cost of 38-ft. Arch for Railway.—A three-track reinforced concrete bridge was built in 1905 across Trim Creek, near Chicago, for the Chicago & Eastern Illinois Ry. The bridge is a reinforced concrete arch span of 38 ft. having a rise of 7 ft. and a width of 48 ft. The abutments are 16 ft. high to the spring. The arch is 26 ins. thick at the crown. The bridge contains 1,878 cu. yds. of concrete and 26,000 lbs. of Johnson corrugated bars. A similar bridge built for the same road cost \$7.66 per cu. yd., including the

reinforcing bars, at which rate this bridge would cost about \$12,000 or \$216 per lin. ft., or \$4.55 per sq. ft. There is 0.86 cu. yd. per sq. ft.

Cost of 84-ft. Arches for Railway.—A double track stone and concrete bridge was built in 1903 across Rock River, at Watertown, Wis., for the C., M. & St. P. Ry., replacing a single track iron bridge built 19 years previously. It is 280 ft. long between abutments and 30 ft. wide over all. It consists of 4 stone arch spans of 84 ft. each, with a rise of 16½ ft. and a crown thickness of 3 ft. The piers are 8 ft. wide at the spring line and 15 ft. high to the spring line, and rest on piles. The parapet walls are each 260 ft. long. The bridge contains 4,000 cu. yds. of stone and concrete masonry, and its cost was \$40,700, including removal of the old bridge, building a temporary bridge, filling and new track. This is equivalent to \$145 per lin. ft., or \$4.80 per sq. ft., or \$10.20 per cu. yd. There is 0.48 cu. yd. per sq. ft.

Cost of 88-ft. and 82-ft. Arches for Railway.—A double track reinforced concrete railway bridge was built in 1906 across the Sangamon River, near Decatur, Ill., for the Wabash Ry. Its length is 286 ft. between abutments and its width is 25 ft. between parapet walls. The bridge consists of 4 skew arches (45° skew), two of which have a clear span of 58 ft., measured perpendicular to the piers, or a span of 53 ft. measured along the center line of the railway. The other two arches each have a clear span of 48 ft. measured perpendicular to the piers, or 53 ft. along the center line. The rise of the arches is 20 ft. and the piers have a height of 26 ft. The three piers are in water about 5 ft. deep. At each end of the bridge is an abutment with side retaining walls 126 ft. long. This bridge was reinforced with corrugated bars. It replaced a steel bridge built 21 years previously. The following quantities were involved in the construction:

Earth excavation, cu. yds.....	2,226
Piling, lin. ft.....	34,775
Foundation slabs for piers, concrete, cu. yds.....	1,200
Piers proper, with skewbacks, concrete, cu. yds.....	2,370
Arch rings, concrete, cu. yds.....	1,310
Spandrel walls of arches, concrete, cu. yds.....	2,190
Foundations for abutments, concrete, cu. yds.....	1,560
Abutments above foundations, including slabs and intermediate walls, together with spandrel walls, concrete, cu. yds.....	5,920
Retaining walls, concrete, cu. yds.....	540
Reinforcing bars, lbs.....	430,000

The cost was \$124,000, which is equivalent to \$331 per lin. ft., or \$12.80 per sq. ft. of roadway. The total amount of concrete is 16,170 cu. yds., so that the cost of the bridge was equivalent to \$7.65 per cu. yd. There are 1.68 cu. yds. per sq. ft.

Materials in 74-ft. Arch for Railway.—A four-track concrete bridge, 160 ft. long, was built in 1904 across the Ashtabula River, Ohio, for the Lake Shore Ry. It comprised two 74-ft. concrete arches having a rise of 27 ft., resting on piers and abutments only 6 ft. high. The arches were 7 ft. thick at the crown and 21 ft. at the spring, and were not reinforced. An earth fill 30 ft. deep over

the crown was placed upon the arches, making it necessary to have the barrels of the arches 145 ft. long. There were 17,500 cu. yds. of concrete and 50,000 cu. yds. of earth fill. This bridge is a good example of poor design, for, at \$8 per cu. yd. for concrete and 15 cts. per cu. yd. for fill, its cost would be \$147,500, or more than \$900 per lin. ft., or about \$12 per sq. ft. of roadway. A narrow bridge with spandrel piers supporting the roadway could have been built at far less cost. It will be noted that there were about 2.3 cu. yds. of concrete in this bridge per sq. ft. of roadway.

Materials in 75-ft. Arch for Railway.—A reinforced concrete railway bridge was built in 1903 over Big Rock Creek, 51 miles west of Chicago, on the line of the C., B. & Q., replacing a steel bridge built 22 years previously. The span is 75 ft. The bench walls are 12 ft. high, and the rise of the arch is 28 ft. It is a three center arch 3 ft. thick at the crown and the barrel length is 44 ft. There is no appreciable fill over the crown. The arch is designed for a loading of 1,000 lbs. per sq. ft. The wing walls are each 55 ft. long, and 10½ ft. thick at the bottom. The abutments of the arch are 25 ft. wide at the base. Abutments and wing walls rest on piles. Corrugated steel bars are used for reinforcement. There are 6,588 ft. of ¾-in. bars and 34,046 ft. of ½-in. bars in the bridge. The arch ring is 1 : 3 : 4 concrete and contains 770 cu. yds. The rest of the concrete is 1 : 3 : 6. The total concrete in the structure is 3,350 cu. yds., or nearly 45 cu. yds. per lin. ft., or 1 cu. yd. per sq. ft.

Materials in 80-ft. and 100-ft. Arches for Railway.—A double track concrete bridge was built in 1906 across the Vermillion River, for the Cleveland, Cincinnati, Chicago & St. Louis Ry. It consists of two 80-ft. arches and one 100-ft. arch between them. The piers of the 100-ft. arch are 20 ft. high to the spring line, and the arch has a rise of 40 ft. These main arches support a series of small spandrel arches having spans of 8 ft., resting on piers 2 ft. thick. The crown thickness of the 100-ft. arch is 4 ft. The base of rail is 20 ft. above the crown and 30 ft. above the foundations of the center piers. The bridge has a total length of 220 ft. between abutments, a width of 29 ft. between parapets, and contains 12,000 cu. yds. concrete, or nearly 41 cu. yds. per lin. ft., or 1.41 cu. yds. per sq. ft. The bridge is designed as a plain concrete bridge, although steel reinforcement is used as a precautionary measure. There were 250,000 lbs. of Johnson corrugated bars used. The bridge required 500,000 ft. B. M. for centers and forms, which is equivalent to 42 ft. B. M. per cu. yd.

Materials in 100-ft. Arches for Railway.—A single track concrete bridge was built in 1906 across the Cumberland River for the Kentucky & Tennessee Ry. It is 500 ft. long between abutments, consisting of 5 spans of 100 ft. c. to c. of piers, and the width is 16 ft. between parapet walls. The bridge is on a 30° skew. The arches have a rise of 18 ft. and a crown thickness of 3 ft. 7 ins. The piers are 40 ft. high. There are 6,470 cu. yds. of concrete and 240,000 lbs. of twisted steel reinforcement in this bridge. This is equivalent to nearly 13 cu. yds. per lin. ft. of bridge, or about 0.8 cu. yd. per sq. ft. of roadway.

Cost of 140-ft. Arches for Railway.—A double track concrete railway bridge was built in 1902 across the Big Muddy River for the Illinois Central Ry., to take the place of a single track steel bridge built 13 years previously, which was getting too light for the traffic. The bridge is 463 ft. long between abutments and 32 ft. wide, or 26 ft. between parapet walls. It consists of three elliptical arches (not reinforced), each having a span of 140 ft., a rise of 20 ft. and a crown thickness of 7 ft. These main arches supported spandrel arches of 13 ft. span reinforced with steel skeletons made principally of rails. The piers are about 22 ft. high to the spring line and are built around and over the old single track bridge piers.

The total cost was \$125,000, which is equivalent to \$270 per lin. ft., or \$10 per sq. ft. of roadway. There were 12,800 cu. yds. of concrete, or 26 cu. yds. per lin. ft., or 1 cu. yd. per sq. ft. of roadway; 5,000 cu. yds. of excavation, which cost 76 cts. per cu. yd.; 400,000 ft. B. M. in cofferdams, centers and forms, and 300,000 lbs. steel reinforcement. The labor cost of handling, punching and erecting the steel was 0.61 ct. per lb.

Materials in 140-ft. Stone Arch for Railway.—A double track stone bridge was built in 1898 across the Connecticut River, at Bellows Falls, Vt., for the Fitchburg railroad. It consists of two stone arch spans of 140 ft. each, having a rise of 20 ft. The width over all is 27 ft. The arch sheeting is 4 ft. thick. The bridge is peculiar in that it has no masonry abutments or pier, the arches springing directly from ledge rock on each bank and from a rock island in the center of the stream. This natural pier in the middle of the river is 32 ft. thick along the spring line, thus giving a total length of bridge of 312 ft. between the natural abutments. There were 232,000 ft. B. M. required for the centers, or 56 ft. B. M. per cu. yd. of masonry in the bridge. The masonry was as follows:

	Cu. Yds.
Ring stones and skewbacks.....	1,263
Coping	286
Rubble	2,467
Concrete in foundations.....	180
Total	4,196

This is equivalent to 13½ cu. yds. per lin. ft.

Price of a Concrete Arch Highway Bridge.—Mr. William B. Barber gives the following data: This highway bridge crosses San Leandro Creek, Cal. It has a macadam roadway 41 ft. wide, and two 8-ft. cement walks. The span is 81½ ft., the rise is 36 ft., and the thickness is 3 ft. The footings have at the crown a width of 30 ft. on each side and extend 5 ft. below the bed of the creek, resting upon a bed of clay without any pile supports. There were 30,000 ft. B. M. of lumber in the centers. The concrete was a 1:2:7 of broken stone. The bridge contains 3,389 cu. yds. and was built at a contract price of \$25,840 by the H. B. & A. L. Stone Co., of Oakland, Cal.

Materials in a Concrete Highway Bridge.—A concrete arch highway bridge was built across the River Eyach, near Insam, Germany, in 1886. It is a three-hinge arch, the hinges being of granite with intermediate sheets of 3/16 in. lead. The span is 98 ft.; the rise is 9.8 ft.; the thickness at the crown is 1.48 ft.; at the haunches, 2.63 ft.; at the spring joint, 1.64 ft. The carriageway is only 8.2 ft. wide, and the two sidewalks are each 2.46 ft.; total, 13.12 ft. The arch spreads in width to 11.48 ft. at the spring lines. The roadway rests on the arch at the center, and is supported by four spandrel arches resting on three piers at each end. Each abutment rests on 41 batter piles, 13 ft. long. The bridge was designed to carry 74 lbs. per sq. ft. and a 16½ ton steam roller, with compressure stress not exceeding 480 lbs. per sq. in., and tensile stress not exceeding 57 lbs. There are 408 cu. yds. of concrete in the bridge, including foundations, built for \$3.30 per cu. yd. for foundation and \$3.34 for arch. Contract price was \$2,930, including excavation and piles.

Dimensions and Cost of Forty-five Concrete Arch Bridges.—In *Engineering-Contracting*, Mar. 17, 1909, the following table of costs, by Mr. E. P. Goodrich, is printed.

Table XX gives some of the dimensions and costs of a number of arches. In the case of single arch spans, the cost per square foot is computed from face to face of abutments and out to out of railings.

Cost of Concrete Bridges.—In a table covering eighteen concrete arch bridges recently built in Philadelphia the contract price spread upon the span area—the clear span by the width—varies from \$2.11 to \$9.74 per sq. ft. and it varies from \$1.73 to \$7.39 per sq. ft. of area occupied by the ground plan to ends of wings, the latter extremes being not on the same bridges as the other two. The average of the lot was \$6.25 per sq. ft. of span area and \$3.50 per sq. ft. over all, most of them being single span bridges with long wings, and all being highway bridges designed to carry loads of 40 tons on two axles 20 ft. apart. All have ornamental concrete balustrades and washed granolithic surfaces and paved decks, with electrical conduits and manholes, and water pipe and sewer well-holes and some have pretty deep foundations. If the whole contract price be set against the yardage of the concrete in the structure the unit costs vary from \$8.50 to \$11.25 per cu. yd., averaging \$9.75. Mr. Henry E. Quimby, Engineer of Bridges, Philadelphia, Pa., is authority for these figures.

Concrete Arch Bridge, S. P., L. A. & S. L. R. R.—Mr. A. C. Ostrom gives the following facts about an eight-arch bridge crossing the Santa Ana River on the San Pedro, Los Angeles & Salt Lake R. R. The bridge is 984 ft. long, 17 ft. wide, 55 ft. high (averaged), and contains 14,080 cu. yds. of concrete without any steel reinforcement. Each arch has a radius of 43½ ft., a rise of 37 ft., and a thickness of 42 ins. at the crown. The arch ring projects 6 ins. beyond the face of the spandrel walls. The piers have a footing 16 X 28 ft. resting on granite, and narrow by steps

TABLE XX.—DIMENSIONS AND COSTS OF CONCRETE ARCH BRIDGES.

Place.	Over.	Total Length Bridge.	Arch Spans.	Width.	Rise of Arch.	Total Cost.	Cost per sq. ft.	Date Erected.

to 9 × 21. They are penetrated vertically by two walls 2½ × 5 ft., thus saving concrete and providing drainage by weep holes below and horizontal tunnels at the top of the arch haunch. There are two sets of spandrel walls connected by cross walls, covered by a 18-in. concrete floor which sustains the 3½ ft. of ballast. Cement and gravel in the ratio 1 to 11 were used for the foundations and spandrel walls. The arch rings were made of 1:2:4½ stone concrete. The gravel was washed by means of a sluice passing through a box where the coarse gravel and clean sand settled. Three Ransome mixers were operated by a 25-hp. engine. The arch centers were supported on four bents of four piles per bent driven to bed rock. These were capped by 12 × 12-in. caps. The thrust from the segments was conveyed by radial 8 × 8-in. struts to horizontal chords which were upheld by wedges placed on 12 × 12-in. stringers that rested upon the caps.

Cost of a Reinforced Concrete Arch Highway Bridge.—Mr. P. A. Courtright gives the following on the cost of mixing and placing concrete in a concrete bridge having 7 arches, each of 54 ft. span and 8 ft. rise, at Plainwell, Mich., in 1903, as follows:

	Total per day.	Total per cu. yd.
12 men, at \$1.80.....	\$23.40	\$0.78
Engine and mixer.....	5.00	0.17
1 team	3.00	0.10
1 foreman	3.00	0.10
Total labor for 30 cu. yds.....	\$34.40	\$1.15
0.9 cu. yd. gravel, at \$0.50.....		\$0.45
0.65 bbl. cement, at \$2.00.....		1.29
Total, per cu. yd.....		\$2.99

The concrete yardage was as follows:

5.70 cu. yds. of 1:8 gravel concrete in foundations.

770 cu. yds. of 1:6 gravel concrete in arches.

150 cu. yds. of 1:6 gravel concrete in walls.

One sack of cement was considered to be 1 cu. ft. The bridge had an 18-ft. roadway and a 5-ft. side wall, a total length of 446 ft., and the estimate of its cost at contract prices was:

1,490 cu. yds. concrete, at \$7.00.....	\$10,430
1,200 cu. yds. earth fill, at \$0.30.....	360
25,000 lbs. of steel, at \$0.05.....	1,250
2,800 ft. of piles in foundations, at \$0.20.....	560
2,230 sq. ft. of cement walk, at \$0.10.....	223
Total	\$12,773
Excavating, pumping, coffer dams, and centers, \$791 per arch	5,527
Grand total.....	\$18,300

The method of making the concrete was as follows: The gravel, which had 33% voids, and contained sufficient sand, was shoveled into a 1 cu. yd. wagon at the pit, and hauled to a platform at the intake of a McKelvey continuous mixer. Half the cement required for a batch was spread over the load of gravel before dumping the load through the bottom of the wagon; then the rest of the cement was added after dumping. One man shoveled the material over to another man who shoveled it into the mixer. After the material had passed one-third the length of the mixer, water was turned in. The mixer delivered the concrete into wheelbarrows from which it was dumped to place and spread in 3-in. layers. Two men were employed tamping to 1 man shoveling the concrete. The gravel for the arches and walls was screened through a 2-in. mesh screen placed on the wagon while loading at the pit. Regarding the product of the mixer, Mr. Courtright says: "A more complete blending of materials would be difficult to produce." This statement is noteworthy in view of the common prejudice against continuous mixers.

Centers.—The heels were supported on the benches constructed upon each pier and abutment foundation. Each center was supported to the panel joints by twelve temporary piles. These were driven in advance of the foundation work, sawed off, capped with timbers, and used as a working platform.

The centers themselves were made of Georgia pine plank. Each rib section was built up with three planks, two 2 × 12 inch for outside, and one 10 × 2-inch between. These were securely nailed and bolted together, the panels being joined by bolting on two pieces of 2 × 4-inch oak.

The top chord was made of one plank, cut in sections, and rounded to fit the intrados of the arch. The panel joints were supported by 8 × 12-inch timbers, carried on posts resting on 8 × 12-inch timber caps on piles.

Wedges for lowering the centers were used at all bearing points.

Centers were covered with 2 × 12-inch planed pine lagging and made a very rigid and smooth surface for concrete. The minimum of time allowed for the removal of centers after the completion of an arch was 28 days.

The appearance of the arch rings, showing the same divided as by joints between stones, was produced by nailing half round strips on the form, and gives a good structural effect to the work. The entire structure was built in the forms with the single exception of the fourteen keystones, which, owing to their peculiar design, were cast separate, and set in the form.

Piling.—Each abutment foundation has 31 piles, the piers having 23 each. Piles were oak, elm, beech and hickory, not less than 12 ins., nor more than 16 ins. at the head. They cost, delivered on the ground and sharpened ready for driving, 15 cents per lineal foot. The average number driven per day was 8½.

The character of the soil rendered driving very difficult; a penetration of 2 or 3 ins. when starting a pile was the exception rather than the rule.

Cost of driving—

Engine and driver, per day.....	\$ 5.00
Engineer	2.50
Fireman	1.80
Four driver men, at \$1.80.....	7.20
Total	\$16.50

Conditions for construction were very favorable. The water varied in depth from 3 to 5 ft., with a current of from two to three miles per hour. Under the silt and sand which formed the river bed, gravel was found to depth of about 2 ft.; below this, quicksand, filled with stones of varying sizes, was encountered.

For foundations, piles were driven to an approximate depth of 10 ft. below the bed of the stream. Cofferdams were built, the water pumped out, and the excavation carried down until 1 ft. of gravel was left above the quicksand. The piles were sawed off 1½ ft. above the bottom of the excavation, and the concrete carried up to the spring line of the arches.

Cost of Three Reinforced Concrete Arch Bridges, L. E. & M. R. Ry.—Mr. Samuel Rockwell gives the following as to the size and cost of three reinforced concrete railway arch bridges. The bridge arches had a span of 30 ft., a rise of 9 ft., a crown thickness of 33 ins., a thickness at the spring of 6½ ft., and a barrel length of 40, 60 and 160 ft., respectively. The abutments were 8 ft. high and 14 ft. wide at the base. Johnson corrugated steel bars were used for reinforcement. The concrete was 1 sand, 3 gravel and sand (50% each) and 6 broken stone laid wet. In all there were 4,833 cu. yds., including wing walls and parapets. The work was done by company forces at Elkhart, Ind., in 1903. It will be noted that the sand and stone were unusually low in cost.

	Total cost.	Cost per cu. yd.
Cement	\$ 5,360	\$1.84
Stone	1,789	0.36
Sand and gravel (obtained from foundations)	240	0.06
Drain tile.....	103	0.03
Steel rods.....	3,038	0.63

Engineering and watching.....	508	0.11
Arch centers and forms.....	3,529	0.73
Sheet piling and boxing.....	1,006	0.21
Excavating and pumping.....	1,820	0.38
Machinery, pipe, fittings, etc.....	416	0.09
Temporary buildings, trestles, etc.....	752	0.15
Total for 4,833 cu. yds.....	\$29,942	\$6.19

Cost of Small Reinforced Concrete Highway Bridges.*—Reinforced concrete highway bridge construction is being widely advocated by

**Engineering-Contracting*, Dec. 2, 1903.

the Illinois Highway Commissioner, Mr. A. N. Johnson, State Engineer. To encourage the building of such bridges, he has worked out two general standard designs. He recommends reinforced concrete for all spans under 50 ft. in length. It has found that for

Fig. 16.

Fig. 17.

spans under 40 or 50 ft., reinforced concrete can be used at very reasonable cost and that for longer spans a reinforced concrete floor does not add an excessive amount to the cost of the bridge.

Spans Under 18 Ft.—For spans under 18 ft. in the clear a plain reinforced concrete slab is used for the floor, the principal rein-

forcement running from abutment to abutment. Reinforced concrete side rails are used for this class of bridge and are considered preferable to pipe or angle rails because of their strength and durability. Figures 16, 17 and 18 show the plans for one of these bridges. In constructing these bridges Mr. Johnson says:

"Where a number of slab bridges under 20 ft. in span are built the same season, it may prove cheaper to use I-beams to support the slab until the concrete has set than to use mud sills and timber posts. If this is done the abutments are carried up as usual to the height of the under side of the floor, pockets being left for the I-beams; these pockets being about 8 ins. wide and deep enough so that when opposing wedges are placed under the ends of the I-beams the top flanges of the I-beams will be 2 ins. below the

Fig. 18.

level of the bottom of the slab. Two-in. planking is used to support the slab. When the concrete in the slab and rails has hardened sufficiently the wedges are removed and the floor forms drop down; the planks are drawn out at the sides and likewise the I-beams through the pockets in one of the abutments. The pockets are then filled with concrete. The I-beams and planks may be used repeatedly."

Spans From 18 to 42 Ft.—For spans ranging in length from 18 to 42 ft. the concrete rails have been designed as girders to carry the load to the abutments. The floor in this case is a reinforced concrete slab, the main reinforcement running from girder to girder. The floor is suspended to the girders by bending every third floor bar up into the girders. This type might well be classed as a reinforced concrete through girder bridge. This has proved to be a very economical design. The forms are very simple and much

of the lumber remains uncut. The bending moment in the floor slab is independent of the length of the span, and consequently the amount of concrete and steel in the floor slab, for a given width of roadway, remains constant per foot of bridge. The rails or girders for bridges 18 to 30 ft. in span contain but little more concrete than would ordinarily be necessary for appearance and economical placing in the rail forms. For spans over 30 ft., and particularly for wide roadways, the girders become heavier, and it has been found necessary to design the girders with a heavy coping, giving the girders a T-beam section. A number of girder bridges of this character have already been built and the plans drawn for several which will be built the coming season.

The dimensions, quantities and costs for a number of the bridges built on these plans are given in Table XXI.

Cost of a Reinforced Concrete Highway Bridge.—The bridge had a clear span of 30 ft. and an 80-ft. roadway. The arch ring was 8 ins. thick at the crown and 12 ins. thick at skewbacks, with a rise of approximately 6 ft. It rested on 12-in. abutment walls, with center posts and 21-in. footing slabs. The spandrel walls were 12 ins. thick and reached well beyond the abutment walls on each side, the free ends having inside counterforts. The height of the abutment walls from skewback to water level was 13 ft. These walls were continued beyond the faces of the spandrel walls by wing walls, which held the slopes of the deep fill from the channel. This fill reached to a height of 4 ft. above the crown of the arches. All walls were founded on piles. There were 872 cu. yds. of concrete in the structure. The general design was made by City Engineer M. P. Blair, St. Boniface, Manitoba, where the bridge was built and the reinforcement was designed and supplied by Clarence W. Noble, Winnipeg, Manitoba. The reinforcement was high carbon square twisted steel bars. The work was done by day labor by the city engineer and cost as follows:

<i>Foundations—</i>		Total Cost.
5,336 cu. yds. excavation, at 38.2 cts.....		\$2,034.63
6,060 lin. ft. piling, at 14.7 cts.....		893.85

The work was carried on under considerable difficulty. The excavation was interrupted by frequent rains, and the banks slipped, causing the handling of considerable additional material. The work of driving piles was also frequently interrupted by rain, and as a consequence the extra work of placing concrete did not start until late in the fall, and had to be prosecuted by two shifts, working day and night, Sunday included, until it was finished. The conditions are reflected in the high unit cost of excavation. The cost of placing reinforcing bars is about typical, while the cost of placing concrete at \$1.61 per yard is abnormal, owing to the fact that in this item is charged considerable general labor, which could not be otherwise apportioned.

The specifications originally contemplated the use of crushed limestone, but there was submitted to the engineer samples of very good gravel at a price of \$1 per cu. yd. This gravel was clean, and contained enough sand to fill the voids without additional material; in fact, some of it contained slightly too much sand. The cost of sifting out the coarse material and again sifting out the fine material, and then mixing the two together in the proper proportions was found to be 32 cts. per cu. yd. This was used for all arch concrete, but for abutments the mix of the gravel as delivered was deemed satisfactory, as it did not vary greatly from the proper proportions. The footings were made of crusher rock dust and limestone, which had been owned by the city for several years. This material is considered as costing the same as gravel.

Cost of Mixing and Placing Concrete for an Arch Bridge.—A natural mixture of sand and gravel was brought in on trucks *AA* by electric railway and discharged through gratings into a storage bin, Fig. 19. Five parallel charging car tracks *BB* ran under this storage bin. The charging cars *C* were 16 cu. ft. capacity, just one batch for the mixer. A car was first loaded with gravel under one of the hoppers, then moved back under the cement chute to receive the cement, and then moved forward onto the truck *F* which traveled on the transverse track passing the mixer. The mixer discharged into a hoist bucket *I* which automatically discharged its load into the hoppers *JJ* whence the concrete was chuted into wheelbarrows, two wheeled carts or dump cars and taken out on

Fig. 19 —Concrete Mixing Plant.

trestles to the work. The gang charging and mixing and placing the concrete was as follows:

Duty.	No. men.
Charging cars.....	3
Cement	1
Operating mixer.....	3
At hopper in tower.....	1
Wheeling concrete.....	3 to 5
Placing and spading concrete.....	3
Hoist engineer.....	1
Fireman (mixer and pump).....	1
Total	15 to 17

This gang placed on an average 150 cu. yds. of concrete per day, or about 10 cu. yds. per man. With wages averaging \$2 per man per day this would give a labor cost of 20 cts. per cu. yd. for mixing and placing, not including superintendence.

Cost of a Reinforced Concrete Arch Bridge.—In *Engineering-Contracting*, July 22, 1908, Mr. John Harms gives the following data: The bridge has a roadway 30 ft. wide in the clear, and two sidewalks 8 ft. wide each. The length of the bridge is 306 ft.

Fig. 20.

Fig. 20.—Concrete Arch Bridge.

divided as follows: 20 ft. for each abutment, 31 ft. for each outer arch, 88 ft. for center arch and 8 ft. for each pier. The reinforcement used in the arches is 1 in. twisted steel, 3 ft. c. to c. in two rows, $1\frac{1}{2}$ ins. from extrados and intrados and tied to $\frac{1}{2}$ in. square transverse rods every 5 ft. The reinforcement of the overhanging sidewalks is of expanded metal No. 4 gage 6 in. mesh, which is turned down at the outer edge for about 4 ins. and fastened to a $\frac{1}{4}$ in. square rod, and on the inner edge is hooked to a 1 in. twisted rod which is anchored with $\frac{1}{2}$ in. twisted rods to the bottom reinforcing rods of the arch, as shown by Figs. 20 and 21.

The thickness of concrete of the arches is 40 ins. for the outer arches at haunches, 30 ins. at a distance of 16.5 ft. from haunches and 21 ins. at the crown. For center of the arch the thickness is 42 ins. at haunches, 30 ins. at distances of 16.5 ft. from haunches and 22 ins. at the crown.

The piers are of monolithic construction. The upstream and downstream ends form a sharp point, reinforced with blocks of brown stone, cut to the proper angle to break the ice. Piers and

abutments were built up to an elevation of 9.5 ft. above low water mark. Since the bed of the river is soft mud, each of the piers was built on a foundation of 60 piles driven 3 ft. c. to c. and cut off at an elevation of 2 ft. below M. L. W.

On account of the kind of soil it was necessary to drive piles for the falsework, and this was begun at the same time as the jetting for the sheetpiling of the abutment. The piles for falsework consisted of nine rows of five piles each for outer arches, and ten rows for center arch. After piles for first arch were driven, pile driving for pier No. 1 was started. This being finished, jetting of sheetpiling for the pier was started. Up to this time the

Fig. 21.—Cross-Section of Bridge.

water in the river was as low as 2 ft., making it impossible to float any craft, and so cribwork had been used for handling the pile driver. Heavy rainfalls raised the water to 10 ft. and caused at times such strong currents that the work had to be stopped. This brought the cost of labor much higher than it would have been under ordinary circumstances. The cost of jetting the sheetpiling on the pier is given further on. After the sheetpiling was all driven and properly shored for heavy water pressure a centrifugal pump was installed, driven by the pile driver engine, and the enclosure was kept dry until concrete was in place. Excavation was extended to 3 ft. below low water mark and the piles cut off 2 ft. below the same level, so as to enclose them in about 12 in. of concrete. The whole space was then filled in with concrete up to M. L. W., and on this foundation the forms for the pier were built.

At this time excavation for abutment No. 1 was finished and a Toppel industrial railway had been laid. This railway was laid

on a temporary trestle across the river and was provided with switches to reach abutments and piers.

Sheetpiling of the abutments served as forms up to about 4 ft. below the spring line. Above this point, forms of 2 in. spruce were built. The designing of an 18-in. crown molding on all piers and abutments at the height of the spring line of arches made the forms rather expensive. The concrete in the abutment was finished in broken layers on the arch side to give a good bond between arch and abutment. While the concreting on abutments and piers was being done, the building of falsework for the first arch had proceeded.

The construction of this falsework was as follows: Piles were cut off at a height of 3 ft. below the bottom line of the concrete

Fig. 22.—Falsework and Forms.

arch. On these piles were placed, transverse to the arch, two 6 x 12-in. caps, spiked to piles well spliced together at joint in center, and overhanging about 6 ft. at outside. An upper cap was made of two 6 x 12-in. timbers. Between the two caps oak wedges were placed about every 5 ft. On top of the upper caps were placed 3 x 12-in. floor beams 2 ft. 8 in. c. to c., cut on top to proper line of arch. A 2-in. spruce floor was nailed to these floor beams (see Fig. 22).

It may be well to remark here that the centers were laid out full size on a large platform, and patterns were made of 1-in. pine boards for all floor beams and side forms of arches. The cutting of all the floor beams was done by a 12-in. circular saw, which was run by a belt connected to the hoisting engine which pulled the cars up the incline to the mixing platform.

The different radii of the arches made the curves of the floor beams vary to such an extent that the amount of framing of center done per day varied a great deal. The side forms of arches were made of 2-in. spruce and built in sections of 7 ft. In this way the

placing of forms was done quickly and cheaply. The specifications stated that the concreting of the arches should be done in ribs of such a width that one complete rib of the arch could be finished in a day. Three more forms similar to the outside forms were made and so placed as to divide the arch into five equal ribs.

Since it is important to have reinforcement at the proper distance from intrados and extrados, little cement blocks of $1\frac{1}{2}$ -in. thickness were made to hold the bars at the proper distance from the bottom. The advantage of using concrete blocks instead of wooden blocks, as is usually done, is easily understood. The blocks, being of concrete, stay in place, require no pointing up afterwards, and the cost of making them is about $\frac{1}{2}$ ct. each.

After placing, upper longitudinal bars, sticks were used to hold these in place, but the writer proposes on future jobs to make concrete blocks as shown in Fig. 23. The cost of such a block the writer believes would be small, while its efficiency would be such as to make it economical.

Fig. 23.

As shown in plan, Fig. 21, the reinforcement of spandrel walls and overhung sidewalk was anchored to the lower rods or arch, and the 1-in. rod was suspended at the proper height on wooden brackets nailed to the outside of the arch forms. From this bar, $\frac{1}{4}$ -in. twisted rods were run to the lower rods, every 18 ins., being hooked on both rods by turning the ends.

Pile driving and sheetpiling had been going on, and when high water caused this work to be stopped, concreting of abutment No. 2 was done.

The industrial railway proved of great value during all this time for handling materials in an economical way.

It may be well to mention the method used for handling the materials. The stone and sand had to be stored on building lots about 250 ft. away from the proposed bridge. A platform 14×16 ft. was built about 60 ft. from this place at an elevation of 16 ft. Under this platform was placed a Smith mixer, blocked up on timbers, high enough to allow of dumping into the Koppel side

Dumping cars. A timber trestle was built extending from stone and sand pile to the top of the platform and an industrial railway laid on this. Cars were pulled up the incline by a hoisting engine stationed back of the mixer. See Fig. 24. A switch was placed at the bottom of the incline, making it possible to work two cars. Those cars were marked to give the proper quantities of sand and stone for a $\frac{1}{2}$ batch proportioned 1:3:6. Atlas cement was used and as it was taken from the storage house it was put on the cars in bags enough for every batch, and opened and emptied at the platform. Each car furnished also all the materials required, and in this way an output was obtained of 35 to 40 batches per hour. Starting from the mixer was the other industrial railway previously mentioned. The elevation of track at the mixer was 14 ft. 3 ins. above M. L. W. The tracks had a down grade of about 4 ft. to a length of 150 ft.

Fig. 24.

This brought the rails at the proper height for dumping concrete into piers and abutments, and at the same time, gave the cars enough momentum to require but little pushing.

After finishing the piers and abutments to the spring line, the track was removed and laid to the arches. Heavy timber was placed across the arch forms on which were laid longitudinal timber to carry tracks. At the crown of the first arch the track was elevated and cars were pulled up this grade by the hoisting engine, from which point they proceeded by their own momentum. On the crowns of the first and center arches, switches were put in, and by this arrangement three cars were handled so rapidly that at no time did the mixer have to stop on account of there not being cars available.

The plant proved sufficient to do the work in remarkably short time. The time from beginning concreting of first arch until the third was finished, including the erection of all falsework and

forms for the last two arches, was only 29 days. All the concrete was placed in 15 days, working not longer than 7 hours a day. If four ribs instead of five had been made in each arch, the results would have been even better, but this would have meant taking a great risk, on account of doubtful weather at this season of the year and also in case of any breakdown of machinery.

The building of falsework for the spandrel wall and overhanging sidewalk proved difficult and was by far the most expensive of all form work.

This falsework was constructed by resting one side on posts placed on the caps of the falsework of the arches, while the other side was held up by posts placed at a slight angle and rammed in the mud of the river bottom. These posts and the caps on them were 8 x 10-in. timbers. On these caps 3 x 12-in. floor beams were placed 3 ft. c. to c., being covered with 2-in. spruce flooring, cut into 4-in. strips, the edges being tapered to make tight joints. The whole falsework was well braced. At all corners of forms, molding was nailed to the forms to round off the corners of the concrete. Panel effects in the concrete were also made by nailing battens to the forms. These pieces were generally planed.

Each arch had expansion joints of $\frac{3}{4}$ in. at both ends and also at a distance of 24 ft. 3 ins. from both ends. Each expansion joint was made up of $\frac{1}{4}$ -in. corrugated paper covered on both sides with 3-ply tar paper.

Balusters.—The balusters for the railway were all made on the job, there being 350 required, and for this purpose eight forms were made. These were made in four parts each and were held together with bolts so that removing the form was easily done.

The base of these balusters was 8 x 8 ins., the height being 2 ft. As previously stated, eight forms were made for this work. The forms were made on the job. The entire labor cost of making the balusters was:

Carving white wood blocks, 1 man, 12 days, at \$2..	\$ 24.00
Making 8 forms, 1 man, 12 days, at \$2.75.....	23.00
Making and finishing balusters, 1 man, 25 days, at \$2.75	\$6.25
Total	\$165.25

A man made 10 balusters per day. The cost for forms was 19.7 cts. per baluster, and for making and finishing, each 27.5 cts., giving a total cost for labor of 47.2 cts.

Sheet Piles.—In jetting down the sheet piles, which were 2 x 8 ins. x 20 ft. long on an average, 100 pieces were put in place per day, or 1 piece every 6 minutes. This does not include moving machine from one pier to another, but does include moves while working on a single pier. The labor cost was:

1 Foreman	\$ 5.00
1 Engineman	3.50
2 Hosemen, at \$3.50.....	7.00
2 Men preparing piles, at \$2.50.....	5.00
7 Helpers, at \$1.75.....	12.25
Total	\$32.75

There being 2,000 lin. ft. of piling or 3,666 ft. B. M. gives a unit cost of 1 $\frac{6}{10}$ cts. per lin. ft. and \$12.25 per M. ft. B. M. for the labor.

Forms.—The labor costs for forms for the spandrel wall and overhanging sidewalk on the two sides of an arch were:

Foreman carpenter, at \$6.....	\$ 20.00
Building falsework:	
2 Carpenters, at \$3.50.....	28.00
3 Men, at \$2.....	24.00
Building forms:	
2 Carpenters, at \$3.50.....	28.00
6 Carpenters, at \$3.....	75.00
2 Carpenters, at \$2.75.....	22.00
2 Helpers, at \$2.....	26.00
Total	\$223.00

There was about 12,000 ft. B. M. of lumber used in these forms, thus giving a cost of framing and erecting per M. ft. B. M. of \$18.60. With 180 cu. yds. of concrete put in these forms the cost per cu. yd. was \$1.24 for the labor on the forms.

The cost of erecting the forms for the arch, exclusive of the piling, was:

Foreman carpenter, 4 days, at \$5.....	\$ 30.00
Falsework, 3,500 ft. B. M., erecting crew:	
2 Men, at \$3.50.....	7.00
2 Men, at \$2.50.....	5.00
2 Men, at \$2.00.....	4.00
2 Men, at \$1.75.....	3.50
Total, 4 days, at.....	\$19.50
78.00	
Floor beams, 5,960 ft. B. M., carpenter crew:	
2 Men, at \$3.50.....	7.00
4 Men, at \$3.00.....	12.00
3 Men, at \$2.75.....	8.25
1 Man, at \$2.00.....	2.00
2 Men, at \$1.75.....	3.50
Total, 2 days, at.....	\$32.75
65.50	
Erecting crews, 2 days, at \$19.50.....	39.00
Forms, bottom and sides, 11,000 ft. B. M., carpenter crew:	
Framing forms, 2 days, at \$32.75.....	98.25
Setting forms, 2 days, at \$32.75.....	65.50
1 man making patterns, 3 days, at \$3.50.....	10.50
Total	\$386.75

There was 25,400 ft. B. M. of lumber in the falsework and forms exclusive of the piles, which makes a cost per M. ft. B. M. of \$15.47 for this labor. As there was 365 cu. yds. in an arch this gave a cost of \$1.06 per cu. yd. for this labor.

Concrete.—In mixing and placing the concrete for the arches, one rib was done in a day so that it would be monolithic. There

were 73 cu. yds. in a rib. The following was the cost of labor per day when mixing and placing was being done:

1 Foreman	\$ 5.00
1 Sub-foreman	3.50
1 Engineman	3.50
1 Man running mixer.....	2.50
1 Concrete placer.....	2.75
4 Concrete placers, at \$2.50.....	10.00
4 Men on cars, at \$2	7.80
2 Men on mixer platform, at \$2.....	4.00
1 Man at stock pile.....	2.00
22 Men shovelling, at \$1.75.....	38.50
Total	\$79.55

The actual time of placing a ring was from 6 to 7 hrs., thus giving a cost of mixing and placing of 85 cts. per cu. yd. When the concrete work was done, some of the crew was knocked off, and the rest were kept busy in changing tracks and other details. As stated, a larger ring could have been placed in a day, but the

Fig. 25.—Casting Concrete Arch Rings.

risk of some unforeseen accident that might have held up the work was considered too great to take. Fig. 25 shows how these rings were cast.

Cost of a Concrete Ribbed Arch Bridge at Grand Rapids, Mich.*—The bridge consisted of seven parabolic arch ribs of 75 ft. clear span and 14 ft. rise. The five ribs under the 21-ft. roadway were 24 ins. thick, 60 ins. deep at skewbacks and 25 ins. deep at crown ;

**Engineering-Contracting*, Jan. 8, 1908.

the two ribs under the sidewalks were 12 ins. thick and of the same depth as the main ribs. Each rib carried columns which supported the deck slab. Columns and ribs were bound together across bridge by struts and webs. All structural parts of the bridge were of concrete reinforced by corrugated bars. The abutments were hollow boxes with reinforced concrete shells tied in by buttresses and filled with earth. There were in the bridge including abutments 884 cu. yds. of concrete and 62,000 lbs. of reinforcing metal or about 70 lbs. of reinforcing metal per cu. yd. of concrete. Of the 884 cu. yds. of concrete 594 cu. yds. were contained in the abutments and wing walls and 290 cu. yds. in the remainder of the structure.

Centers.—The center for the arch consisted of 4-pile bents spaced about 12 ft. apart in the line of the bridge. The piles were 12 x 12 in. x 24 ft. yellow pine and they were braced together in both directions by 2 x 10-in. planks. Each bent carried a 2 x 12-in. plank cup. Maple folding wedges were set on these cups over each pile and on them rested 12 x 12-in. transverse timbers one directly over each bent. These 12 x 12-in. transverse timbers carried the back pieces cut to the curve of the arch. The back pieces were 2 x 12-in. plank, two under each sidewalk rib and four under each main rib of the arch. The back pieces under each rib were X-braced together. The lagging was made continuous under the ribs but only occasional strips were carried across the spaces between ribs. This reduced the amount of lagging required but made working on the center more difficult and resulted in loss of tools from dropping through the openings. Work on the centers and forms was tiresome owing both to the difficulty of moving around on the lagging and to the cramped positions in which the men labored. Carpenters were hard to keep for these reasons.

Concrete.—A 1 : 7 bank gravel concrete was used for the abutments and a 1 : 5 bank gravel concrete for the other parts of the bridge. The concrete was mixed in a cubical mixer operated by electric motor and located at one end of the bridge. The mixed concrete was taken to the forms in wheelbarrows. The mixture was of mushy consistency. No mortar facing was used but the exposed surfaces were given a great work. In freezing weather the gravel and water were heated to a temperature of about 100° F.; when work was stopped at night it was covered with tarred felt and was usually found steaming the next morning.

The cost data given here are based on figures furnished to us by Geo. J. Davis, Jr., who designed the bridge and kept the cost records. Mr. Davis states that the unit costs are high, because of the adverse conditions under which the work was performed. The work was done by day labor by the city, the men were all new to this class of work, the weather was cold and there was high water to interfere, and work was begun before plans for the bridge had been completed so that the superintendent could not intelligently plan the work ahead. Cost keeping was begun only after the work was well under way. Many of the items of cost were incomplete in detail.

The following were the wages paid and the prices of the materials used:

Materials and Supplies—

No. 1 hemlock matched per 1,000 ft.....	\$20.00
No. 1 hemlock plank per 1,000 ft.....	17.00
No. 2 Norway pine flooring per 1,000 ft.....	19.00
No. 2 yellow pine flooring per 1,000 ft.....	20.00
12 x 12 in. x 16 ft. yellow pine per 1,000 ft.....	29.00
12 x 12 in. x 24 ft. yellow pine piling per 1,000 ft..	27.00
Maple wedges per pair.....	.50
1/2-in. corrugated bars per 100 lbs.....	2.615
3/4-in. corrugated bars per 100 lbs.....	2.515
1-in. corrugated bars per 100 lbs.....	2.515
Coal per ton.....	4.00
Electric power per kilowatt.....	.06
Medusa cement per bbl.....	1.75
Aetna cement per bbl.....	1.05
Bank gravel per cu. yd.....	.85
Sand per cu. yd.....	.66
Carpenters, per day.....	\$3 to 3.50
Common labor, per day.....	1.75

The summarized cost of the whole work, with such additional costs as the figures given permit of computation, was as follows:

<i>General Services—</i>	Total.	Cu. Yd.
Engineering	\$451	\$0.512
Miscellaneous	75	0.004
<i>Pumping—</i>		
Coal at \$4 per ton.....		\$210
Machinery, tools and cartage.....		282
Labor		497
Total, 110 days, at \$9.....		\$990
<i>Excavation—</i>		
	Total Cost.	
Timber, cartage, etc.....	\$ 376	
Tools	69	
Labor at \$1.75.....	1,657	
Total	\$2,102	
<i>Piling (5,711 cu. yds.)—</i>		
	Total	Per cu. yd.
Earth	\$1,142	\$0.20
Labor, including riprapping.....	396	0.07
Total	\$1,538	\$0.27
<i>Removing Old Wing Walls—</i>		
	Total	
Labor and dynamite.....	\$246	
Tools and sharpening.....	64	
Total	\$310	
<i>Hand Rail (150 ft.)—</i>		
	Total	Per lin ft.

	Total.	Per cu. yd.
Forms	\$ 3,312	\$ 3.75
Concrete	\$ 5,532	\$ 6.25
Grand total	\$18,113	\$20.50

In more detail the cost of the various items of concrete work was as follows for the whole structure, including abutments, wing walls and arch, containing 584 cu. yds.:

<i>Form Construction—</i>		Total.	Per cu. yd.
Lumber and cartage.	\$1,547		\$1.75
Nails and bolts.	129		0.16
Tools	110		0.12
Labor, erecting and removing.	1,524		1.72
Total	\$3,312		\$3.74

<i>Concrete Construction—Materials—</i>			
Medusa cement, at \$1.05.	\$1,218		\$1.37
Ætna cement, at \$1.75.	499		0.56
Sand, at 66 cts. per cu. yd.	37		0.04
Gravel, at 85 cts. per cu. yd.	915		1.04
Total materials	\$2,669		\$3.01

<i>Mixing—</i>			
Machinery and supplies.	\$ 569		\$0.62
Power, at 6 cts. per kw.	52		0.06
Tools	22		0.02
Labor	737		0.83
Total mixing.	\$1,380		\$1.53
Placing concrete.	\$ 609		\$0.69
Tamping concrete.	\$ 481		\$0.54

Heating Concrete—

Apparatus and cartage.....	\$ 47	\$0.05
Fuel	96	0.11
Labor	270	0.31
Total heating	\$ 413	\$0.47
Grand total.....	\$8,844	\$9.98

Considering the abutment and wing wall work, comprising 594 cu. yds. separately, the cost was as follows:

<i>Forms—</i>	Per cu. yd.
Materials	\$1.20
Labor	1.09
Total	\$2.29
<i>Concrete—</i>	
Materials	\$2.92
Labor	2.28
Total	\$5.20
Heating water and gravel.....	\$0.70
Grand total.....	\$8.29

Considering the arch span, comprising 290 cu. yds. separately, the cost was as follows:

<i>Forms—</i>	Per cu. yd.
Materials	\$ 3.70
Labor	3.03
Total	\$ 6.73
<i>Concrete—</i>	
Materials	\$ 3.33
Labor	3.57
Total	\$ 6.79
Grand total.....	\$13.52

Cost of Centering of a 233-ft. Arch.—In *Engineering-Contracting*, Jan. 6, 1909, are given design and data relating to the Walnut Lane Bridge, Philadelphia, as furnished by Mr. George H. Heller. Only a brief summary of the article is given here.

Dimensions of Arch.—The main arch of the Walnut Lane bridge consists of two arch ribs, each 18 ft. wide at the crown and 21 ft. 6 ins. wide at the skewback; these ribs are spaced 34 ft. c. to c., and are 5 ft. 6 ins. deep at the crown and 9 ft. 6 ins. deep at the skewback; the span is 233 ft. in the clear, and the height of the soffit at the crown above the springing line is 70 ft. 3 ins.

The two main ribs carry spandrel piers and a series of spandrel arches upon which the spandrel walls are built up to the height to receive the floor, which consists of steel beams with concrete arches between, and it is upon this floor that the roadway and sidewalk paving is laid, the roadway being 40 ft. wide and the two sidewalks each 8 ft. wide. The height of the soffit of the arch above the surface of the creek is about 136 ft., while the roadway of the bridge is about 14 ft. higher, making about 150 ft.

It is necessary, while considering the nature of the design (Fig. 28), to remark the fact of the arch itself being composed

of two independent and separate ribs. This feature allowed the construction of each rib by itself and so presented an opportunity of reducing the cost of the centering by permitting one arch rib to be constructed first on centering necessary for one rib, and then, when the arch is completed, to move the same centering transversely so as to serve for the construction of the adjacent arch rib. This feature of construction was embodied in the design, and it was found not only to be feasible but also simple and easy of action, even though the mass of timbering was so great and covered so large an area. It was also thought proper to use steel in the construction of the bottom of the centering, for, as a material, it afforded better facilities for making joints capable of withstanding possible vibration in moving, and it formed a firm foundation, all parts of which acted together as a unit and allowed the whole mass to be moved true to line and without distortion or accident to its new position.

Section of A

Fig. 26.—Centering for Walnut Lane Bridge.

Beginning with the base of the centering, the steel trestle supports were spaced 24 ft. and 30 ft. apart and were carried on concrete piers founded upon and doweled into the solid rock. These piers were carried up to a uniform height above all danger of freshet, and they formed the basic foundation upon which the whole mass of steel and timber was designed to move. Each steel trestle was securely anchored into its pier by $1\frac{1}{2}$ -in. steel rods, and these rods served to guard against freshets and wind and were released when the centering was moved.

The movement of the centering was accomplished by placing on each pier a series of ten steel rollers, each 6 ins. in diameter, rolling on steel plates built into the tops of the piers; each roller was capable of bearing in safety 10 tons, making 100 tons, which was the total maximum weight at the center pier to be moved. The steel bents rested upon these rollers, and upon completion of the erection of one rib of the arch they were all moved in unison by placing jacks between the bottom end of each steel bent and a studded anchor chain which formed a cradle or saddle against which

the jack worked, the ends of the chain being attached to timbers previously built into the piers for that purpose; this method of translation proved to be quite effective, and the whole distance of 34 ft. was covered in the space of three days.

The total weight moved can be fairly stated to be about 1,000 tons. This amount is found by taking the total weight of bolts, steel trestle and timber trestle, and allowing in the case of timber 5 lbs. per ft. B. M., the timber being probably very heavy from the absorption of water from the structure. This great weight, covering a length of say, 230 ft., and a width of 50 ft., was moved by jacks having a sum total capacity of 345 tons acting at 16 points.

Fig. 27.—Arch Centers.

The quantities of material used in the construction of the centering were:

Bolts, washers, nails.....	33,000 lbs.
Steel trestle and its floor.....	232,000 lbs.
Lagging and joists.....	38,000 ft. B. M.
Upper trestle and bracing.....	116,000 ft. B. M.
Lower staging and bracing.....	136,000 ft. B. M.
Concrete piers.....	1,000 cu. yds.

The cost was:

Timber	340,000 ft. B. M. at \$65.00	\$22,100
Metal	265,000 lbs. 04	10,600
Masonry	1,000 cu. yds. 10.00	10,000
Total		<u>\$42,700</u>

This centering served for two ribs, each containing 1,550 cu. yds., or a total of 3,100 cu. yds. Hence the centering cost \$13.80 per cu. yd. of concrete ribs.

The contract price for the Walnut Lane bridge was \$262,000.

Design of Center for a 50-ft. Span Masonry Arch.*—With the present high prices of lumber, the designing of timber centers for arches becomes a problem that requires careful study to save material and labor. In the accompanying drawing we show a center designed for a 50-ft. masonry arch railway bridge to be built in central Ohio. Owing to the excessive cost of pine in this section, oak will be used. This timber costs here about \$16 per M ft. B. M. The center, 26 ft. long, comprising two arch ribs, posts, caps, wedges and lagging, calls for 16,464 ft. B. M. of timber divided as follows:

	B. M.
2 x 4 ins. x 4 ft. lagging.....	1,554 ft.
140 2 x 12 ins. x 8 ft. 3 1/2 ins. straight ribs.....	2,322 ft.
20 2 x 12 ins. x 5 ft. 6 1/2 ins. straight ribs.....	222 ft.
20 2 x 12 ins. x 3 ft. 9 1/2 ins. straight ribs.....	112 ft.
20 2 x 12 ins. x 7 ft. curved ribs.....	420 ft.
60 2 x 12 ins. x 8 ft. curved ribs.....	1,440 ft.
40 2 x 12 ins. x 7 ft. braces.....	840 ft.
40 2 x 12 ins. x 7 ft. 6 ins. braces.....	900 ft.
10 2 x 12 ins. x 26 ft. bottom chord.....	1,920 ft.
40 2 x 12 ins. x 24 ft. bottom chord.....	960 ft.
40 2 x 12 ins. x 11 1/2 ft. fillers bottom chord....	1,280 ft.
20 2 x 12 ins. x 7 ft. fillers bottom chord.....	420 ft.
20 2 x 12 ins. x 21 ft. piece A.....	1,260 ft.
40 2 x 12 ins. x 3 1/2 ft. bottom chord end con....	280 ft.
20 10 x 12 ins. x 9 ft. posts.....	1,800 ft.
2 6 x 12 ins. x 38 ft. wall plates.....	456 ft.
2 8 x 12 ins. x 38 ft. caps.....	608 ft.
Total	16,464 ft.

660 1/2 x 9 in. bolts for ribs.
 320 1/2 x 9 in. bolts for bottom chord.
 120 1/2 x 13 in. bolts for end con. bottom chord.
 160 1/2 x 15 in. bolts for piece A.

Figure 27 shows the framing very clearly. With carpenters receiving \$4 per day it is estimated that the framing and erecting will cost about \$12 per M ft. B. M., including iron. The cost of bolts and nuts will run about \$1.50 per M ft. B. M. Roughly, then, this center will cost about \$36 per M ft. B. M. in place. The center was designed by Mr. J. H. Milburn, Chief Draftsman, Office of the Chief Engineer, Baltimore & Ohio, R. R., Baltimore, Md.

Data on a Concrete Viaduct.—A reinforced concrete viaduct 2,800 ft. long has been recently built by John T. Wilson, of New York, for the Richmond & Chesapeake Bay Ry. Co., at Richmond, Va. It ranges in height from 18 ft. at each end to 70 ft. at the center. The reinforced concrete girders range in length from 23 1/2 ft. to 67 1/2 ft. c. to c. of bents. The bents are two-post bents, with legs 2 ft. square. The largest girder, having a length of 67 1/2 ft., weighs 54 tons, its cross-section being 20 x 70 ins. In this viaduct there were 2,650 cu. yds. of concrete, and it required 172 ft. B. M. of timber for the forms and falsework per cubic yard of concrete. Kahn bars were used for reinforcing. The forms on the sides of the girders were removed at the end of 7 days, but the column forms and those supporting the girders were not removed for at least 30 days. While it is a single track viaduct, it is so designed that, by adding another series of posts and girders, it can be made

*Engineering-Contracting, Nov. 14, 1906.

into a double track viaduct. One little trick in filling the column forms is worth bearing in mind. They were built U-shaped, the fourth side being left open, and built up as fast as the concrete was poured in from that side. This method facilitated working the concrete in around the reinforcing bars. Mr. J. H. McLure is Chief Engineer of the R. & C. B. Ry.

Cost of a Concrete Trestle and Three Concrete Girder Bridges With Abutments.*—The reinforced concrete trestle and the three bridges with concrete abutments that are referred to in this article were constructed near Easton, Pa., by Mr. M. P. McGrath, general contractor, of that place. The contractor or his engineer, Mr. J. F. Mooney, supervised the work so that while one man was employed nominally as a foreman and received \$2.75 per day, he worked like

Fig. 28.—Details of Girder Rail Fastenings.

the other laborers; generally he was charged to placing or finishing. The costs given are actual costs except for the form lumber, which had been used before and the cost of which was approximated. The costs are given separately for each structure.

Coal Trestle.—The trestle was designed as a coal trestle and was constructed as shown by Figs. 28 and 29, except that the bents instead of being made solid, were built with a 4 x 8-ft. opening in each to permit the coal to flow more readily. There were 8 bents and two abutments and the trestle was 114 ft. long. It was designed to carry the rails directly on the girders without cross-ties, so that the girder reinforcement was made quite heavy, as is clearly shown by the drawings. It will also be seen that the rails had their bases partly embedded in the girders and were fastened by chairs. The chairs were of cast iron and were held by

**Engineering-Contracting*, Feb. 5, 1908.

FIG. 29.—Concrete Trestle.

bolts extending down into the girder and secured under the lower reinforcement bar. The chairs were spaced 2 ft. apart, those of one rail being staggered with those of the other rail. This construction gave excellent results in operation and saved some 6 in. in height over the ordinary cross-tie construction. The remaining structural details and dimensions of the trestle are clearly shown by Figs. 28 and 29.

The wages paid on this trestle and also on the bridge construction described later, were as follows:

Laborers, per 10-hour day.....	\$1.50
Blacksmiths, per 10-hour day.....	2.00
Engineman, per 10-hour day.....	1.70
Carpenter, per 10-hour day.....	2.00
Foreman, per 10-hour day.....	2.75

The location of the trestle being almost flush against a railway embankment and it being necessary to locate the stock piles some 150 ft. from the mixer, made the cost of wheeling the materials high. The mixer was set up at the center point of the trestle and discharged into barrows which were hoisted by a pole and yard arm. The pole was provided with a yard and had a three-quarters swing. A rope passing over a pulley at the end of the yard arm was provided at one end with a three-line sling provided with a hook to attach to the wheel and two rings to slip over the handles. This rope hoisted the barrows to the top of the trestle by means of a horse hitched to the free end. The concrete used for the reinforced girders was a 1-2-4 mixture, the other parts of the trestle were made of 1-2-6 concrete in which were embedded stones ranging from the size of a man's head to the size of a half-barrel; these rubble stones were thrown into the forms in 1½-ft. layers. The total amount of concrete in this trestle was 116 cu. yds. and its cost was as follows:

Materials—	Per cu. yd.
1,069 bbls. cement, at \$1.24.....	\$1.325
0.831 tons sand, at 70 cts.....	0.442
1.11 tons stone, at \$1.35.....	1.387
131½ lbs. steel, at 2 cts.....	2.630
Lumber (\$112.53 charged up).....	0.971
Total materials.....	\$6.755
Labor and Supplies—	
Making and erecting forms.....	\$1.21
Handling sand.....	0.150
Handling stone.....	0.176
Mixing concrete.....	0.184
Placing concrete.....	0.300
Finishing concrete.....	0.103
Miscellaneous	0.240
Total labor.....	\$2.398
Total labor and materials.....	\$9.153

In the item miscellaneous were included blacksmith's work on reinforcement, handling cement, coal, oil, etc. As will be noted

the cost of reinforcement is distributed over the whole structure 116 cu. yds. of concrete; to be strictly accurate, the total 15,250 lbs. of reinforcing metal should be divided into the volume of concrete in the girders which, figured from the drawings, was approximately 24 cu. yds. This gives the great weight of 635 lbs. of reinforcement per cubic yard of concrete in the girders.

Bridge No. 1.—This structure had a clear span of $10\frac{1}{2}$ ft. and consisted of two concrete girders, one under each rail, with ends embedded into concrete abutments with wing walls. The girders were 3 ft. deep, 2 ft. wide on top and $1\frac{1}{2}$ ft. wide on the bottom and each was made of 1:2:4 concrete reinforced by five $1\frac{1}{2}$ -in. round bars, three straight and two bent, with stirrups every $1\frac{1}{2}$ ft. The abutments were made of 1:2:6 concrete. Conditions were favorable construction. As in the trestle rubble stones were incorporated in the abutment concrete; some cinders were also used and their cost is included in the cost of handling the stone. The bridge contained altogether 102 cu. yds. of concrete. The costs were as follows:

<i>Materials—</i>	<i>Per cu. yd.</i>
Cement	\$1.264
Stone	1.588
Sand	0.444
Reinforcement	0.098
Lumber	0.883
Total materials.....	\$3.877
<i>Labor and Supplies—</i>	
Forms	\$0.479
Handling stone.....	0.175
Handling sand.....	0.077
Mixing concrete.....	0.100
Placing concrete	0.176
Finishing concrete.....	0.094
Miscellaneous	0.224
Total labor	\$1.325
Total materials and labor.....	\$5.202

The item miscellaneous includes hauling cement and water, work on reinforcement and coal. As in the trestle, the unit cost of reinforcement is got by dividing the total cost into the total yardage of concrete value as only the girders were reinforced.

Bridge No. 11.—This bridge had a clear span of 16 ft. and was 13 ft. high, and like the bridge just described consisted of two concrete girders with ends embedded into concrete abutments. The girders were 22 ins. deep, 2 ft. wide on top and 1 ft. wide on the bottom. Each girder was reinforced with five $1\frac{1}{2}$ -in. round rods, three straight and two bent, without stirrups. The ties were fastened to the girders by embedded anchor bolts. The costs of materials changed somewhat from those given for the trestle and bridge No. 1. The cement cost \$1.54 per barrel, and the stone (crushed on the ground) cost 73 cts. per ton. Rubble stones were incorporated in the abutment concrete as in the work previously described; this stone had all to be collected by men and teams and

this fact is reflected in the high unit cost of handling stone. The mixer was located so that its discharge chute overhung and discharged directly into the forms for one abutment. To reach the further abutment an ordinary coal chute was provided and the concrete chuted directly into place. The bridge contained 98 cu. yds. of concrete, which cost as follows:

<i>Materials—</i>	<i>Per cu. yd.</i>
Cement, at \$1.54.....	\$1.596
Stone	0.814
Sand	0.459
Reinforcement	0.176
Lumber	0.316
Total materials	\$3.355
<i>Labor and Supplies—</i>	
Forms	\$0.526
Handling stone.....	0.236
Handling sand.....	0.180
Mixing concrete.....	0.073
Placing concrete.....	0.157
Finishing concrete.....	0.092
Coal and water.....	0.041
Handling cement	0.078
Total labor.....	\$1.377
Total materials and labor.....	\$4.732

It will be noted that the cost of handling the stone for this bridge ran high because of the teaming referred to above. Reinforcement is charged into the total yardage as in the structures previously described.

Bridge No. III.—This bridge was built for the passage of farm wagons of 5 tons capacity. It had a clear span of 17 ft. and was 15 ft. wide and 17 ft. clear height. The floor consisted of four 12 x 6-in. girders carrying a 6-in. floor slab. The concrete was a 1:2:6 mixture throughout and was mixed by hand. The concrete was made with a broken tile aggregate obtained from a nearby tile works at the cost of handling only. This tile was very easily broken and left a rather poor finish to the concrete. There were 107 cu. yds. of concrete in the bridge and it cost as follows:

<i>Materials—</i>	<i>Per cu. yd.</i>
Cement	\$1.594
Sand	0.459
Reinforcement	0.127
Lumber	0.280
Total materials.....	\$2.460
<i>Labor and Supplies—</i>	
Forms	\$0.41
Handling tile.....	0.692
Handling sand.....	0.112
Handling cement.....	0.105
Mixing concrete.....	0.413
Placing concrete.....	0.341
Total labor.....	\$2.077
Total materials and labor.....	\$4.537

In noting these costs the very heavy cost of handling the broken tile aggregate will be observed; on the other hand this aggregate cost nothing itself. The lumber charge is only that for new lumber, the old lumber that was re-used was not charged in. The cost of sand was 94 cts. per ton.

Cost of a Reinforced Concrete Trestle.—Mr. C. C. Mitchell gives the following data:

The trestle replaced an old wooden trestle 286 ft. long on a cable incline railway up Catskill Mountain, New York. The main structural features of the trestle and the slope of the ground on which it was built are indicated by Fig. 30. The work was done by contract after the cable incline had closed down on Oct. 17, 1908, for the season. Parts of the old timber structure were thus available for supporting forms and for such other purposes as the contractor required this kind of timber.

Fig. 30.—Concrete Trestle.

While waiting for the materials to arrive and the road to close down, excavation was begun on the footings, stone for the concrete was broken, a pipe line 1,000 ft. long was laid to a waterfall, a cement house and a shanty in which to fabricate the steel were built.

In excavating for the footings it developed that there were alternate strata of slate rock and earth, with boulders in about half of them, so that to get a good foundation on bedrock it was necessary to go from 4 to 10 ft. below the ground, the surface of which was so steep that it was very difficult to work on it. Slides and caving caused a much larger quantity of material to be handled than that represented by the holes excavated.

The excavations were walled up in pyramidal form on a batter of 2 ins. to the foot outward to within 2 ft. of the ground surface, there narrowing to a section 30x30 ins., on top of which a wooden box 30 ins. square and 24 ins. high was set up. Every bent had two such forms for the batter post footings, and every alternate

bent had in addition a third for the diagonal bracing struts to meet on. Then footings were concreted with a mixture of 1-3-6, the stone being broken by hand to 1½-in. size and the wooden top forms being shifted ahead as the work progressed, the stone-breaking, mixing board, etc., being likewise shifted ahead. Half of the lumber was stored at the lower end of the trestle and half at the middle; half of the sand at the middle and half at the upper end; half of the steel at the lower end and half at upper end, and all cement at the middle.

Five mixing boards were established along the trestle, and stone was broken successively at each as it was needed for the concrete. The water pipe, which ran alongside, was shortened as the work progressed. The sand and gravel were separated by screening and sent to the mixing boards through temporary chutes, the superstructure concrete being 1 part cement, 2 parts sand, 2 parts ¾-in. gravel and 2 parts ¾-in. stone.

Work was begun with a force of 16 men working 9 hours, of whom 1 was a foreman drawing \$4 a day, 1 carpenter at \$2.50, 1 steel bender at \$2.25, and 7 laborers at \$1.75 each. When the road closed down the force was doubled, 3 more laborers being added at \$1.75 and 2 carpenters at \$2 and \$2.25, respectively, these latter working for a bonus.

Concreting the footings began on Oct. 18 and dismantling the old trestle at the same time, with some men fabricating steel, some building forms, some breaking stone and some excavating the upper footings.

The pulleys were first removed from under the cable, and the latter supported by 2x4-in. plank spiked to the old trestle bents, on which were also preserved the line and grade. The guard rails and track rails were next removed, then the cross ties and four inner stringers were unbolted and lowered by ropes to the ground and piled so as to form mixing boards. The remaining outside stringers were then shifted out to the ends of the bent caps, leaving a clear space in the center 8 ft. 6 ins. by 26 ins. deep. In some places the tops of these stringers were 2 ins. above grade and in other places 2 ins. below, otherwise they represented approximately the level for the new work and allowed a clearance of 3 ins. for the outside girder form of the new work. Next 2x6-in. spruce floor timbers for the girder forms were hung at 3-ft. intervals on a grade 27¼ ins. below by 2x4-in. battens spiked to the outside of the old stringers. The old bent caps were then gained out for each new girder to the grade of the floor timber, and a 1¼x12-in. by 16-ft. bottom board for each of the three new girder forms nailed in place. These girder forms were then built up to a depth of 26 ins. of 1¼x9-in. spruce matched boards, 1¼x4-in. pieces being used for battens every 36 ins. These sides were braced internally at 3-ft. intervals by tablets taken from the footing forms and placed like cross-partitions between the girder forms. The outer sides were braced by wedging against the 2x4-in. hangers and old supporting stringers, the tops of the latter being held from gaping outward by 1¼x4-in. strips nailed across the top over the floor timbers. The

three floor timbers at the center of each span were then further supported from below by struts composed of old ties and braces from the dismantled structure.

The forms for the batter posts and bracing struts were made up in trough form, leaving the outer and upper side open, then set in place on the foundation, and the tops sawed to fit the bottom of the girder forms. The webs were then built between their tops, uniting the whole with the girders. The post and strut forms were then properly braced and supported, the reinforcing steel put in place, a section of the fourth side put in place and the whole securely clamped together by $\frac{1}{2}$ x 16-in. bolts passing tangent to two sides and drawing 2 x 4-in. yokes against the remaining two sides.

The reinforcement having been placed in the girders, the concrete was then poured in and carefully rammed and spaded, and the third side built up and clamped directly ahead of the concreting so as to permit the most careful placing of the latter without chance of displacing the reinforcement. These posts were concreted together up to the level of the girders for two bents usually. Owing to the 30° surface, the tops of the girders had to be boarded over continuously as the concreting progressed to keep it from running out, and a section of 1-in. pipe had to be left in place every 4 ft. in the outer girders through which to bolt the track to the new structure. When concreting stopped for the day bulkheads in the form of saddles were placed in the web at a bent, these bulkheads being removed the next day, allowing the concrete of each girder on the succeeding day to begin half way in the web of the preceding **RAIL**.

Each batter post was reinforced by a rack composed of $\frac{1}{2}$ -in. rods wired to dowels in the footing or let into holes drilled in bed-rock, extending up through the girder above it nearly to the top surface and bound together every 18 in. by a rectangular hoop of $\frac{1}{2}$ -in. corrugated bar, previously bent to the right form and securely wired together. These racks were made up as needed, and when set in place inside the forms had about 1 in. of clearance around them and had to be constantly watched by the man ramming the concrete to keep them centered. Each strut brace had a $\frac{1}{2}$ -in. rod within 1 in. of each of its two lower corners, wired to the footing dowels and passing up through the central girder nearly to the surface, and requiring great care in placing the concrete to maintain them in place.

Each girder had two $\frac{1}{2}$ -in. bars suspended from the cross-batters on top of the forms by wire, so that they lay $1\frac{1}{2}$ in. below the upper surface continuously, and two intermediate 3-ft. bars over each web for continuity. At 6-in. intervals eleven stirrups were hung on them at the bent webs and two more were hung near the center of span, so that they lay in V-shape normal to the axis of each girder and 1 in. distant from its bottom and sides. Four $\frac{1}{2}$ -in. bottom bars were then hung or laid in these stirrups, the length being 34 ft.; two were made to break joints at each bent. When these bars were all in place and securely wired, two $\frac{1}{2}$ -in. bars were sprung into the cross-struts at the center of span and four more in

each of the webs and wired in place. Whereupon the girders were ready for concreting.

The congestion of steel at the webs made it difficult to place the concrete and properly ram it at and near the webs, and particularly to place and remove bulkheads and clean out the forms before going ahead with the concreting. It was also hard to place the concrete in the top of the bracing struts. The best results in placing the concrete were attained with a very wet mix, poured so that the water would flow up the forms ahead and be followed by a grout, which ran all around and between the reinforcement, leaving the stone and gravel to be rammed down into it at last.

The mixing was done by hand the gang being divided so that one batch was being separated while the other was being deposited. The sand and gravel were sent to the board by a chute, the stone broken at the edge of the board as used, and the cement carried to the board, each man taking a bag as he came to work and after lunch. Inclined runways of plank were shifted from bent to bent for the posts and others built from the mixing board to the top of structure and planks laid along the sides of the girder forms in such manner that the employees could return to the board without interfering with the loaded pails. Owing to the steepness of the ground and of the grade on the finished work, there was unusual danger of accidents and need of constant vigilance to prevent bad results from careless work, and this is the reason why only so many men were employed and in such a manner.

Because of the unexpected depth of thirteen of the footings, a $\frac{1}{2}$ -in. steel bar encased in 6 ins. of concrete was placed as a tie between the batter post feet wherever the latter did not reach directly to bedrock. This and 37 cu. yds. of extra concrete not indicated on the plans and a corresponding quantity of excavation not originally called for delayed the completion of the work, which was to have been finished on Dec. 1, so that it took until Dec. 12 to complete it. The weather was unusually favorable, being dry and warm until Nov. 3, from which time on there were light squalls of snow, succeeded by mild weather till Dec. 1, when it became so cold that the aggregates had to be heated. An old section of steel smokestack, 4 ft. in diameter and 12 ft. long, was filled with fire and sand and gravel piled over it, the water being heated in pails over a fire.

The 14 M. ft. of form lumber sufficed to complete about half the forms, and thereafter the forms first concreted, having been filled ten days, were stripped and the lumber used as the form work progressed. When the clamps were removed the post forms came off in four pieces in good shape to be set up again at once, but the girder and web forms had to be taken apart and rebuilt.

The top boards and tie strips were first pried off the top of the girders, the hangers and floor timber next removed, then the old stringers pried off and lowered with ropes, all the girder batters then knocked off, and the form boards taken off separately from both the outside and inside of girders, webs and struts. The bottom boards to the girders and diagonal strut braces were left in

place two weeks longer, with props under them, and then the old bent caps were sawed in two and the bent timber unbolted and dismembered, releasing the bottom boards, which were then removed, leaving the concrete completely stripped.

There was very little pointing necessary, except on the posts, which was done from a ladder, after which the exterior surfaces were given a wash of cement, alum and lye, rubbed in with a cement brick to waterproof the structure and remove board marks. The cable was blocked up on the concrete webs, the ties and guard rails bolted on, the pulleys rehung and track laid back in place by the Otis Railway Company, replacing track not coming under the contract.

The amount of work done under this contract was as follows: Excavation called for 37 cu. yds. earth, and extra excavation uncalled for 63 cu. yds. boulders, making a total of 100 cu. yds.; dismantling and piling 34 M. ft. yellow pine structure; 37 cu. yds. concreting (1-3-6) in extra footings; 125 cu. yds. concreting called for (1-2-4), reinforced; 13 tie rods for batter post feet; cleaning up and removal of debris; total cost, \$4,332.14; contract price, \$4,000; extras, \$677.75; total, \$4,677.75; profit on contract, \$245.61.

Daily records were kept, showing kind of weather, temperature, amount of each kind of work done, with proportion of pay roll spent in doing it and the unit cost noted down for the immediate purpose of more economically planning the next day's work. A distribution statement showed the cost of both labor and material, charged up against each item of work performed during the week and the unit costs computed for each. A comparison was made between weekly average and daily rates, and the conditions prevailing on those days showing the most economic rates were then planned for the succeeding week's work.

Separate records were kept for the items applying to the general contract, the costs on extra work being kept apart. Finally all the costs were referred to the quantity of work done under them in the form of unit prices per cubic yard and the percentage which each represented to the whole.

The itemized cost of the work is given in Tables XXII, XXIII and XXIV.

TABLE XXII.—Cost of Reinforced Concrete.

Materials—	Per cu. yd.
Cement	\$2.31
Sand	1.73
Stone	3.00
Gravel	0.33
Water	0.25
Total materials	\$6.72
Labor—	
Mixing and placing	\$1.94
Pointing up concrete	0.37
Waterproofing concrete	0.60
Total labor	\$2.91
Grand total concrete	\$9.63

Forms—

Lumber, butts and nails	\$4.75
Fabricating and erecting	3.58

Total forms\$8.33

Reinforcement—

Materials, bars, wire, etc.....	\$2.77
Fabricating	0.37
Placing	0.74

Total reinforcement\$4.88

Grand total for concrete work, 125 cu.
yds.\$22.84

Miscellaneous—

Excavation, 87 cu. yds.	\$0.56
Dismantling old trestle	1.00
Cleaning up at completion.....	0.40
General expenses, superintendence, etc.....	4.45

Total miscellaneous\$6.41

Grand total\$29.25

TABLE XXIII.—COST OF EXTRA FOOTINGS.

	Per cu. yd.
Excavation, 63 yds. rock, at \$2.89.....	\$ 4.91
Aggregates: Cement, \$1.94; sand, \$0.97; stone, \$1.01	3.92
Forms, material	1.20
Forms, labor	1.44
Concreting, labor	2.07
87 cu. yds. concrete	\$12.50

TABLE XXIV.—THIRTEEN EXTRA TIE RODS.

	Per cu. yds.
Excavation	\$ 4.01
Bending and placing steel rods.....	7.80
Form labor	9.35
Form material	2.20
Reinforcement (steel bars), $\frac{1}{2}$ in.....	5.10
Concreting labor	5.00
Aggregates: Cement, \$2.70; sand, \$1.35; stone, \$3..	7.00
1 $\frac{1}{2}$ yds. concrete	\$47.50

These tie rods were of concrete, 6x6 ins., reinforced by $\frac{1}{2}$ -in. steel rods. The tie rods connected the feet of the batter posts, as shown in Fig. 80.

Standard Designs of Reinforced Concrete Culverts, C., B. & Q. Railway.*—Standard culvert designs for use on the Chicago, Burlington & Quincy Ry. have been worked out in reinforced concrete for box culverts ranging from 4x4 ft. to 10x12 ft. in size and for arch culverts from 4x4 ft. to 6x6 ft. in size. Up to and including in box culverts clear openings 7 ft. wide the pattern of structure shown by Fig. 31 is used; for clear openings of 8 ft., and over, the

**Engineering-Contracting*, Oct. 3, 1906.

TABLE XXV.
Box Culverts. Pattern Fig. 31.

Inside dimensions in ft.	Length of wing walls Ft. Ins.	Cu. yds. concrete wing walls.	Cu. yds. conc., Lin. ft. Barrel.	Thick-ness side walls. Ins.	Thick-ness roof slab. Ins.	Thick-ness floor slab. Ins.

10 x 12.....	20-4	76.0	3.2	18	24	24

pattern is modified as shown by Fig. 32. Figure 33 shows the pattern of arch structure used. The dimensions L and I in the box culvert designs are determined by the formulas,

$$L = \frac{10}{3} A + x + 3 \text{ ft.}; \text{ and}$$

$$I = \frac{10}{3} A + x.$$

Fig. 31.

TABLE XXVI.

Inside dimensions in ft.	Length of wing walls Ft. Ins.	Cu. yds. concrete in wing walls.	Lbs. of metal wing walls.	Cu. yds. conc. per lin. ft. barrel.	Lbs. of metal per lin. ft. barrel.
4 x 4.....	5-3	6	236	0.5	54
5 x 5.....	6-11	10	401.7	0.71	76.7
6 x 6.....	8-6	12	553.5	1.00	102.4

in which x = the width of roadbed at crown and A = the height of the fill above the culvert. In the arch culvert pattern the dimension L is determined by the formula,

$$L = \frac{10}{3} A + x + 4 \text{ ft.}$$

Fig. 32.

All other dimensions are determined by the cross-sectional size of the waterway. They are, for the various sizes adopted and with the exception of the reinforcement, shown in Table XXV.

Structural details of the 4x6-ft. culvert of pattern Fig. 31 are shown in Fig. 34, and Fig. 35 shows the similar details for the 10x12-ft. culvert of pattern Fig. 2. The same general details are employed for the culverts of intermediate and smaller dimensions.

Fig. 33.

Turning now to the arch culvert pattern, Fig. 36 shows the structural details of the 6x6-ft. size. The main features of the other sizes of this pattern are shown by Table XXVI.

For culvert work the company uses a 1-3-6 concrete composed of 1.08 barrel of cement, 0.45 cu. yd. sand and 0.9 cu. yd. broken stone, or 1.25 barrels of cement and 1 cu. yd. of gravel.

Part Longitudinal Section. Sectional
End Elevation.

Fig. 34.

Cost of Concrete Culverts, References.—In *Engineering-Contracting*, Sept. 1, 1909, are given standard designs of box and arch culverts on the C. M. & St. P., together with quantities and costs. See Tyrrell's "Concrete Bridges and Culverts."

Cost of Reinforced Concrete Culvert.—The following data relative to the construction of a 4-ft. reinforced concrete box culvert in Missouri. The work was done under the supervision of P. S. Quinn, County Engineer. The culvert contained 28 cu. yds. of cement and 2,500 lbs. of steel bars. The concrete was a 1-4-8 mixture. Com-

men labor was paid 15 cts. per hour and carpenters 35 cts. per hour. The cost was as follows:

Material:	Total	Per cu. yd. Concrete.
Cement, 23 bbls., at \$1.50.....	\$ 34.50	\$1.28
Sand, 15 cu. yds., at \$0.65.....	9.75	.25
Crushed limestone, 28 cu. yds., at \$1.75....	49.00	1.75
Steel, 2,500 lbs., at 2.3.....	57.50	3.06
Lumber, delivered	33.60	1.20
Total material	\$184.35	58

Labor:

Carpenter, forms, 27 hrs.....	\$ 9.45	\$0.24
Helper, forms, 34 hrs.....	5.10	.13
Steel placing, 20 hrs.....	3.00	.11
Concrete, mix and place, 101 hrs.....	15.15	.54
<hr/>		<hr/>
Total labor	\$ 32.70	\$1.11
Grand total	\$217.05	\$7.75

The cost of placing the steel was \$0.0012 per lb.

Cost of an Arch Culvert.—The cost of a concrete arch culvert, 26-ft. span, 62-ft. barrel (exclusive of excavation), with wing walls and parapet, built near Pittsburg in 1901, was as follows, the concrete being 1 to 8 and 1 to 10, hand mixed:

	Per cu. yd.
0.96 bbl. cement, at \$1.60.....	\$1.535
1.03 tons coarse gravel, at \$0.19.....	0.195
0.40 ton fine gravel, at \$0.21.....	0.085
0.32 ton sand, at \$0.35.....	0.115
Tools, etc.	0.078
Lumber for forms and centers.....	0.430
Carpenter work on forms (23 cts. hr.).....	0.286
Carpenter work on platforms and buildings.....	0.050
Preparing site and cleaning up.....	0.210
Changing trestle	0.085
Handling materials	0.037
Mixing and laying, av. 15½ cts. per hr.....	1.440
<hr/>	
Total per cu. yd.....	\$4.540

Wages per hour were: General foreman, 40 cts.; foreman, 25 cts.; carpenters, 22½ to 25 cts.; laborers, 15 cts. The finished structure contained 1,493 cu. yds., total cost being \$7,243, including \$463 for excavation. The work was done for a railway by company forces.

Cost of Six Arch Culverts and Six Bridge Abutments, N. C. & St. L. Railway.—Mr. H. M. Jones is authority for the following data: An 18-ft. full-centered arch culvert was built by contract on the N. C. & St. L. Ry., near Paris, Tenn. The culvert was built under a trestle 65 ft. high, before filling in the trestle. The railway company built a pile foundation to support a concrete foundation 2 ft. thick, and a concrete paving 20 ins. thick. The contractors then built the culvert, which has a barrel 140 ft. long. No expansion joints were provided, which was a mistake, for cracks have developed about 50 ft. apart. The contractors were given a large quantity of quarry spalls, which they crushed in part by hand, much of it being too large for the concrete. The stone was shipped in drop-bottom cars and dumped into bins built on the ground under the trestle. The sand was shipped in ordinary coal cars, and dumped or shoveled into bins. The mixing boards were placed on the surface of the ground, and wheelbarrow runways were built

up as the work progressed. The cost of the 1,900 cu. yds. of concrete in the culverts was as follows per cu. yd.:

1.01 bbls. Portland cement.....	\$2.26
0.56 cu. yd. of sand, at 60 cts.....	.32
Loading and breaking stone.....	.25
Lumber, centers, cement house and hardware.....	.64
Hauling materials04
Mixing and placing concrete.....	1.17
Carpenter work19
Foreman (100 days at \$2.50).....	.13
Superintendent (100 days at \$5.50).....	.29
	<hr/>
	\$5.29

It will be seen that only 19 cu. yds. of concrete were placed per day with a gang that appears to have numbered about 21 laborers, who were negroes receiving about \$1.10 per day. This was the first work of its kind that the contractors had done. It will be noticed that the cost of 42 cts. per cu. yd. for superintendence and foremanship was unnecessarily high.

The work in Tables XXVII and XXVIII was "company work" done by negro labor under company foremen.

TABLE XXVII.—Cost of Six Concrete Culverts on the N. C. & St. L. Ry.

No. of culvert.....	1	2	3	4	5	6
Span of culvert.....	5 ft.	7.66 ft.	10. ft.	12 ft.	12 ft.	16 ft.
Cu. yds. of concrete...	210	199	354	292	406	986
Ratio of cement to stone	1:5.5	1:6.5	1:5.8	1:5.8	1:6.1	1:6.6
Increase of concrete over stone	16.0%	9.9%	6.3%	12.3%	8.3%	5.2%
Bbls. cement per cu.yd.	1.02	0.90	1.06	1.01	1.00	1.09
Cu.yds. sand per cu.yd.	0.42	0.49	0.44	0.46	0.46	0.47
Cu.yds. stone per cu.yd.	0.86	0.90	0.95	0.89	0.94	0.94
Total days labor (incl. foremen and supt.)..	703	607	784	726	768	1,994
Av. wages per day (incl. foremen and supt.)	\$1.61	\$1.22	\$1.59	\$1.19	\$1.47	\$1.46
Cost per cu. yd.:						
Cement	2.18	1.94	2.27	1.82	2.11	2.01
Sand	0.17	0.20	0.18	0.18	0.19	0.14
Stone	0.52	0.52	0.47	0.54	0.47	0.58
Lumber	0.88	0.42	0.48	0.43	0.21	0.57
Unload. materials...	0.22	0.17	0.18	0.18	0.16	...
Building forms.....	1.07	0.32	0.62	0.47	0.72	0.41
Mixing and placing.	1.59	1.74	1.69	1.25	1.23	1.26
	<hr/>	<hr/>	<hr/>	<hr/>	<hr/>	<hr/>
Total per cu. yd..	\$4.65	\$5.20	\$5.89	\$4.97	\$5.19	\$4.97

Note:—All these arches were built under existing trestles, and in all cases, except No. 2, bins were built on the ground under the trestle and the materials were dumped from cars into the bins, loaded and delivered from the bins in wheelbarrows to the mixing boards, and from the mixing boards carried in wheelbarrows to place. Negro laborers were used in all cases, except No. 5, and

were paid 90 cts. a day and their board, which cost an additional 20 cts.; they worked under white foremen who received \$2.50 to \$3 a day and board. In culvert No. 5, white laborers, at \$1.25 without board, were used. There were two carpenters at \$2 a day and one foreman at \$2.50 on this gang, making the average wage \$1.47 each for all engaged. The men were all green hands, in consequence of which the labor on the forms in particular was excessively high. The high rate of daily wages on culverts Nos. 1 and 3 was due to the use of some carpenters along with the laborers in mixing concrete. The high cost of mixing concrete on culvert No. 2 was due to the rehandling of the materials, which were not dumped into bins but onto the concrete floor of the culvert and then wheeled out and stacked to one side. The cost of excavating and back-filling at the site of each culvert is not included in the table, but it ranged from 70 cts. to \$2 per cu. yd. of concrete.

TABLE XXVIII.—COST OF CONCRETE ABUTMENT, RETAINING WALLS AND FOUNDATIONS.

No. of structure.....	7	8	9	10	11	12
Cu. yds. of concrete.	310	99	282	78	71	72
Ratio of cement to stone	1:5.7	1:6.3	1:5.9	1:6.6	1:5.7	...
Increase of concrete over stone	5.2%	10.0%	12.8%	4.0%	10.9%	...
Bbls. cement per cu.yd.	1.09	0.95	0.99	0.96	1.03	1.39
Cu.yds. sand per cu.yd.	0.47	0.45	0.44	0.51	0.45	0.54
Cu.yds. stone per cu.yd.	0.94	0.91	0.90	0.96	0.90	1.09
Total days labor (incl. foremen)	573	226	599	128	131	224
Av. wages per day (incl. foremen).....	\$1.43	\$1.88	\$1.46	\$1.69	\$2.05	\$1.55

Cost per cu. yd.:

Cement	\$2.32	\$1.66	\$1.93	\$2.07	\$2.19	\$2.95
Sand	0.19	0.18	0.18	0.31	0.18	0.17
Stone	0.52	0.18	0.22	0.48	0.18	0.65
Lumber	0.56	0.09	0.28	0.26	0.51	0.34
Building forms.....	0.35	0.40	1.09
Mixing and placing.	1.94	3.38	1.36	2.21	1.74	2.59
Totals	\$5.88	\$5.91	\$5.09	\$5.23	\$4.80	\$6.70

Note:—Structure No. 7 consists of two abutments to carry a 24-ft. span bridge made of I-beams. Bins to hold stone and sand were built on the railway embankment. At the head of the bin a part of the bank was dug away under the track, and long stringers put in to carry the track. The rock was dumped from the car into this opening and shoveled into the bin. The forms for the concrete were, of course, simpler than for the arches in Table XXVII; hence the labor on them cost less.

Structure No. 8 consists of concrete side walls to support a cedar cover, forming a culvert. Slag was used instead of crushed stone in this structure as well as in Nos. 9 and 11.

Structure No. 9 is a retaining wall. There was much handling of materials due to lack of room for storage near the work. Old material was used for the forms.

Structures Nos. 10 and 12 are foundations for track scales. It is not clear why the labor cost of this work was so very high.

Cost of Reinforced Concrete Railroad Culvert in Montana.—In *Engineering-Contracting*, July 1, 1908, Mr. Henry A. Young gave the following: The following cost data were obtained from the Huntley Project of the U. S. Reclamation Service, located at Huntley, Mont., and show in detail the construction costs for a culvert carrying the canal under the Burlington & Missouri River R. R. The culvert was known as the "1st Culvert under the B. & M. R. Ry.," and was of a type similar to the designs of W. W. Colpitts, Assistant Chief Engineer, Kansas City, Mexico & Orient Ry., having two barrels, each barrel being 6 ft. 6½ in. x 7 ft. 6 in. and 24 ft. long. The roof was flat, the walls provided with fillets at top and bottom, and the entrance and outlet consisted of warped walls 20 ft. long opening into a canal section 20 ft. wide at bottom and having side slopes of 1½ on 1. The entire structure was of concrete, heavily reinforced with Johnson high carbon corrugated bars, 1 in. and ¾ in. in diameter.

The work was not done cheaply, and the figures are given to show the outside cost for this class of structure, built under the most unfavorable conditions. This was the first structure built on the project, the entire gang, mechanics and laborers, was green, and the work was done in November and December, 1905, the weather being very cold. An 8-hour day was worked. After the experience on this culvert the same gang did work for about two-thirds of the costs recorded here. The forms for the warped walls in this case gave considerable trouble.

A Municipal Engineering and Contracting Company's 1-8 cu. yd. cubical mixer was set about 50 ft. in front of the culvert. A gasoline pump took water from a creek 60 ft. away and delivered it to a tank near the mixer. The delivery pipe froze often and delayed the work. The mixer was fed by and the concrete was carried by wheelbarrows.

The concrete was put in wet and spaded. A 1-in. course of 1-2 mortar was placed on floor, copings, etc., and troweled. Chamfer strips were used on all sharp angles and fillets in culvert.

The earth was a sandy clay and was removed with slips, though considerable hand work was done in shaping up.

Sand and gravel were obtained from a pit about 1½ miles from the culvert. The wheel at pit was about 40 ft., the material being

screened into a bin. The haul was down hill. Cost delivered is recorded in table.

Cement, steel and other materials were hauled from a station about 1 mile from culvert.

The costs recorded do not include backfill, which was paid for under puddling, the trimming and finishing of exposed concrete walls, nor the construction and removal of a temporary railroad bridge. The work was done by contract, but actual costs are given whether borne by the contractor or the government, and no allowance is made for depreciation or for engineering expenses. The quantities consisted of 338 cu. yds. of excavation and 162 cu. yds. of reinforced concrete, the latter mixed in the proportion of 1-2½-5, the maximum size gravel being 2 ins.

Lumber was taken at its full cost, which is not absolutely correct, as it was later used over again on other structures. Probably one-third of the lumber charge would have been more nearly correct.

Excavation:	Days	Rate.	Total
Superintendent	3½	\$166.67	\$ 19.44
Foreman	5	50.00	2.33
Laborers (loading slips and excavat'g)	31½	2.00	63.75
2-horse teams, slip and drivers.....	8½	3.60	31.50

Summary of Concrete.

	Per Cu. Yd.
Material for forms.....	\$1.358
Labor on forms.....	2.306
Materials for concrete.....	4.714
Labor, mixing and placing	2.296
Steel for reinforcement.....	4.264
Hauling steel	0.100
Labor, bending steel.....	0.365
Labor, placing steel.....	0.444
Installing and removing plant.....	0.154
Superintendence and foreman.....	1.416

Total cost of concrete.....\$17.417

The cost of the steel reinforcement, in terms of the pound of steel as the unit, cost as follows:

	Per lb. Cts.
Steel bars	2.70
Hauling	0.06
Bending	0.23
Placing	0.28
Total	3.27

Cost of a Stone Arch Culvert.*—This culvert was erected by contract for the Chicago & West Michigan Ry., in 1891-1892. The culvert was built some distance from the original channel, and a new channel was cut through to the arch after it was completed. The excavation was carried 4½ ft. below water level. A cofferdam was built of 2x8 in. x 8 in. x 7 ft. sheet piling, which was driven by hand. Pumping was done with a centrifugal pump, the power being furnished by a traction engine. The pump was run only one-quarter of the time, for the water did not come in rapidly. All excavation was done by men with shovels and wheelbarrows.

*Engineering-Contracting, Jan., 1906.

The stone for the culvert was a sandstone scabbled at the quarry, and but little work had to be done on the top and bottom beds. Joints and beds were laid for 10 ins. back of the face with Portland cement, and the rest was laid with Louisville natural cement. Two derricks were used alternately and were run with steam power.

Work on the excavation commenced Oct. 5, 1891, a hand pump being used from Oct. 21 to 29; and a steam pump being used from Oct. 29 to Nov. 26, and from Jan. 29 to Feb. 2, 1892. The first stone was laid Nov. 7; the centers were raised Dec. 4; the keystone was finished Jan. 20; the last stone was laid Jan. 25; and the centers were struck Jan. 29. The plant was moved away Feb. 6. After Dec. 7, salt was used in hot water for mixing the mortar.

The following was the cost to the railway and to the contractor:

Prios Paid to Contractor.

1,041 cu. yds. dry excavation, at 25 cts.....	\$ 260.25
617 cu. yds. wet excavation, at 75 cts.....	462.75
594 cu. yds. excavation for channel, at 25 cts.....	148.50
16,740 ft. B. M. beech timber in foundation, at \$30.....	502.20
20,286 ft. B. M. 3-in. pine plank, at \$22.....	446.29
495.9 cu. yds. first-class masonry cut and placed (including cement and sand), at \$7.50.....	3,719.25
504 ft. B. M. sheet piling protection for ends of arch, at \$14.....	7.05
140 hours' work driving sheet piling and riprapping at end of arch, at \$0.15.....	21.00
20 hours, engine and engineman, ditto, at \$0.40.....	8.00
10% on \$29 labor.....	2.90
Total	\$5,578.19

Cost to C. & W. M. Ry.

481.9 cu. yds. sandstone, at \$6.82.....	\$3,284.95
Contractor's payment as above.....	5,578.19
Total	\$8,863.14

The above is the cost of sandstone f. o. b. La Porte. There were 57 carloads of stone, of 272.4 cu. ft. of stone per car, weighing 157 lbs. per cu. ft.

Actual Cost of Material and Labor.

Materials:

4,000 ft. B. M. 2 x 8 in x 7 ft. T. & G. sheet piling, at \$14.....	\$ 56.00
16,740 ft. B. M. beech timber, 12 in. thick, hewed, at \$10.....	167.40
20,286 ft. B. M. 3-in. pine plank in foundation, at \$14.....	283.92
1,300 ft. B. M. rough hemlock, 3 x 12 ins., in centers, at \$10.....	13.00
1,500 ft. B. M. pine (dressed 1 side), 3 x 12 ins., in centers, at \$14.....	21.00
1,400 ft. B. M. pine (dressed 1 side,) 2 x 4 ins., lagging, at \$14.....	22.40
Old timber in bents under center.....	10.00
Posts and walling for sheet piling (round timber).....	10.00
160 bolts in centers, $\frac{3}{4}$ x 12 ins., 200 lbs., at 4 cts.....	.00
3,000 boat spikes, $\frac{3}{4}$ x 7 ins., 1,000 lbs., at 2½ cts.....	25.00
65 cu yds. sand, at 75 cts.....	48.75
95 bbls. Louisville cement, at \$1.....	95.00
2 bbls. salt, at \$1.....	2.00
70 cords 16-in. wood, fuel for engines, at \$1.25.....	87.50

Total for materials..... \$931.97

Labor:

34	days foreman of laborers excavating, at \$2.....	\$ 68.00
76	days foreman of masons, at \$2.50.....	190.00
73 1/2	days engineman, at \$2.....	147.00
287 1/2	days stone cutters, at \$3.....	1,162.50
10	days carpenters, at \$2.....	20.00
622	days laborers, at \$1.50.....	933.00
23	days team, at \$3.....	69.00
Total for labor.....		\$2,589.50

General expense:

85	days timekeeper, at \$1.....	\$ 85.00
Repairs to stonecutters' tools.....		65.00
30	days traction engine and engineman, at \$3.....	90.00
60	days rent on engine when idle, at \$1.50.....	90.00
10% value of \$2,000 plant.....		200.00
Total general expense.....		\$530.00

Summary:

Total materials		\$ 931.97
Total labor		2,589.50
Total general expense.....		530.00
Grand total		\$4,051.47
Profit to contractor		1,526.72
Contract cost to railway.....		\$5,578.19

Itemized Cost.

Dry excavation	\$ 185.00 or 17.8 cts. per cu. yd.
Wet excavation and driving sheet piling	202.50 or 32.8 cts. per cu. yd.
Putting 16,740 ft. B. M. beech timber in place	40.00 or \$2.38 per M.
Putting 20,286 ft. B. M. plank in place	45.00 or \$2.22 per M.
Building and erecting centers....	31.00 or \$6.20 per M.
Unloading stone from cars	37.50 or \$0.07 1/2 per cu. yd.
Cutting stone, 496 cu. yds.....	1,282.25 or \$2.59 per cu. yd.
Setting stone, 496 cu. yds.....	483.50 or \$0.97 per cu. yd.
Handling and erecting plant.....	150.00
Excavating channel	110.25 or 18.6 cts. per cu. yd.
Sheet piling and riprap.....	22.50

The foregoing record, while very complete, would be more satisfactory if it contained a detailed statement of the organization of the forces. For example, how many masons, how many mortar mixers, how many masons' helpers on the wall, how many tag-men slewing the derrick boom, etc., were there to each derrick? Then, again, a sketch of the plant layout, and a rough drawing showing the general design of the culvert would be a valuable addition.

While the day of cut-stone arch culverts is rapidly passing away, such culverts are still specified. Concrete is cheaper than cut-stone masonry, but it is not always cheaper than rubble. We may expect to see a greater use of rubble masonry when engineers come to have a more detailed knowledge of costs.

If the contractor is left to himself, he can often build rubble masonry at less cost than concrete. Engineers, however, often draw

indefinite or very exacting specifications for rubble, and get, as a result, prices that are higher than for concrete. Rubble is particularly cheap where the job is small and where broken stone can not be hauled in except at great expense.

In considering the cost of excavation above given, it should be remembered that conditions were such that the material could be moved in wheelbarrows. If a derrick had to be used, the cost would have been much more.

Cost of Reinforced Concrete Subways.*—In 1903 the Lake Shore & Michigan Southern Ry. constructed, with its own workmen, three reinforced concrete subways at Elkhart, Ind., to carry a highway under its tracks and thus do away with grade crossings.

The three subways had a length of barrel 40 ft., 60 ft., and 160 ft. long, respectively, exclusive of wing walls. They were built as arches of 30-ft. clear span and 13-ft. headway, with a thickness of 28 ins. at the crown.

Steel bars of the Johnson corrugated pattern, made by the St. Louis Expanded Metal Fire Proofing Co., were used for the reinforcement, circumferential bars, spaced 6 ins. center to center, being laid $2\frac{1}{2}$ ins. from the extrados and intrados; across these were transverse rods, 2 ft. center to center, running the full length of the barrel. The steel rods were put in according to the Monier plan.

The concrete used in the construction was mixed generally in the proportions of 1 part cement to 3 parts gravel and 6 parts sand. The gravel was dug from the foundations and was about one-half sand and one-half gravel. The latter component varied somewhat and the proportion of cement was varied accordingly, more cement being used when the proportion of sand in the gravel increased. The concrete was machine mixed and a wet mixture used.

The three subways contained 4,833 cu. yds. of concrete, the cost per cubic yard of concrete being as follows:

	Total.	Per cu. yd.
Temporary buildings, trestles, etc.....	\$ 752	\$0.15
Machinery, pipe, etc.	416	.08
Sheet piling and boxing	1,006	.21
Excavating and pumping	1,620	.33
Arch Centers and Boxing—		
46 M. ft. at \$25.....	1,150	.24
10 M. ft. at \$13.....	130	.03
Labor in centers (carpenters at $22\frac{1}{2}$ cts.; laborers, 15 cts.)	2,250	.46
Concrete Masonry—		
Cement at \$1.83	8,861	1.83
Stone	1,788	.37
Sand and gravel (obtained from foundation)	240	.05
Drain tile	103	.02
Labor	8,091	1.63
Steel reinforcing rods, at $2\frac{1}{2}$ cts. per lb... ..	3,028	.63
Engineering, watchmen, etc.....	508	.11
Total	\$29,944	\$6.19

**Engineering-Contracting*, Oct. 17, 1906.

We are indebted to Mr. Samuel Rockwell, Chief Engineer Lake Shore & Michigan Southern Ry., for the above data.

Cost of a Dry Masonry Box Culvert.—Dry masonry box culverts have been used extensively in railroad construction, and their use will no doubt continue, especially where the haul of cement is long, as in new construction in mountainous sections of the country, also where the amount of work to be done does not justify the installation of a rock crusher. Records of cost of such work are, consequently, of value.

Among the many classes of culverts constructed, none is more lasting than a well-built dry masonry culvert. See Fig. 37. Where large stones with well defined faces can be secured, such as from rock cuttings on railroad work, these culverts can be built strong and with a very neat finish. Care should always be taken to secure good, firm bottom, and the foundation course should be placed well below the bed of the stream, and thus prevent undermining of the walls. The paving should not extend under the walls of the cul-

Fig. 37.—Masonry Culvert.

vert, for should a part of the paving become misplaced, the small paving stones will be washed from under the walls, causing the latter to cave in and ruin the culvert. The lower course of stones should be as large as can be conveniently handled, so that heavy floods, that may injure the pavement will not misplace the wall stones.

We give here the cost of a 3x3-ft. dry masonry culvert, 36 ft. long:

Excavation for foundation	20 cu. yds.
Laborers, 22 hrs. at 20 cts.....	\$ 4.40
This gives a cost of 22 cts. per cu. yd. for excavation.	

Masonry—

Mason, 60 hrs. at 40 cts.....	\$24.00
Laborers, 130 hrs. at 20 cts.....	26.00
Team and teamster, 40 hrs. at 45 cts....	18.00
Derrick, 40 hrs. at 15 cts.....	6.00

Total\$74.00

The culvert contained 50 cu. yds. at a cost of \$74, or \$1.48 per cu. yd. The stone for this culvert was taken out of a rock dump 20 ft. away. Some of the large covers had to be handled 400 ft. The derrick used was the ordinary three-leg derrick, legs 20 ft. long.

and the derrick boom was 24 ft. long, one set reaching the full length of culvert, the derrick cable being operated by horse power, pulling through block and tackle.

Cost of Concrete Culvert Pipe.*—The methods and cost of molding 4-ft. concrete culvert pipe given in the following paragraphs have been obtained from Mr. O. P. Chamberlain, Chief Engineer, Chicago & Illinois Western R. R.

During the summer of 1906 Mr. Chamberlain built a number of culverts, using a 4-ft. long concrete pipe molded in the form of

Horizontal Section.

Fig. 38.—Forms for Culvert Pipe.

hollow cylinders with square ends. They were molded with an interior diameter of 4 ft. and with 6-in. shells, giving an outside diameter of 5 ft. These pipes were laid end to end in trenches whose bottoms were cut as closely to a circle of 5 ft. diameter as could be done with pick and shovel and were covered with earth thoroughly tamped around the tops and sides. The pipes were used in low embankments, where their tops are but 18 ins. below the bottom of the ties, and thus far they have given satisfactory service under heavy freight traffic.

**Engineering-Contracting*, Feb. 13, 1907.

Figure 38 is a reproduction of the working drawings from which the forms used in the construction of these pipes were built. Both forms are of wood, of ordinary wooden tank construction. The inner form has one wedge shaped loose stave which is withdrawn after the concrete has set for about 20 hours, thus collapsing the inner form and allowing it to be removed. The outer form is built in two pieces with 2 x $\frac{3}{4}$ -in. semicircular iron hoops on the outside, the hoops having loops at the ends. The staves are fastened to the hoops by wood screws $1\frac{1}{4}$ in. long driven from the outside of the hoop. When the two sides of the outer form are in position, the loops on one side come into position just above the loops on the other side, and four $\frac{3}{4}$ -in. steel pins are inserted in the loops to hold the two sides together while the form is being filled with concrete and while the concrete is setting. After the inner form has been removed, the two pins in the same vertical line are removed and the form opened horizontally on the hinges formed by the loops and pins on the opposite side. The inner and outer forms are then ready to be set up for building another pipe.

The concrete used in manufacturing these pipes was composed of American Portland cement, limestone screenings and crushed limestone that has passed through a $\frac{3}{4}$ -in. diameter screen after everything that would pass through a $\frac{1}{2}$ -in. diameter screen had been removed. The concrete was mixed in the proportions of one part cement to three and one-half parts each of screenings and crushed stone. All work except the building of the forms was performed by common laborers. In his experimental work Mr. Chamberlain used two laborers, one of whom set the forms, and filled them and the other of whom mixed the concrete. The pipes were left in the forms till the morning of the day after molding. The two laborers removed the forms filled the day before, the first thing in the morning, and proceeded to refill them. The average time the concrete was allowed to set before the forms were removed was 16 hours. Mr. Chamberlain believes that with three men and six forms the whole six forms could be removed and refilled daily. Based on the use of only two forms with two laborers removing and refilling them each day, and on the assumption that a single set of forms costing \$40 can be used only 50 times before being replaced, Mr. Chamberlain estimates the cost of molding 4-ft. pipes as follows:

2 per cent of \$40 for forms.....	\$0.80
1.1 cu. yds. stone and screenings at \$1.85..	2.04
0.8 bbls. cement at \$2.10.....	1.68
10 hours' labor at 28 cts.....	2.80
Total per pipe	\$7.32

This gives a cost of \$1.83 per lineal foot of pipe or practically \$7 per cu. yd. of concrete. The pipe actually molded cost \$2.50 per lin. ft., or \$9.62 per cu. yd. of concrete, owing to the small scale on which the work was carried on—the laborers were not kept steadily at work.

The pipes were built under a derrick and loaded by means of the derrick upon flat cars for transportation. At the culvert site they were unloaded and put in by an ordinary section gang with no appliances other than skids to remove the pipes from the cars. As each four-foot section of this pipe weighs about two tons, it was not deemed expedient to build sections of a greater length than four feet, to be unloaded and placed by hand. On a trunk line, however, where a derrick car is available for unloading and placing the pipes, there is no reason why they should not be built in six or eight-foot sections.

Based on his estimates on the above price of \$7 per cu. yd. for concrete, Mr. Chamberlain has computed the accompanying table of comparative weights and costs of cast-iron and concrete pipes of various diameters. The cost of cast-iron pipe per pound is assumed to be 1½ cts.

TABLE XXIX.—SHOWING RELATIVE THICKNESS, WEIGHTS, AND COST OF "STANDARD" CAST-IRON PIPE AND CONCRETE.

Size and kind of pipe.	Thickness in ins.	Weight lbs. per lin. ft.	Cost per lin. ft.
12-in. cast-iron	0 33/64	75	\$1.22
12-in. concrete	2	88	0.16
18-in. cast-iron	0 47/64	187	2.72
18-in. concrete	3	220	0.36
24-in. cast-iron	1	250	4.07
24-in. concrete	4 1/4	420	0.68
30-in. cast-iron	1 1/16	334	5.43
30-in. concrete	4 3/8	602	0.88
36-in. cast-iron	1 1/8	450	7.32
36-in. concrete	4 1/2	676	1.10
42-in. cast-iron	1 1/4	600	9.75
42-in. concrete	5 1/8	960	1.55
48-in. cast-iron	1 7/16	726	11.78
48-in. concrete	6	1131	1.83

In Table XXIX. the thickness for concrete pipes of various diameters has been taken as approximately proportional to the thickness of "Standard" cast-iron pipes of the same diameter, the 4-ft. diameter pipes being used as a basis for calculation.

The first cost of concrete pipes at the place of manufacture would, according to the above table, be less than one-sixth of the cost of cast-iron pipes. The cost of transportation and of installing the pipes would, on account of the greater weight and greater number of pieces, probably be very nearly double that for cast-iron pipes.

On account of the lack of reliable data regarding this cost, Mr. Chamberlain is unable to give a fair comparative estimate of the cost of the two styles of culverts in place. However, since transportation and installation of iron pipes is but a small proportion of the cost of the completed culverts, it is evident that cost of a concrete pipe culvert in place would be but a small fraction of the cost of a cast-iron pipe culvert of the same diameter, provided the pipes were hauled only moderate distances.

Cost of Placing Cast Iron Pipe Culverts.—Mr. John C. Seamer, Engineer of Construction, C., B. & Q. Ry., gives the following data on the cost of unloading, hauling and placing cast iron pipe. In 1905 that railroad on its extension from Centralia, Ill., to Herrin, used for its culverts ordinary cast iron pipes up to a size of 48 ins. in diameter. The contract for handling the pipe was let to a contractor at 75 cts. per ton per mile for the unloading and hauling and \$2.00 per ton for placing. A careful record was kept of all labor employed in handling this pipe, and from these data the following results were obtained:

Number of tons of pipe handled.....	591
Cost per ton for unloading from flat and gondola cars.....	\$0.33
Average miles hauled	3.82
Cost of hauling per ton mile	0.44
Cost per ton mile for unloading and hauling (av. haul 3.82 miles)	0.53
Cost per ton for laying	0.55
Cost per ton in place	2.39

The greatest distance the pipe was hauled was about 10 miles. From the data obtained it was deduced that: The cost per ton for unloading the pipe is the same regardless of size; that the cost of laying pipe per ton, for pipe under 20 ins. in diameter, is about 20 per cent more than for pipe over 20 ins. in diameter. As a matter of fact it costs about twice as much per ton to lay 18-in. pipe as it does to lay 48-in. pipe.

Cost of Cast Iron Pipe Culverts.—The labor cost of pipe culverts depends almost entirely upon the amount of excavation involved. If an existing railway embankment must be cut through, obviously the labor cost will be far higher than if the pipe is laid under a trestle that is to be filled in.

For the weight of cast iron pipe, see the section on Waterworks. Also consult that section for the labor cost of handling pipe.

Mr. A. W. Merrick gives the following data of work done in 1898 on the Chicago & Northwestern. Where the embankment is more than 12 ft. high, an open trench is excavated from the toe of each slope to a point 6 ft. from the center of the track. This leaves a core 12 ft. wide under the track, through which a tunnel is dug. It is often well to insert two old stringers under the rails to keep the weight off the earth over the tunnel during construction. The trench is sheeted with vertical planks and braced. The roof of the tunnel is supported by 4-in. plank which rest on 2 x 12-in. posts whose feet stand on 3 x 12-in. mudsills running lengthwise of the tunnel. Wedges are placed between the posts and the mudsill. For a 24-in. pipe the tunnel is made 4 x 4 ft. Two planks are laid side by side in the bottom of the trench for dollies to run on, and each length of pipe is drawn in on a dolly at each end.

The cost of a 24-in. pipe culvert, 48 ft. long, in a bank 12 ft. high, was:

	Per lin. ft.
Cast-iron pipe, 250 lbs., at \$16 per ton.....	\$2.00
Labor	1.08
Total	\$3.08

The cost of a 24-in. pipe culvert, 84 ft. long, in a bank 24 ft. high, was:

	Per lin. ft.
280 lbs. cast-iron pipe, at \$14 per ton.....	\$2.00
Labor	1.73
Plank and nails.....	0.87
Total	\$3.80
End walls, \$69.....	0.80
Total	\$4.60

The detailed cost of these two end walls was:

2 cords stone, at \$3.25.....	\$ 6.50
18 footing stone, at \$0.80.....	14.40
20 coping stone, at \$0.50.....	10.00
6 sacks cement	1.37
Mason labor	\$6.85
Total	\$69.12

Mr. A. S. Markley gives the following costs in 1898 of work on the Chicago & Eastern Illinois, laborers receiving \$1.50 per day, and foremen \$2.50.

Size of pipe.	Condition.	Labor.	
		Per ton.	Per ft.
48-in.	Opening provided	\$1.25	\$0.36
36-in.	Tunneling 16 ft. bank.....	4.96	0.88
36-in.	Trench, 8 ft. bank.....	3.18	0.62
18-in.	Trench, 4½ ft. bank (7 tracks)....	1.06	0.16
16-in.	Trench, 4½ ft. bank.....	1.06	0.16

Mr. W. A. Rogers gives the following costs in 1898 on the Chicago, Milwaukee & St. Paul. It is not stated just what the conditions were, but many of the pipes were drawn through existing timber culverts and earth tamped around them. Most of the pipes were cast in 6 ft. lengths, and the price was \$14.50 per ton.

Diameter.	Material.	Labor.	Total.	Cost of each masonry end.
20 ins.	1.00	1.02	\$2.02	\$ 42
24 ins.	1.20	1.33	2.53	53
30 ins.	1.72	1.42	3.14	66
36 ins.	2.45	1.64	4.09	78
42 ins.	3.25	1.98	5.23	90
48 ins.	4.30	2.36	6.66	100

No pipe smaller than 20 ins. is used, for this is the limiting size that a man can crawl through when it is necessary to clean a pipe out. Larger sizes than 48 ins. have caused trouble by breaking. Pipes were put in by the track department.

Mr. Geo. J. Bishop gives the following cost in 1898 of work on the Chicago, Rock Island & Pacific. The pipes were all laid under trestles that were to be filled in. Hence the labor cost was lower

than in the preceding cases. The price of pipe was \$15.80 per ton. The following is the cost per lineal foot.

Diameter.	Weight per ft. lbs.	Pipe.	Labor.	Total.
20 ins.	211	\$1.67	\$0.09	\$1.73
24 ins.	222	1.92	0.17	2.09
30 ins.	267	2.30	0.22	2.52
36 ins.	467	3.49	0.42	4.11
42 ins.	634	5.00	0.70	5.70
48 ins.	797	6.29	0.72	7.01
60 ins.	1,263	10.61	1.26	11.87

In the R. R. Gazette, Vol. 19, p. 122, cast iron culverts made in quadrants bolted together are described. The quadrants are provided with outside flanges, and with a recess in which tarred rope smeared with neat cement is placed before bolting together. No skilled labor is required. A 7-ft. culvert, 50 ft. long, contained 45 short tons of cast iron. The labor of unloading it from the cars was \$17.50, or 40 cts. per ton, and the labor of putting it in place was \$150, or \$3.20 per ton.

Corrugated Metal Culvert.—The metal culvert was 18 ft. long and 4 ft. in diameter, the bottom being 8 ins. lower than the grade line of the ditch. Concrete solid walls were built rising from bottom of culvert to the ground surface, and extending into both banks. These walls were 20 ins. thick to top of pipe, 18 ins. thick to within 8 ins. of the surface, and the top 8 ins. was 12 ins. thick. The top 8 ins. was of 1:6 mortar and the remainder was of 1:4:4 broken tile concrete. Condemned tile was broken into 1 to 2-in. pieces. The walls were 12 ft. long at the level of the top of the pipe and 20 ft. long at the surface. The forms were constructed by first placing the plank parallel to the slopes until the concrete was carried to the top of the pipe, and up the slopes to the surface. After this had hardened for 24 hours, the planking was taken down and laid horizontal to construct the center part of the wall. This method of constructing the forms required a minimum of lumber and no cutting of the lumber. The cost of the culvert was as follows:

1 corrugated metal pipe, 4 ft. diam., 18 ins. long, \$6 per ft.	\$108.00
Hauling culvert from depot, 2 men and team, 2 hrs. at 65c per hr.	1.30
Labor, preparing ditch for culvert, 2 men 3.5 hrs. ea. at 30c	1.40
Bolting pipe together and lowering into ditch, 3 men, 3.5 hrs. at 20c.	3.10
37.5 sacks of cement at 75c per sack.	28.12
6.6 cu. yds. of sand at \$1.50 per cu. yd.	9.90
5 cu. yds. broken tile at 54c per cu. yd. for breaking.	2.70
Labor of building abutment, 82 hrs. at 20c per hr.	16.40
2 men and team grading, 5 hrs. at 65c per hr.	3.25
Incidentals	3.00
Total	\$175.64

Cost of Tearing Down a Small Bridge.—A small highway bridge of 35-ft. span, and roadway 25 ft. wide, contained 10 tons of iron in the trusses and 4,650 ft. B. M. in the flooring. The flooring was 8-in. oak plank on 3 x 12-in. stringers spaced 2 ft. apart, and two

8 x 14-in. stringers under an electric car track. It took 8 men and 1 foreman 3 days to tear down and store the bridge, at a cost of \$26.

A wooden footbridge, 6 ft. wide and 100 ft. long over a creek, contained 4,000 ft. B. M. It took 8 men and a team 3 hrs. to tear down and remove this structure, which was essentially a light temporary trestle floored with 3-in. plank. The cost was \$1 per M for this tearing down. The same gang had originally erected this structure at a cost of \$2.75 per M.

Cost of Moving a 65-ft. Bridge and New Abutments.—A steel highway pony truss bridge of 65-ft. span and 14-ft. roadway had been erected upon timber pile abutments that had rotted badly. New abutments were built adjoining the old abutments, by driving 12 iron piles for each abutment and its wing walls. These piles were of old steel rails 30 ft. long, and were driven 20 ft. deep. A small pile driver operated by 5 men and 1 horse averaged 3 piles per 10-hr. day, for 3 days. Then 1 day was spent in building a falsework, and 2 more days raising and shifting the bridge from its old abutments to the new. The cost of pile driving was \$20, or \$1.25 per pile. The cost of building the falsework was \$10, and the cost of moving the bridge was \$20.

SECTION XIII.

STEEL AND IRON CONSTRUCTION.

Need of More Printed Data.—Notwithstanding that this has been called the Age of Steel, there have been fewer articles printed on the cost of steel work than on any other class of engineering construction. We have had books without number on the design of steel bridges, but next to nothing in those books on the itemized cost of steel bridges. Indeed, aside from the articles on the cost of steel bridge erection published in *Engineering-Contracting* within the last four years, practically nothing on this important subject has ever appeared in the engineering journals. In the section on Bridges will be found the data just referred to. For some time to come, too much cannot be published on the methods and cost of steel construction of all kinds.

Cross-References.—To avoid duplication, it seems advisable not to give in this section any of the data on steel and iron work given in other sections of the book, but rather to provide a very complete index of Steel Construction and another of Iron Work. Such an index will be found in the back of this book.

As an indication of what will be found on steel and iron in the various sections, it may be well to bear in mind the following facts: (1) The cost of shaping and placing steel for reinforced concrete is given in the sections on Concrete, on Sewers, on Bridges, on Buildings, etc.; (2) the cost of laying cast iron and steel waterpipe, the erecting of steel standpipes, etc., will be found in the section on Waterworks; (3) the cost of building steel bridges and viaducts, iron and steel culverts, etc., will be found in the section on Bridges; (4) the cost of laying steel rails will be found in the section on Railways; (5) the cost of putting on expanded metal lath, galvanized iron siding, tin roofing, etc., will be found in section on Buildings.

As above stated, use the index under Steel Construction and under Iron Work.

Cost of Pneumatic Riveting.—Mr. A. B. Manning gives the following data:

One 12 hp. gasoline driven air compressor (Fairbanks, Morse & Co.); two galvanized iron water tanks; one galvanized iron gasoline tank; one large main reservoir; one small auxiliary reservoir; hose and fittings; cost mounted on car \$1,073. Operating at 90 lbs. pressure this compressor furnished air for 2 pneumatic hammers, 2 drills, 2 rivet forges, and 1 blacksmith forge, all working at one

time. The 3 hammers and the 2 drills cost (in 1899) \$637. The cost of repairs for 16 months averaged \$3 per month on this \$1,700 plant. The cost of operating was as follows per day:

15 gals. gasoline, at 11.2 cts.....	\$1.68
Oil, waste, etc.....	0.12
Depreciation (estimated on 30% basis, for 312 days)	1.09
Repairs	0.11
Total per day.....	\$3.00

On the basis of running 3 rivet hammers, this is \$1 per hammer for power.

Power for one hammer per day.....	\$1.00
Oil for one hammer per day.....	0.12
2 men driving rivets, at \$2.40.....	4.80
1 man heating rivets.....	2.30
Total for one hammer per day.....	\$8.12

A pneumatic riveter on bridge work averages 500 rivets per 10-hr. day for \$8.12, or \$1.62 per hundred rivets. On one day 700 rivets were driven, by using an additional man to take out fitting-up bolts, etc. The above costs are based upon the erection of 22 bridge spans, aggregating 2,455 lin. ft. and 80,065 rivets.

The cost of riveting by hand is as follows:

2 men, at \$2.40.....	\$4.80
2 men, at \$2.20.....	4.40
Total per gang per day.....	\$9.20

Such a gang averages 250 rivets per day, which is equivalent to \$3.68 per hundred rivets.

Mr. F. S. Edinger states that with a 12 hp. gasoline driven compressor and an 80 cu. ft. air receiver, five longstroke hammers were operated at one time without reducing the air pressure below 75 lbs. The five hammers when driving 50 rivets ($\frac{1}{2}$ -in. diam.) per minute are using air only about 5% of the time. The same compressor will run 2 hammers and 2 drills at one time. The drills use more air than the hammers as they run uninterruptedly. The drills can be used for boring timber by inserting an auger in place of a drill; but the speed is not high enough for wood boring. Two men and a heater form a riveting gang and they drive twice as many rivets as three men and a heater drive by hand. The cost of fitting up and riveting on new steel bridges (all rivets $\frac{1}{2}$ -in.) was 35 to 40% less than if the work had been done by hand, and the work was done better.

Pneumatic and Hand Riveting.—Mr. Charles Evan Fowler gives the following. On the Northwestern Elevated Ry. construction, Chicago, percussion riveters were used, driving as high as 500 rivets per day, with three men at the riveter and a heater. Hand gangs on that work averaged 300 rivets.

In reinforcing the Manhattan Elevated, N. Y., the record is 465 to 525 rivets per day with percussion machines, and careful tests showed that it required 5 cu. ft. of free air per $\frac{1}{2}$ -in. rivet.

On the Boston Elevated Ry., in 1900, the long gun type of Boyer riveters were used. Owing to the cramped condition of much of the work, only 300 rivets per day were driven, two men at a riveter and a heater at the forge. Hand gangs drove as many as 400 rivets per gang per day.

Cost of Erecting Steel in N. Y. Subway.—The cost of erecting the steel posts and girders in the N. Y. subway was as follows on one section where 4,800 tons were erected:

	Per ton.
Labor trucking.....	\$ 1.47
Labor placing and riveting.....	11.68
Labor painting.....	0.90
Materials for painting.....	0.70
Materials for placing and riveting.....	0.90
Power	0.30
Total	\$15.95

Iron workers were paid \$4 for 8 hrs.; iron foremen, \$5; painters, \$2. There was 1 foreman to every 10 men.

The contract price for erecting and painting was \$13 a ton, so that money was lost by the contractor on this work. The men worked under difficulties, and with little energy.

Weight of The Eiffel Tower.—The Eiffel Tower weighs 7,500 tons. It is 906 ft. high, 33 ft. square on top, and 330 ft. square at the base. The power plant is 500 hp.

Cost of a Gas Pipe Hand Railing.—A gas pipe hand railing for a small stone-arch bridge was made of three lines of 1½-in. pipe rails and posts. The weight of the pipe was 800 lbs. for 100 lin. ft. of railing (50 ft. on each side of the bridge). The cost was as follows:

100 lin. ft. of railing ready to erect.....	\$65.00
Hauling 1¼ miles.....	0.69
1 qt. asphaltum paint.....	0.20
Paint brush.....	0.20
9 lbs. sulphur, at 8 cts.....	0.72
Iron kettle to melt sulphur in.....	0.40
Labor erecting railing, 17 hrs., at \$5 cts.....	5.95
Labor erecting railing, 2 hrs., at 15 cts.....	0.30
Total for 100 ft. of railing.....	\$73.37

The principal cost of erecting was the drilling of 48 bolt holes (½ x 2 in.) in the stone coping. The bolts that passed through the cast-iron post bases were held with sulphur. The posts were made of 1½-in. gas pipe, crosses and tees. The 1½-in. pipe measured about 2 in. outside diameter, which is a good size for hand railing.

On another job 100 lin. ft. of hand railing were built along an embankment. The railing was made of 3 lines of ¾-in. gas pipe (1-in. diam. outside) made as above described, except that each post was fastened to an oak plank buried in the ground, and an

guys and 4 sets of $\frac{3}{4}$ -in. blocks for hauling in guys, and bracing the stack inside was \$260. A gang of 8 men at \$1.30 per day and one top man at \$2.25 per day were employed, with some extra men for about 2 hours.

The erection as described was planned and carried out by Mr. George B. Nicholson, a hoisting engineer. Incidentally it may be stated that Mr. Nicholson undertook the job after it had been rejected as impossible by expert riggers. We consider this a rather remarkable job of hoisting engineering. Only one man, Mr. Nicholson, was a skilled man, all the others being ordinary laborers with no experience in hoisting and rigging. In addition the method of rigging the tackle, using only one line to run through three sets of blocks on the stack and one block on the mast, is notable. We are indebted for the information from which this description has been prepared to F. W. Raymond.

Cost of Cast-Iron Work.*—The total weight of the cast-iron stairway trim, manhole covers, etc., in the U. S. Government Printing Office at Washington, D. C., was 20 tons. The total value in place was \$221.25 per ton. The cost of erection was \$62.50 per ton, which is an enormously high labor cost, attributable to the fact that the work was done by Government forces.

The wages paid per eight-hour day were as follows:

Superintendent	\$5.25
Foremen	4.25
Ironworkers	3.45
Helpers	1.60
Smith	2.25

The total weight of the cast-iron frames and baseboard in the building was 743.4 tons of the total contract amounting to \$107,800 or \$145 per ton. The cost of erection was practically \$23 per ton.

Cost of Shop Drawings for Steel Work.†—Mr. R. H. Gage gives the following:

The data were gathered by the writer while in charge of the Drafting Department of A. Bolter's Sons' Structural Steel and Iron Works, of Chicago, Ill., during the years 1904, 1905 and 1906.

The works are divided into three different departments, the Structural Shop, the Architectural Shop and the Foundry. The Structural Shop has a capacity of 800 tons per month. The Drafting Department employs on an average seven or eight engineers. All the work is standardized with regard to details to as great an extent as possible, in order to decrease the work in the Drafting Room, yet not to such an extent that it would be difficult for the shop men to read the drawings. For example, all beam, steel and cast iron column connections, with the exception of special cases, are not drawn and dimensioned completely, but merely indicated. The shop and drafting room have been provided with a set of the

**Engineering-Contracting*, Mar. 18, 1908.

†*Engineering-Contracting*, Aug. 23, 1907.

firm's standards, which have all these connections drawn out completely with dimensions and which give lists of the material.

The data here presented were taken from a great variety of work, such as public and private school buildings, churches, breweries, malt houses and elevators, grain bins, warehouses, libraries, hospitals, apartment buildings, factories and manufacturing plants, train sheds, mill buildings, office buildings, electric lighting plants and pumping stations.

Table I shows the character of the buildings and also the average cost of preparing the drawings. The cost of drafting material and blue prints is not included. Where the material for the work is to be ordered from the mill and not taken from stock, the cutting bills or mill orders are taken as being part of the details. Table II (not reproduced here) shows the particulars of the buildings from which the data in Table I were derived.

TABLE I.—COST OF SHOP DRAWINGS.

Type.	Character of Building:	Av. cost per ton.
1.	Entire skeleton construction, i. e., loads all carried to the foundation by means of steel columns.....	\$1.45
2.	Interior portion supported on steel columns; exterior walls carry floor loads and their own weight.....	1.22
3.	Interior portion carried on cast iron columns; exterior walls support floor loads as well as their own weight.....	0.70
4.	No columns and floor beams resting on masonry walls throughout.....	0.85
5.	Structure consisting mostly of roof trusses resting on columns.....	2.47
6.	Structure consisting mostly of roof trusses resting on masonry walls.....	1.25
7.	Mill buildings.....	2.56
8.	Flat one-story shop or manufacturing buildings.....	0.74
9.	Tipples, mining structures or other complicated structures..	4.38
10.	Malt or grain bins and hoppers.....	2.47
11.	Remodeling and additions where measurements are necessary before details can be made.....	1.87

There is always a noticeable decrease in the cost of details when the plans for the iron work are made and designed by an engineer and separated from the general plans. On comparing the cost of picking out the structural steel and making the shop drawings from the architect's plans and the engineer's plans, it was found that the cost of the former is on an average of 35% higher than the latter. Where the engineer's plans are made with no dimensions, with only the outline and sections given, it being necessary to refer to the general plans for the location and dimensions, there is no saving of time, and the detailing runs as high as on the architect's plans.

Inaccurate plans, where the draftsman is continually finding errors, cause an increase in the cost, as it is necessary to wait and refer the matter to the architect; and in most cases he, in turn, has to check over his plans before he can settle the question, all of which causes considerable delay and takes time that might otherwise be spent in making the drawings.

The cost of structural steel details depends on so many things that it is hard to set any fixed rule for determining what this cost is. The type of the building is the first consideration; then the architect and engineer, their methods of drawing up their plans; and finally the detailing drafting force one is obliged to depend upon.

Cost of Sheeting a Foundation Pit with Steel Sheet Piling.¹—The old U. S. Custom House on Wall St. in New York City was reconstructed in 1908 for the use of the National City Bank. The old building was four stories high with heavy stone walls founded on spread footings. In addition there were on the front 14 heavy stone columns, 12 in a row across the front and 4 inside the entrance. The plans for reconstruction involved the removal and renewal of everything inside the main walls which were to be preserved. The new interior was planned to be of steel frame construction, the foundations for which would be some 7 ft. to 12 ft. below the level of the footings of the old walls and columns.

The problem to be solved was the construction of the new and deeper foundations without undermining the old footings or causing any settlement which would crack or otherwise injure the structure supported by these footings. The soil was a mixture of clay and sand containing many 10 and 12-in. stones. It also carried considerable water. Obviously careful precautions were under the conditions necessary. The plans adopted were to drive a row of Wemlinger steel sheeting all around the interior of the building about 12 in. from the edges of the footings and with its top left about 12 in. higher.

The sheeting used was the Wemlinger corrugated double, consisting when driven of two thicknesses of 3/16-in. steel sheets; each sheet was 24 in. wide and 14 ft. long. The two sheets were driven together, thus sheeting a width of 34 in. each driving. The driving was done in two steps or moves. The first step was to a depth of 2 ft. and was made with an Ingersoll-Rand Type D sheet pile driver. The remaining depth of about 11 ft. was secured with a Vulcan No. 2 steam hammer having a 2,000-lb. ram. A steel plate was placed over the pile and on it was set a 2-in. steel block which took the blow of the ram.

The mounting of the drivers was novel. A 1 1/4-in. steel cable was stretched horizontally along the inside of the old wall and from it were suspended the two hammers and a light tackle for handling the sheeting. The lighter hamper was suspended on a differential hoist. The Vulcan hammer was suspended from a block operated by a crab so mounted that the mounting formed a guide and prevented the swing of the hammer. The maximum span of suspending cable used was 190 ft.

Inside the driven sheeting there was built a wall of concrete. Pockets or sections about 10 ft. wide were excavated so as to lay bare the sheeting at regular intervals and have a supporting core between each pair of sections. As soon as the excavation of each

¹Engineering-Contracting, Oct. 12, 1909.

pocket had been carried down about 8 ft. a 12 x 12-in. waling timber was set against the sheeting and braced back to the rear and bottom of the pocket. The excavation was then carried down to a depth of 8 or 9 ft. and a wall or block of concrete was deposited in the pocket against the piling. After this concrete had set the cores between pockets were excavated and in turn filled with concrete. This completed a concrete wall 5 ft. thick entirely around the sheeting inside. The remaining excavation went on inside this wall and was accomplished with absolutely no disturbance of the old masonry walls and footings.

The contractors for the sheeting were the Wemlinger Steel Piling Co. of New York, N. Y. The cost of the work to the contractors was as follows:

Rental of Plant:

Boiler at \$3 per 8-hr. day.....	\$ 134.37
1 Ingersoll-Rand hammer at \$1.50 per day } ..	264.36
1 Vulcan hammer at \$6 per day	
Total rental.....	\$ 290.73
Repairs to plant.....	184.18
Permanent plant.....	319.09
Coal at \$5.76 per net ton.....	80.62
Supplies	22.64

Labor:

Driving	
House shorers at \$3.50 }	\$1,089.82
Foreman at \$4.50	
Unloading piling laborers at \$2.25.....	32.00
Steam	
1 engineman at \$4.50 }	112.91
1 fireman at \$2.25	
Constructing and erecting plant.....	65.56
Total labor.....	\$1,299.79

Freight and Haulage:

Freight	\$ 334.01
Hauling 105 tons of sheeting.....	179.76
Hauling supplies and equipment.....	38.16
Total	\$ 551.93
Liability insurance.....	50.77
Grand total.....	\$2,899.65

The amount of sheeting driven was 638 lin. ft., 14 ft. long, or 8,932 sq. ft. Including the cost of the sheeting not given above, the cost was \$0.885 per sq. ft. Exclusive of freight and hauling charges on sheeting, \$513.77, which may be charged to the cost of sheeting ready for driving, the cost of driving was \$2,385.88, or \$0.267 per sq. ft. The labor cost of driving was \$0.146 per sq. ft.

In further comment on these costs the Wemlinger Steel Piling Co., which furnishes them to us, writes as follows:

"You will note that the cost of doing this work was somewhat high which, in the first place, is explained by the fact that we had

to employ union labor at high wages. Furthermore the expense for rental and repairs of equipment were higher than they would have been if we had been regularly equipped for doing this class of work. This was, however, a contract which we took mainly for the purpose of introducing and demonstrating our material. You will note that we have charged the entire cost of the permanent plant against this contract, the reason for this being that most of the plant was purchased especially for this work. Another reason for the high cost is our own comparative inexperience and that all the labor employed, which in spite of the fact that members of the House Shorers' Union were employed, proved rather ineffective. We believe that considering the experience we have now we could easily do the same work for at least 25% less cost."

Cost of Driving Steel Sheet Piling for Cut-off Wall of a Dam.*—Mr. Carl P. Abbott is author of the following:

The construction of a concrete dam, with tide gates, to replace an old wooden dam on a salt marsh was completed in the summer of 1906 by the Queens County Water Co., of Far Rockaway, N. Y. In planning the new work considerable thought was given to the kind of sheet piling that would best answer the purpose of keeping the water from getting underneath the dam and the choice was made of steel sheet piling of the form manufactured by the United States Steel Piling Co., of Chicago, Ill. Besides supplying the requisite water-tight wall, this piling seemed likely to be more durable and more surely driven and certain to add considerably to the strength of the structure.

The piling was driven lengthwise of the dam and in the center, and, as a turf dike was carried from each end of the concrete dam to shore, the piling was carried five lengths beyond the concrete to form a sort of bond at the junction of concrete and turf. There were two lengths of piling used, 25-ft. and 18-ft.; the 25-ft. lengths at each end of the dam and one length between each gate, and the 18-ft. lengths under the gates. The 25-ft. lengths were driven flush with the surface of the marsh, so the 18-ft. lengths were driven flush and then the pile-driver was moved back over the line and the 18-ft. lengths run down 7 ft. further with a 16-ft. piece used as a runner by bolting a couple of wrought-iron plates on the lower end to hold it on the pile. A half-round pine filling strip was used. The material encountered was about 8 ft. of turf, then 3 or 4 ft. of sand, then a streak of hard pan and then sand again, and where the driving cap was used the piles were not battered at all. Some bids were put in for the driving, but as they looked pretty high we decided to do the work ourselves.

We took an old wall drilling machine, and with very little carpenter work it made a good pile-driver. A 1,500-lb. hammer was used and a driving cap made by the United States Steel Piling Co. was also used for most of the work.

The driving gang usually consisted of three men, who were taken from the company's force and were very quickly broken in, with

**Engineering-Contracting*, Jan. 16, 1907.

some extra men for a part of the time to haul the piles across the channel from the railway track and to move the machine to the job. The cost of driving given below includes hauling the piles over and moving the machine to the job. The cost of moving the machine away was not included, as the machine and boiler were used for other purposes for some time after.

The cost of labor, supplies, etc., was as follows:

20	days' labor at \$2.25.....	\$ 45.00
9 1/2	days' labor at \$2.10.....	19.95
8 1/2	days' labor at \$2.00.....	17.00
2	days' labor at \$1.75.....	3.50
24	days' labor at \$1.50.....	51.00
Total labor cost.....		\$136.45
17	days' use of machine at \$2.00.....	34.00
2	tons coal at \$5.00.....	10.00
Superintendence at 5 per cent.....		9.00
Total machinery and supplies.....		\$ 53.00
Grand total.....		\$189.45

There were 55 piles each driven 25 ft., making a total of 1,375 lin. ft. driven at a cost of 13.8 cts. per ft. for the driving. As the men were inexperienced it cost more to drive the first few piles than afterward, and if the same number were to be driven again the cost of driving would be very much decreased. As a whole, the steel piling was very satisfactory and easy to handle and drive, even by men not accustomed to that sort of work.

Cost of Steel Sheet Piling for Cofferdam.*—The cost of 140 steel sheet piles in place was as follows. The piles were 26 ft. long, driven to an average penetration of 22 ft.

The work was done by the U. S. Reclamation Service.

The type of piling is that manufactured by the Carnegie Steel Company for the United States Steel Piling Co., of Chicago. The piling cost at the factory is 70 cts. per lin. ft., and as its weight is 35 lbs. per running foot, the cost therefore was 2 cts. per lb. The freight rate from the factory at Pittsburg to Whalen, Wyo., was \$1 per 100 lbs., thus making the total cost f. o. b. cars at Whalen, about \$1.05 per lin. ft.

The line of piles under consideration was driven in August, 1907, and forms a part of the south side of the cofferdam used in the construction of the concrete diversion dam on the North Platte River, at the head of the Interstate canal. None of the piles were driven under water, and the material into which they penetrated consists of sand and coarse gravel. The piles were dragged from the railroad siding to the river bank, and carried across the river on ~~skids~~.

The pile-driver outfit used was a Lidgerwood single drum 20-hp. hoisting engine and a 2,800-lb. hammer, having an average drop of 8 ft. When no hindrance occurred by accidents to the machinery, the average number of piles driven per twelve hours was 27, with an exceptionally high run on August 9 of 29.

**Engineering-Contracting*, June 10, 1908.

The regular pile-driving crew consisted of one foreman, one engineer and four laborers. Each of these men received 25 cts. an hour for his work except in transporting the piles from the railroad station to the driver, in which case the laborers were paid for at the rate of 25 cts. an hour and teams at the rate of 20 cts. per hour. The total labor cost of unloading and moving the piles from the railroad to the driver was \$53.25, making a unit cost per linear foot of pile of \$0.015. The total labor cost for driving was \$190.06, making a unit cost of \$0.052 per linear foot of pile.

Below are tabulated the total and unit costs of the piles in place distributed under the headings of plant depreciation, labor, materials and supplies. The depreciation on the engine was about 2% of its original cost, while that on the driver was about 30% of its original cost, including repairs made on it. The charge for materials contains in addition to the piling and freight thereon, \$12 worth of wood fillers used in connection with the piling. The charges under supplies consist of coal and oil for the engine and labor for carrying drinking water. Six tons of coal were used, at \$5.50 per ton.

Distribution of costs.	Total cost.	Unit cost per pile.	Unit cost per foot of pile.	Unit cost per foot of penetration.
Plant depreciation.	\$0.00	\$ 0.416	\$0.014	\$0.019
Labor	242.30	1.742	0.067	0.079
Materials	3,350.00	27.508	1.058	1.250
Supplies	44.18	0.312	0.012	0.014
Total	\$4,197.48	\$29.978	\$1.153	\$1.362

Cost of Driving Some Steel Sheet Piling.*—The work for which the costs are given consisted of the construction of cofferdams preliminary to building the substructure of a double track bridge for the Norfolk & Western Ry. at Chillicothe, O., the work being necessitated by a change of line at that point.

The cofferdams were built of the steel piling manufactured by the U. S. Steel Piling Co., of Chicago, the same piling being reused for the three piers. The cofferdam was 16 ft. x 62 ft., and 156 pieces of piling, 16 ft. in length, were used. The piling was driven to a depth of 14 ft. below water level, the water being from 3 ft. to 6 ft. deep. The material into which the piles were driven consisted of coarse gravel ranging in size from $\frac{1}{4}$ in. to 2 ins. in diameter.

In driving the piling for the first cofferdam, the piling was picked up from the shore by means of a steam derrick and put into place for the pile-driver. An ordinary drop-hammer pile-driver, rigged on a scow, and having a 2,000-lb. hammer, was used.

The piling in the first cofferdam was driven in three days, the crew and their wages per 10-hr. day being as follows:

Foreman	\$ 5.00
Engineer on derrick.....	3.00
Tagman	2.00
Engineer on pile driver.....	3.00
Six men handling pile driver and boat.....	10.50
Total	\$23.50

*Engineering-Contracting, June 6, 1906.

The total cost of driving the 156 pieces of piling was \$70.50, or 45.2 cts. per piece.

The same crew constructed the next cofferdam, five days, however, being consumed in the work. The main reason for the difference of time was in the facilities for handling the piling. In this cofferdam the piling was picked off the shore by the derrick, placed on the scow on which the pile-driver was rigged, and then taken to the site of the cofferdam, where it was placed in position by the driver instead of by the derrick as in the first case. The cost of driving the piling for this cofferdam was \$117.50.

The above figures do not take into account fuel and plant rental, nor the cost of braces and waling which were used as described below.

In order to make the cofferdam ready for pumping out a 6-in. x 8-in. waling piece was bolted to the inside of the sheet piling and braces placed across from side to side at intervals. From three to five braces were used along the top, but were used at no other point.

We are indebted to Mr. L. E. Sturm, Railroad Contractor, of Columbus, O., for the information in the above article and for the illustrations.

Cost of Steel Sheet Piling in a Cofferdam and in Caissons.*—As it is only within the last few years that steel sheet piling has come into general use, the experience of the William P. Carmichael Co., Engineers and Contractors, of Williamsport, Ind., with this form of piling will be of interest to our readers. About a year ago this firm purchased enough sheet steel piling to construct a cofferdam of a total perimeter of 132 ft. and a depth of 12½ ft. This was first used in the construction of a pier foundation for the Wabash R. R., in the Huron River, near Detroit, Mich. The water at the point where the pier was to be constructed was from 5 to 8 ft. deep. The bottom consisted of from 2 to 3 ft. of alluvium, on top of a blue sandy clay, partaking in a measure of the nature of quicksand. This being the company's first experience with steel sheet piling, they attempted to assemble the units and complete the box before driving. This was finally done, but at the expense of a good deal of unnecessary labor and time. At first it was proposed to drive six pieces at once by striking a cap covering that many piles, but it was soon found that a pretty stiff blow from a 2,600-lb. hammer was required to drive two at a time. The piles were driven to a depth of 3 ft. below the proposed bottom of concrete.

After the piles were driven to the required depth, an attempt was made to pump out the water from the caisson. A 6-in. centrifugal pump was used, but failed to lower the water level more than a few inches. An outer row of 2-in. wooden sheet piling was then driven about 6 ft. from the steel box, and the space filled with clay and puddled. This served its purpose, for with the exception of a few

**Engineering-Contracting*, May 9, 1906.

leaks, very little water came into the caisson. An attempt was made to stop these leaks with clay, but owing to the presence of sand in the clay, the attempt was only partially successful.

The piles were withdrawn in practically as good condition as when driven, so that the cost of material was only charged at 2% on account of the foundation. After the first piece was loosened, the piles in the foundation were withdrawn at a very small cost. Owing to an accident to the foreman, no accurate cost account was kept of this work.

The next use of the steel piling by this firm was in caissons for four piers for a highway bridge across the Wabash River; for this

Fig. 2.—Driving Steel Piling.

work some excellent cost data are given further on. Three of these piers were upon an island. At the time the work was done these sites were not covered by water. The piles were driven into coarse sand and gravel. The plant used for the work consisted of a small land pile-driver, having derrick and steam hoist for handling the hammer, which weighed 2,000 lbs. A steel bound wood driving head was fitted between leads and was used to protect the head of the piles in driving. An illustration of the plant is given in Fig. 3.

In pulling the piling, it was often necessary to use a pulling lever with a 4 to 1 purchase, the derrick and hoist being hitched to lever. On this job strips of wooden batten were used in the batten or the groove between each two steel piles, and in this way the cofferdam was made practically watertight. So much so, indeed, that

an ordinary diaphragm pump would have handled all the water except for what came up from the bottom of the pit.

The piling was found to be in good condition after being pulled, only two pieces being in bad shape. And those could be fixed up by an ordinary blacksmith at a cost not exceeding one-half of the value of the pieces.

Now as to the cost of driving and pulling the piling. Below is given the cost record on the third pier. Work on this was begun Oct. 6, 1905, and completed Oct. 11. The gang and rig worked a total of 55 hours and finished driving the piling in 4½ days. Some days, however, the gang worked for 15 hours, as is shown in the labor cost below. The wages of laborers were from 17½ cts. to 20 cts. per hour, depending upon proficiency and length of service. The enginemen and derrickmen received 22½ cts. per hour, and the foreman on the job for which the data below are given was paid 25 cts. per hour. The low rate of wages paid to the foreman was due to the fact that he was a new man in that position and did not have to assume much responsibility, Mr. M. C. Andrews, of the contracting firm, being in charge of the work in person.

The cost of driving and pulling was as follows:

Driving:	
Labor	\$ 93.00
Use of machinery, fuel, etc., 5 days.....	15.00
Total for driving	\$108.00
Pulling:	
Labor	\$ 50.00
Use of machinery, fuel, etc., 8 days.....	10.00
Total for pulling.....	\$ 60.00

As 130 piles were each driven 11½ ft., or a total of 1,495 ft., the cost per foot of pile for driving was 7.2 cts.; the cost per foot of pile for pulling was 4 cts., making the total cost for driving and pulling 11.2 cts. As is shown in the table below this 11.2 cts. also includes the cost of straightening bent and warped piles. The labor cost of driving the piles can be further summarized and in the tabulation below is given the rate of wages and the hours worked each day by the various classes of labor.

Rate.	Labor Cost.	Driving.	Straightening piles.
Oct. 6.....	\$13.54	\$13.54
Oct. 7.....	28.92	21.00	7.92
Oct. 9.....	17.70	14.00	3.70
Oct. 10.....	22.17	23.17
Oct. 11.....	10.68	10.68
Totals	\$93.01	\$81.39	\$11.62

The work accomplished each day was as follows: Oct. 6, drove 21 piles and worked straightening bent piles; Oct. 7, drove 25 piles and finished straightening bent piles; Oct. 9, drove 30 piles; Oct. 10, drove 35 piles; Oct. 11, drove 19 piles.

In conclusion we would call especial attention to the illustration showing the pile-driving plant. It will be noted that the hammer

was suspended from the boom of a derrick, and that the engine used to operate the derrick was also used to drive the piles. The hammer is shown outside the leads of the pile-driver, but, in driving, it is placed between the leads. In fact, the same engine operated the derrick, shifted the driver from place to place, placed the pile in position and handled the hammer. The fall was not usually greater than 20 ft., and consequently very little damage was done to the derrick.

The steel piling used on the above work was made by the United States Steel Piling Co., of Chicago, Ill. We are indebted to the William P. Carmichael Co. for the information given in this article.

Cutting Off Steel Sheet Piles with the Electric Arc.*—In the interesting paper on steel sheet piling by Mr. Wm. A. Fargo, which was published in our issue of May 1, 1907, some data were given of the use of the electric arc in cutting off steel piles at the New Hoffman House foundation work in New York City. Since the publication of this article we have received from Mr. Frank C. Perkins, Electrical Engineer, of Buffalo, N. Y., a photograph of the work in progress, together with a brief account of the apparatus employed.

The steel piles being cut are $\frac{5}{8}$ in. thick in the web and 3 ins. at the interlocking points. It is stated that the time required in burning the $\frac{5}{8}$ -in. steel is four minutes per foot and the time taken at the interlocking points is said to be 3 minutes.

The arc light carbon is held in a metal clamp fastened to a metallic rod and socket, which is in turn bolted to a long wooden pole, the cable conducting the current being flexible and connected to the metal clamp of the carbon terminal. The steel to be cut is connected to the other conductor from the alternating current circuit. As shown in the illustration the men are protected from the extreme heat and terrific glare by goggles and asbestos masks as well as gloves, as it has been found that the carbon fumes produced by the high power electric arc, affected the lips and other parts of the face and hands.

About 1,200 amperes are being utilized at 50 volts pressure, alternating current being employed stepped down to the above voltage from the high pressure service of 2,500 volts. Single phase alternating current is employed, taken from the street service mains, the frequency being 60 cycles per second.

Referring to this work Mr. Fargo, in his paper says: "The cost of cutting steel piling with current at 10 cts. per kw. and the attendant at 50 cts. per hour, is stated to be as follows per foot of piling cut:

Cost of current.....	\$2.86
Labor	0.40
Total	\$3.26

*Engineering-Contracting, June 26, 1907.

This is rather high, and the hack-saw would probably be cheaper. However, with current at say 3 cts. per kw.-hour the cost per foot would be but \$1.17. Even at this rate, with labor competent to use a hack-saw at 25 cts. per hour, the saw would be the cheaper."

Cost of Driving Steel Sheet Piling.*—A valuable record of experience in driving steel sheet piling in hard soils was given recently by Mr. Wm. A. Fargo, Civil and Hydraulic Engineer, of Jackson, Mich., in a paper read before the Michigan Engineering Society. Through the kindness of Mr. Fargo we have received some additional cost data on steel sheet piling work, and these, with the original paper, are printed in the following paragraphs:

Steel sheet piling is used for purposes entirely similar to wood sheet piling, but is much more certain in results obtained. The principal applications of steel sheet piling are as follows: (1) **Cofferdams:** For building and structure foundations, including bridge piers and abutments. Also for mine shafts where the piling may be forced down in the manner of a caisson or shield. (2) **Dams:** For the dam itself, as for low dams; thus requiring no other cofferdam or pumping out of the foundation pit. As a cut-off across a valley under a dam or beneath a core wall. As a permanent enclosing wall down to an impervious stratum for the masonry structure of the dam, or for power house or other building not necessarily part of a dam; or as a downstream toe protection only. (3) **Retaining Wall:** Temporary or permanent as required in building footings close to an existing structure. This use is essentially similar to the cofferdam.

The types or varieties of steel sheet piling are as follows: (1) **Special rolled sections,** composed of forms requiring special rolls for producing the piling. If there are return bends, or flanges transverse to the plane of rolling, the piling must pass through a series of special rolls. (2) **Built-up sections.** Usually built up from standard structural steel shapes. These may consist of single webs with riveted interlocking members, or of double parallel webs held in relative position by bolts and pipe separators. The double-web sections are usually driven alternately with single web members. A number of forms of steel sheet piling are shown in Fig. 1. The following points need to be considered in selecting a design of piling for any work:

Water-Tightness.—In deep cofferdams a prime requisite is water-tightness. The clearance of interlock of adjoining piles must therefore be reduced as much as possible and still allow of driving. The clearances used on the built-up types are from $\frac{1}{4}$ -in. to $\frac{1}{2}$ -in. all around the interlock. In hard soils $\frac{1}{4}$ -in. is none too much. In many sections of piling over 15 ft. or 20 ft. long there will be found such kinks and crimps, partly the result of handling on and off cars, that driving with a tight interlock is a serious problem. With such a close interlock, piles not true or perfect in alignment often refuse to drive when there is encountered a stratum of hardpan or layer of small boulders. Under such conditions piling often

**Engineering-Contracting*, May 1, 1907.

refuses under the heaviest drop or steam hammer. If driving is persisted in it will result in the crippling of the pile either at the top or bottom. Crippling at the bottom means usually an escape from the interlock and a curving to one side exactly like a clinched nail except that the curve of the clinch may have several feet radius.

Fig. 3.—Representative Steel Sheet Pile Sections.

Stiffness.—In locations where there are encountered strata of hard material such as often occur in river valleys, where the drift has been eroded and redeposited, the steel piling to be a success must possess considerable stiffness laterally to prevent crippling. There-

fore examine the radius of gyration of the proposed section of piling. It is the writer's experience that for hard driving the free or unengaged edge (see X in No. 3, Fig. 3) of the pile being driven should be of a width (at right angles to the web) of one-third to one-half of the width of the engaged web (see Y in section No. 3, Fig. 3).

Methods of Driving.—The friction of long lengths of steel piling, with their inevitable crimps, will make necessary a heavy hammer, say a 4,500-lb. ram on a steam rig or a 3,000-lb. or heavier drop

Fig. 4.—Cast-Iron Follower for Driving Steel Sheet Piles.

hammer. Most of the writer's experience in driving steel sheeting has been with the heaviest No. 1 Vulcan steam hammer (4,500-lb. ram); total weight of hammer resting on the pile, 10,000 lbs. These hammers are adjusted to strike about 85 times per minute with 3 1/2-ft. stroke. These large (No. 1) Vulcan hammers are preferably fitted with a "McDermid base" consisting of a 1 1/2-in. circular steel plate about 13 ins. in diameter. These plates are slipped into

a slot in the base of the hammer housing and receive the blow of the ram. The wood striking block or cushion is set into the heavy cast-iron follower on the pile and projects up into the socket of the hammer housing so that the McDermid base plate rests directly on the wood block. These wood blocks are made about 26 ins. long, 15 ins. in diameter at the center, and are hewed to about 17 ins. at top and bottom to enter respectively the hammer housing and the follower.

In driving through hard clay layers, or when the piling is bored slightly by crimps in the interlock, the blows of such a hammer may run as many as 10 to 60 to the inch of penetration on such driving. In hard driving, one or two fresh blocks per 20-ft. pile are often required. The time consumed in stopping and changing blocks is from two to five minutes, provided the block is not badly split and wedged in. It is necessary to watch the failure of these blocks closely, as with a crushed or broomed block the efficiency of the hammer is very low. Therefore the blocks are removed as soon as they show signs of failure. The crushing usually takes place toward the middle of the length of the block, making a hot, steaming pulp of the tough oak or maple fiber for a length of 3 to 5 ins. Partially seasoned swamp oak, rock maple and blue gum have given the writer the best service.

The form of cast-iron follower used with steel piling, and shown in Fig. 4, was designed by the writer, and patterns are owned by the Vulcan Iron Works, Chicago, Ill., and the Jarvis Engine & Machine Works, Lansing, Mich. Fig. 5 shows a steel pile being driven, fitted with the cast-iron follower and the spindle-shaped follower block above described. Flat-base followers are sometimes used, but do not hold the steel pile in position.

Process of Driving.—In driving steel sheet piling, if the alternate sections are light and heavy (that is, the heavy piles having double webs or double "Z" bars), drive first a heavy section. Go slowly and take great care to have the initial pile plumb and exactly in position. Then interlock a light section with the first one driven. On account of time consumed in cutting off steel sheeting weighing 30 lbs. to 54 lbs. per sq. ft., it is always desirable to back the driver away from the work. In close quarters approaching a wall, or in the end of a deep cut for a cofferdam, for instance, this is not always practicable. In starting small cofferdams, as for piers or foundations on buildings where close adherence to the line is required, one of the manufacturers of piling recommends that temporary piles about 4 ft. long be driven and taken out one at a time, and the long pieces of piling substituted, thus insuring starting correctly with the long piling.

Borings in casings are made along the proposed line of steel sheeting at say 25-ft. intervals, and the steel ordered to length accordingly. Except when encountering rock, boulders or extremely tenacious hardpan, the piles can usually be driven to a fairly uniform top level. When the objective foundation soil or rock bottom is in an eroded river valley which has again been refilled with drift the hard bottom will frequently be covered with a generous number

of boulders which have dropped out of the eroded material because too heavy to be washed down stream. This boulder stratum is, of course, quite irregular and not so desirable a material in which to terminate sheet piling as a good clay or slightly disintegrated rock

Fig. 5.—View Showing Arrangement for Driving Steel Sheet Piles.
(A) Bottom of Steam Hammer; (B) Wooden Block; (C) Cast Iron Follower; (D) Steel Pile.

covering sound bedrock. Often too sound bedrock is deeply channeled and filled with pot holes, so that piling may need some cutting if it cannot be allowed to extend above grade, as into concrete

The process of cutting steel piling by means of the electric arc was employed on the construction of the foundations for the New Hoffman House, Broadway and 15th St., New York City. The cost of cutting steel piling with current at 10 cts. per kw. and the attendant at 50 cts. per hour, is stated to be as follows per foot of piling cut:

Cost of current.....	\$2.56
Labor	0.40
Total	\$2.96

This is rather high, and the hack-saw would probably be cheaper. However, with current at say 3 cts. per kw.-hour the cost per foot would be but \$1.17. Even at this rate, with labor competent to use a hack-saw at 25 cts. per hour, the saw would be the cheaper. The current used was at 50 volts, which was stated to be more satisfactory than either 25 or 105 volts. Tests showed 550 amperes consumed at the arc, which at 50 volts equals about 22 kw.

Boulders.—In passing a line of steel sheeting around a boulder of large size, special angle or bent piling sections are desirable to make the departure from and return to the line as planned. Some of the types of sheeting, like the Quimby or the United States, adapt themselves readily to such changes of alignment without using special pieces. Bending a $\frac{3}{8}$ -in. or $\frac{1}{2}$ -in. web longitudinally to short radius in the field is not an easy matter. When using rigid non-reversible interlocked piling in quicksand, and on work of such character that close water-tightness is required, special corner pieces should be kept on hand for emergencies. In some soils it may be permissible at times to turn corners by driving outside the interlock and tight against a projecting flange, placing the new piling at any angle required. Sometimes it may be feasible to fill gaps and make closures with specially prepared squared wood piles, with points beveled to make the wood piling hug the steel.

In hard driving among stones, only a type of piling of great stiffness laterally and with perfect interlocking features will insure success. On such work there must be no alternate unstiffened sections of piling. The interlock must be perfect and confining, difficult to open up and permit the escape of the inside member. Even with the heaviest and most confining type of interlocked piling now on the market in this country, this opening of interlock will sometimes occur when boulders are encountered. Small boulders in gravelly soils are usually displaced without trouble. Sometimes the aid of a water jet is a help. Usually steel piling will drive easily enough in ordinary soils without a jet. In hard clays a jet is not of much assistance and is very slow. Obviously it is not often required to drive steel sheeting far into hard clays.

In driving four lines of steel piling across the valley of the Muskegon River in Mecosta and Newaygo counties, Michigan, the borings showed "floating" masses of clay hardpan sometimes several hundred feet across, and from 1 ft. to 12 ft. thick. Below was quicksand before reaching a bed of hardpan continuous across the valley at a depth of about 30 ft. Hence the necessity for driving

through the floating hardpan. (See Fig. 6.) The hardpan in question consisted of about 70% of bluish clay and 30% of sharp sand, well mixed and compacted by water deposition and pressure, to the texture of frozen soil. In this hardpan were stones from gravel up to boulders of 5 tons weight. This material cost \$3 per cu. yd. to trench, and angular fragments would lie for months in water moving with a velocity of 5 ft. per second without material erosion or change in form. This was at the Big Rapids dam of the Grand Rapids & Muskegon Power Co., in 1905. Lubricating the piling with grease before driving, and with a stream of water under pressure when driving, seemed to be of no special aid in the hardpan mentioned.

On the work at the Big Rapids Dam, above mentioned, the single-channel Friestedt piling frequently buckled and recourse was then had to double Z-bar Friestedt sections entirely. This piling with two Z-bars on all pieces weighs about 54 lbs. per sq. ft., and to reduce the weight the writer has had a single Z-bar riveted to every channel instead of using double Z-bar channels exclusively or

Fig. 6.—Cross Section of Muskegon River at Big Rapids Dam.

alternating with plain channels. The single Z-bar to every channel permits always having the free or uninterlocked edge of the pile being driven stiffened by a Z-bar. On this type, shown at No. 3 in Fig. 3, the writer has obtained a patent and has used over 1,000 tons with satisfactory results. Nearly all of this was driven into hard soils. On the Muskegon River work one carload was used of a special rolled type of piling having less radius of gyration than the built-up types above mentioned. Of this piling fully one-half buckled; it was thrown away and replaced with the other type.

Pulling Piling.—The manufacturers of steel piling place much stress on the ability to pull up the piles, but in his experience in hard soils the writer has never been able to get jacks enough on a piece of steel piling driven 12 ft. in the ground to pull it out. In soft river mud and silt, pulling with heavy tackle can be done. Probably a hammer striking upward blows in the manner similar to that used in pulling pipe casings from test bore holes would be operative except in cases of badly crimped and bent piles. [Note.—Steel piles can be pulled with stump pullers, as described in the section on Timberwork.]

Cost of Piling.—In lots of 500 tons, Friestedt steel piling sold in 1904 and 1905 at \$1.93 per 100 lbs. on cars at the mill; this on alternate double Z-bar and channel and plain channel type. In

May, 1906, this type sold at \$2.03, and \$2.23 with a Z-bar on every channel, the additional price being on account of extra handling when every piece has to be riveted. The plain channels require only a 1-in. hole punched in the end for lifting.

The cost of driving per lin. ft. of piling 13½ in. net width, with a steam hammer, on the Muskegon River work above mentioned ran from 7¼ cts. to 20 cts. per sq. ft. in place; labor at 20 cts. per hour, foreman, 25 cts. The 7¼ cts. cost was on land in sand and gravel with some clay strata; piling 20 to 40 ft. long. The average amount of piling driven per hour in fairly good ground is 40 to 50 lin. ft., or 400 to 500 lin. ft. per day of 10 hours, including the time of moving the pile driver. In general the cost per sq. ft. for driving steel sheeting is 25% less than for driving wood.

Splicing Piling.—The longest single lengths driven on the writer's work was 44 ft., but spliced lengths up to 58 ft. have been successfully used. In doing spliced work it is not necessary actually to bolt or rivet the splices, the procedure being to use two lengths so as to break joints in the interlock. For 58-ft. piling, suppose we use 36-ft. and 22-ft. lengths: First drive the 36-ft. piece down, then move back and drive a 24-ft. pile down within a foot of the top of the 36-ft. piece; now move forward and set a second 22-ft. piece on top of the first 36-ft. piece and drive both down to full depth. Now move back past the 24-ft. pile and drive a 36-ft. piece in No. 3 position; then a 32-ft. piece on top of the 24-ft. piece. By moving back and forth so as not to lose the interlock below ground only two different lengths are required.

SUPPLEMENTARY DATA.

In addition to the cost given above in the original paper the author furnishes us some figures of the comparative cost of operating pile drivers by electric hoist and by steam hoist, and also further figures of the cost of sheet pile driving. These figures we give below.

Cost of Operating Pile-Drivers.—The following figures show the relative cost of operating two 2,000-lb. drop-hammer pile-drivers, one equipped with electric hoist and the other with steam hoist. These drivers had 38-ft. leads and worked side by side under the same conditions on round piling in sand and clay:

DRIVER WITH ELECTRIC HOIST.

One foreman, at \$3.....	\$ 3.00
Six helpers, at \$2.....	12.00
One team delivering at ½ day at \$4.....	2.00
Interest on investment at 5% (100 days' service)	1.00
Depreciation	1.00
Superintendence and engineering.....	2.00
Power	2.00
Total	\$23.00

In this driver the hammer was returned in the leads at a speed of 250 ft. per minute.

DRIVER WITH STEAM HOIST.

One foreman, at \$3.....	\$ 3.00
Five helpers, at \$2.....	10.00
One engineer, at \$2.25.....	2.25
One fireman, at \$1.75.....	1.75
One team delivering at $\frac{1}{2}$ day at \$4.....	2.00
Interest on investment at 5% (100 days' service).....	1.00
Depreciation.....	1.00
Superintendence and engineering.....	2.00
Fuel, $\frac{1}{2}$ ton coal, at \$4.....	2.00

Total\$25.00

In this driver the hammer was returned in the leads at a speed of 360 ft. per minute.

It will be noted that the electric hoist used was of considerably slower rope speed than was the steam hoist. Mr. Fargo notes that had the speed of the electric hoist been as great as that of the steam hoist it would have shown a lower cost record per lineal foot of piling driven on account of one less man at lower pay operating it. He states that any ordinarily bright man can be taught to operate an electric hoist in a day's time, but that a steam rig takes two men of more experience.

Cost of Driving Steel Sheet Piling with Steam Hammer.—The following figures show the cost per lineal foot of driving steel sheet piling in clay and sand, using a Vulcan steam hammer, with a 4,500-lb. ram and a total weight on the pile of 10,000 lbs. The driver had 55-ft. leads. The figures are for a 10-hour working day.

COST OF OPERATING DRIVER.

One foreman, at \$3.....	\$ 3.00
Four helpers, at \$2.....	8.00
One engineer, at \$2.50.....	2.50
One fireman, at \$1.75.....	1.75
One team delivering at $\frac{1}{2}$ day at \$4.....	2.00
Interest on investment at 5% (100 days' service).....	2.50
Depreciation.....	2.00
Superintendence and engineering.....	2.00
Fuel, 1 ton coal, at \$4.....	4.00

Total\$27.25

The steel piling, consisting of one 15-in. channel and one special Z-bar as shown in sketch 3, Fig. 1, weighed 38 lbs. per lin. ft. and cost delivered 2.385 cts. per lb. The record for 16 days' driving, 8 days of fairly difficult work in strong soil and 8 days of fairly easy driving in sandy soil, was 6,400 lin. ft., or 400 lin. ft., or 15,200 lbs. per day. We can now summarize as follows:

Item.	Per day.	Per lin. ft.
15,200 lbs., at 2.385c.....	\$362.52	\$0.9063
Unloading from cars, at $\frac{1}{2}$ c per lb....	76.00	0.1900
Operating steam hammer.....	27.25	0.0682
Total	\$465.77	\$1.1645

Cost of Cleaning Steel by Sand Blast and Painting by Compressed Air.—Dr. De Witt C. Webb gives the following:

At the U. S. Naval Station, Key West, Fla., are two large steel coal sheds whose vertical side walls are composed of $\frac{1}{4}$ -in. steel plates, and are from 18 to 20 ft. high. The action of heat and impurities in the coal, combined with that of the large quantities of salt water used for extinguishing spontaneous combustion fires rapidly corrodes the interior steel work and necessitates its thorough cleaning and painting every time the sheds are emptied.

Shortly after the writer was detailed to this station his attention was attracted to this subject, and he concluded that the use of a portable sand blast cleaning and spray painting outfit would be very advantageous in point of efficiency and time as well as cost. This idea meeting with the approval of the Bureau of Yards and Docks, the following outfit was purchased, at a cost of \$2,090, delivered at the naval station:

- 1 horizontal gasoline engine, about 20 hp.
- 1 air compressor, capacity about 90 ft. of free air per minute compressed to a pressure of 30 lbs. per sq. in. in one stage belt connected to engine.
- 1 rotary circulating pump, belt connected to engine.
- 1 galvanized steel water tank.
- 1 air receiver, 18 x 54 ins.

(The above apparatus was all mounted on a steel framed wagon with wooden housing.)

- 2 sand blast machines, capacity 2 cu. ft. of sand each.
- 2 paint spraying machines, one a hand machine of $\frac{1}{2}$ gal. capacity for one operator, the other of 10 gals. capacity for two operators.
- 100 lin. ft. of sand blast hose.
- 200 lin. ft. of pneumatic hose for sand blast machines.
- 400 lin. ft. of pneumatic hose for painting machines.
- 100 lin. ft. of air and paint hose for painting machines.
- 4 khaki helmets, with mica-covered openings for the eyes.
- 200 lin. ft. of 2-in. galvanized iron pipe.

Previously to the delivery of this material shed "A" had been emptied of coal and the work of cleaning the inside surface of the wall plates was begun by hand in the usual manner. About 7,000 sq. ft. out of a total of 9,000 were thus cleaned at a cost of slightly over 4 cts. per sq. ft. On the arrival of the sand blast outfit the hand work was stopped and after a short preliminary trial the machine cleaning was started. The work proceeded rather slowly until the men became accustomed to it, yet the 2,000 sq. ft. of previously untouched surface was thoroughly cleaned and the 7,000 sq. ft. of hand cleaning was all gone over and much improved at a

total cost for labor of \$97.68 and for gasoline of \$16.15. The force consisted of the following:

	Per day.
1 engine tender	\$ 3.04
1 helper (in charge of the work and tending machines)	2.24
2 laborers on machines, at \$1.76 each.....	3.52
1 laborer drying sand, filling machines, etc.....	1.76
Total	\$10.56

From 10 to 15 gal. of gasoline were required per day of 8 hours (costing 19 cts. per gal. here).

For the painting the coal tar paint originated by Civil Engineer A. C. Cunningham, U. S. N., was used. This paint was prepared with the following proportions (by volume): Coal tar, 4 parts; kerosene oil, 1; Portland cement, 1.

The Portland cement was first well stirred into the kerosene oil, forming a creamy mixture; this mixture was then carefully stirred into the coal tar. It was freshly mixed as needed and kept well stirred. The cost of this paint at Key West is about 15 cts. per gal. It was found not to be so well suited to the pneumatic spraying machine as oil paint, but worked very well; though, of course, the machine used considerably more than hand work. In all, on this shed, 64½ gal. of paint were required for 9,000 sq. ft., or about 1 gal. to 140 sq. ft. The force used in painting was the same as in cleaning, with the addition of a laborer, who followed up the painters with a long handled brush and spread the paint uniformly. The cost of painting this shed was: For labor, \$32.16; for gasoline, \$3.80.

On shed "B" a total area of 12,500 sq. ft. was cleaned and painted. This steel work was covered with a scale nearly ½ in. thick and was deeply pitted. The scale and rust were very tough and extremely hard to remove. On this work it was found economical to keep men ahead of the sand blast with sledges, loosening and shaking off as much of the scale as possible. The labor cost of the whole work on this shed (cleaning and painting) was \$460, including the cost of moving, setting up and removing. Gasoline cost \$81. A total of 85 gallons of coal tar paint was used, covering about 145 sq. ft. per gal. Total cost of labor, fuel and paint, \$553.90, or 4.4 cts. per sq. ft. It is impossible to separate the cost of cleaning and painting on this work, as only small areas are painted at one time, the painting being done by one operator, the other working the sand blast. This was done in order to expose the cleaned steel to the atmosphere for as short a time as possible.

A fine silica sand was used, that being the only kind available except coral sand, which was tried, but found to be too soft. A coarse sand would probably have been more effective. The sand was all saved, dried and re-used several times. About ½ cu. yd. of fresh sand was required daily. The sand must be kept perfectly dry for this purpose, and there are patent sand driers manufactured. Very good results were obtained on this work, however, by the use

of a sheet of boiler plate set up on bricks with a wood fire underneath.

No claims are made of extreme economy in the above work. The extremely thick and tough scale to be removed, the high fuel and labor cost of compressing air simply for this work, and (probably) the lack of the best kind of sand for the purpose, combined to make the work expensive. With these drawbacks it was, however, considerably cheaper than hand work and, what is more important, the cleaning was much more effective and thorough than could possibly have been done by hand.

SECTION XIV.

ENGINEERING AND SURVEYS.

Cost of Engineering.—When work is done by contract, engineering costs from 2 to 10% of the total cost of construction. This includes surveys, plans, estimates and inspection during construction. The major part of this cost is usually the supervision and inspection of the contractor's work. Hence, if the job is small, and if the work drags, the cost of engineering will approach, or even exceed, 10%.

Throughout this book are given actual records of the cost of engineering, for which consult the index under "Engineering."

Engineering Charges For Services.*—The following information as to the minimum charges for engineers' services in Iowa, was collected by the Secretary of the Iowa Engineering Society and printed in the Proceedings of the 21st annual meeting of the society:

Expert Services:

One day	\$50.00
Each additional day	25.00
Expert testimony, per day	50.00
Services of hydraulic or sanitary engineer in examinations, reports, estimates, per day	25.00
Construction engineer's and detail work, per day	10.00
Special rates for corps of engineers and inspectors to take charge of work according to importance and degree of skill required.	

City Surveys and General City Work:

Field and office work, per day of 8 hours	8.00
First assistant, per day of 8 hours	4.00
Second assistant, per day of 8 hours	2.40
Time taken going to and returning from survey to be included in above 8 hours. Not less than half a day to be charged.	
Surveys of single city lots, not less than	6.00
Unless previous surveys have been made of adjoining lots in same plan, then	
No description to be drawn for less than	5.00
No charge to be less than	1.00
Laying out of additions of not less than 20 acres, \$1.00 per lot, to include working plats and plat for record; but owner must furnish the design of plat or else pay engineer for time consumed in determining method of division.	
All expenses, such as railway fare, hotel expenses, conveyances of any kind, posts, monuments, are to be charged for as extra.	

County Land Surveys by County Surveyor:

Fees prescribed by law. Surveyor, 50 cts. per hour; assistants, 20 cts. per hour. All expenses are allowed and charged for as extra.

**Engineering-Contracting*, Oct. 20, 1909.

There seems to be doubt as to what constitutes a day for a County Surveyor, but, as the law prescribes 8 hours in county road work and various other service, it is safe to say that 8 hours is a legal day, and it has been held so in the courts.

Cost of Engineering on City Work.—During the years 1901 to 1906, some \$2,133,000 were spent for sewers, waterworks and pavements in Salt Lake City, Utah, and the engineering cost 4.8% of this amount.

Cost of Engineering in Reservoir Construction.*—On the East Branch, the Carmel, the Titicus and the Jerome Park reservoirs for New York City, the cost of engineering averaged 10% of the construction cost of \$9,532,000. This engineering includes all surveys, test borings, designs and inspection. However, 10% is a very high percentage of cost for work of such magnitude.

Rations for Men Camping.—In the rules for a railway location prepared by McHenry for surveying parties on the Northern Pacific Ry., the following list of rations and supplies is given: The food is sufficient to support 14 men at least 30 days.

400 lbs. flour.	2 lb. ground pepper.
50 lbs. buckwheat.	1/4 lb. ginger.
40 lbs. oatmeal.	1/4 lb. cinnamon.
30 lbs. cornmeal.	1/4 lb. allspice.
25 lbs. rice.	1/4 lb. nutmegs.
10 lbs. tapioca.	1 bottle lemon extract.
10 lbs. sago.	1 bottle vanilla extract.
10 lbs. barley.	6 bottles pickles.
10 lbs. cornstarch.	6 bottles catsup.
10 lbs. baking powder.	8 bottles Worcester sauce.
3 lbs. soda.	100 lbs. ham.
12 packages yeast cakes.	100 lbs. bacon.
150 lbs. sugar.	25 lbs. dried beef.
20 lbs. salt.	25 lbs. codfish.
50 lbs. coffee.	40 lbs. lard.
10 lbs. tea.	25 lbs. cheese.
5 gals. syrup.	50 lbs. butter.
1 gal. vinegar.	1 case cornbeef.
400 lbs. potatoes.	50 lbs. dried apples.
50 lbs. beans.	50 lbs. dried peaches.
20 lbs. onions.	50 lbs. dried prunes.
2 cases (24 qts.) tomato.	10 lbs. dried currants.
2 cases corn.	1 box raisins.
1 case peas.	1 box crackers.
1 case pears.	1 box macaroni.
1 case cherries.	1 box soap.
2 cases peaches.	12 boxes matches.
1 case milk.	1 box candles.
1 case coal oil.	2 lbs. lye.
2 lbs. mustard.	10 lbs. sal-soda.

The total net weight of food in this list is about 2,100 lbs., or about 5 lbs. of food per man per day, on the basis of 420 man-days. This is certainly ample. In fact men can live on much less if concentrated food that swells on cooking is used. The following is a

*Engineering-Contracting, July 8, 1905

List used by the author on a 30-day camping expedition where every superfluous pound of weight was cut out:

	One man. 30 days.	One man. 1 day.
Flour	25 lbs.	0.83 lb.
Oatmeal	8 lbs.	0.27 lb.
Rice	4 lbs.	0.14 lb.
Beans (dried)	8 lbs.	0.27 lb.
Sugar	12 lbs.	0.40 lb.
Salt	1 lb.	0.03 lb.
Butter	2 lbs.	0.07 lb.
Bacon	10 lbs.	0.33 lb.
Baking powder	1 lb.	0.03 lb.
Coffee	2 lbs.	0.07 lb.
Tea	$\frac{1}{2}$ lb.	0.01 lb.
Dried prunes	2 lbs.	0.07 lb.
Pepper	$\frac{1}{2}$ lb.	0.01 lb.
Condensed milk	3 cans	0.10 lb.
Total	79 lbs.	2.63 lbs.

This list furnishes 0.23 lb. nitrogenous food, 0.30 lb. fat, and 1.30 lbs. starch and sugar per man per day. Dr. Pavy (*Encyclopedia Britannica*) states that a laborer requires daily 0.25 lb. nitrogenous food, 0.10 lb. fat, and 1.18 lbs. starch and sugar (carbohydrates). If the trip is to be a long one, $1\frac{1}{2}$ oza. of juice of lime per man per day should be taken to prevent scurvy, unless potatoes can be carried along.

F. W. D. Holbrook, in *Jour. Assoc. Eng. Soc.*, 1883, p. 180, gives the following rations for 20 men for 12 days, where all food has to be packed on the backs of men (1,400 lbs. of food for 240 man-days):

12 bottles prepared mustard.	100 lbs. granulated sugar.
25 lbs. butter.	50 lbs. brown sugar for syrup.
170 lbs. ham.	10 lbs. tea.
75 lbs. canned cornbeef.	15 lbs. coffee.
50 lbs. mess pork.	70 lbs. beans.
300 lbs. flour.	25 lbs. rice.
25 lbs. dried apples.	$\frac{1}{2}$ lb. ground pepper.
25 lbs. dried peaches.	$\frac{1}{2}$ lb. ground ginger.
50 lbs. prunes.	1 lb. ground cinnamon.
25 lbs. raisins.	12 lbs. soap.
10 lbs. currants.	15 lbs. candles.
12 lbs. baking powder.	6 boxes matches (300 in box).
10 lbs. salt.	

The U. S. Geological Survey ration list is as follows for 1 man for 100 days:

- 100 lbs. fresh meat, including fish and poultry.
- 50 lbs. cured meat, canned meat, or cheese.
- 15 lbs. lard.
- 80 lbs. flour, bread or crackers.
- 15 lbs. cornmeal, cereals, macaroni, sago or cornstarch.
- 5 lbs. baking powder or yeast cakes.
- 40 lbs. sugar.
- 1 gal. molasses.
- 12 lbs. coffee.
- 2 lbs. tea or cocoa.
- 10 cans condensed milk, or 50 qts. fresh milk.
- 10 lbs. butter.
- 20 lbs. dried fruit, or 100 lbs. fresh fruit.
- 20 lbs. rice or beans.
- 100 lbs. potatoes or other fresh vegetables.
- 30 cans of vegetables or fruit.
- 4 ozs. spices.
- 4 ozs. flavoring extracts.
- 8 ozs. pepper or mustard.
- 3 qts. pickles.
- 1 qt. vinegar.
- 4 lbs. salt.

Eggs may be substituted for fresh meat in the ratio of 3 eggs for 1 lb. of meat. Fresh meat and cured meat may be interchanged on the basis of 5 lbs. of fresh for 2 lbs. of cured. Dried vegetables may be substituted for fresh vegetables in the ratio of 2 lbs. of fresh for 1 lb. of dried.

This ration weighs 5.3 lbs. per day per man, and it costs about 50 cts. per day per man. The list was based originally on the U. S. army ration, but has received some modifications dictated by experience.

Cost of Rations, U. S. Reclamation Service.*—From the annual report of the U. S. Reclamation Service for 1904-5, the cost of rations for the employees of that body, engaged on several of the reclamation projects, were from 40 to 80 cts. per man per day, averaging about 55 cts.

Equipment For and Cost of Railroad Surveys.—Mr. F. Lavis in his admirable book on "Railroad Location, Surveys and Estimates," has given valuable information on railway surveying and estimating, from which the following data have been abstracted:

The following is a list of the camp outfit:

- 1 office tent with fly, 14 x 16 ft.
- 3 drafting and office tables.
- 3 tents, 14 x 16 ft.
- 4 camp chairs.
- 1 cook tent, 16 x 20 ft.
- Map chest with necessary stationery, paper, etc.

**Engineering-Contracting*, Oct. 24, 1906.

DINING TABLE.

- 3 dozen agate ware dinner plates.
- 3 dozen agate ware cups.
- 2 dozen agate ware saucers.
- 2½ dozen steel knives.
- 2½ dozen steel forks.
- 2½ dozen German silver teaspoons.
- 1½ dozen German silver dessert spoons.
- 1 dozen German silver tablespoons.
- ½ dozen tin salt boxes.
- ½ dozen tin pepper boxes.
- ½ dozen round agate ware pans, 3 qt.
- ½ dozen round agate ware pans, 1 qt.
- 1 dozen round agate ware pans, 1 pt.
- 1 carving knife and fork.
- 7 yds. oilcloth, 48 ins. wide.
- 3 standard trestles.
- 6 boards, 12 by 1½ ins. by 18 ft. (dressed).

COOKING UTENSILS.

- | | |
|--------------------------------------|---|
| 1 No. 8, 6-hole, wrought-iron range. | 1 small frying pan. |
| 1 tea-kettle. | 2 griddles. |
| 1 large cast-iron pot. | 4 tin pans with covers, 1 gal. each. |
| 1 small cast-iron pot. | 2 stewpans. |
| 2 large frying pans. | 1 3-gal. coffee-pot. |
| 1 gal. teapot. | 1 chopping bowl. |
| 4 dripping pans. | 1 bread board. |
| 6 baking tins for bread. | 1 rolling-pin. |
| 12 tin pie plates. | 1 biscuit cutter. |
| 2 butcher knives. | 1 nutmeg grater. |
| 1 steel. | 1 coffee mill. |
| 2 large meat forks. | 1 spring balance. |
| 1 chopping knife. | 6 galvanized iron buckets. |
| 1 meat saw. | 6 tin dippers (one for each tent and two in cook tent). |
| 2 large iron spoons. | 2 can openers. |
| 1 soup ladle. | 1 corkscrew. |
| 1 cake turner. | 1 broom. |
| 1 flour sieve. | 1 scrubbing brush. |
| 1 colander. | 1 alarm clock. |
| 1 5-gal. tin dishpan. | 1 table (same as drafting tables). |
| 1 5-gal. tin bread pan with cover. | |

MISCELLANEOUS.

- ¼ dozen Dietz lanterns.
- 3 large tin lamps (central-draft, round wicks).
- 2 large galvanized-iron washtubs.
- 1 washboard.
- 4 Sibley stoves (4 lengths of pipe with dampers, 12 lengths of plain pipe).
- 2 water kegs, 2 gals. each.
- 6 washbasins.

TOOLS.

- | | |
|----------------------------|-------------------------------|
| 1 grindstone and fittings. | 4 chopping-axes. |
| 1 monkey wrench. | ¼ dozen axe handles. |
| 1 pick. | 1 bundle sail twine. |
| 2 shovels. | ¼ dozen sail needles. |
| 1 short crowbar. | 1 sail palm. |
| 1 hand-saw. | 10 assorted sizes wire nails. |
| 1 cross-cut saw. | 100 ft. manilla rope, ¾-in. |
| 2 hand-axes. | |

LUNCH BOX.

- 2 dozen agate ware dinner plates.
- 2 dozen agate ware saucers.
- 1½ dozen steel knives.
- 1½ dozen steel forks.
- 1½ dozen German silver teaspoons.
- 1½ dozen German silver dessert spoons.
- 1 2-gal. coffeepot.

Each locating party was organized as follows:

Locating engineer	\$150 to \$175
Assistant locating engineer.....	115 to 125
Transitman	90 to 100
Leveler	80 to 90
Draftsman	80 to 90
Topographers, two*	80 to 90
Rodman	50
Head chainman	50
Rear chainman.....	40
Tapeman, two*	30
Back flagman	30
Stake marker	30
Axemen (three to five as necessary).....	25 to 30
Cook	50
Cook's helper	20
Double teams and driver, furnish their own feed, driver board in camp	65 to 90

*One of the topographers assisted by two tapemen, with a transit determined land lines and drainage areas.

Each man was supplied by the company with subsistence when in camp, but was required to provide himself with an army cot and sufficient bedding, and advised to provide a substantial canvas covering for the latter, an ordinary wagon cover, costing from \$3 to \$5, being the most easily obtainable and most satisfactory.

Most of the lines ran through a rather badly broken up, rolling country (Indian Territory, Oklahoma and Texas), with short cross-drainage, about 75% being wooded. Topography was taken 300 ft. on each side of the line, a hand level and rod being used, distances out were placed, and 5-ft. contours located and sketched. The average amount of grading was 100,000 cu. yds. per mile;; maximum grade, 0.5%; maximum curve, 2°. The cost of the surveys was as follows for 563 miles of preliminary and 183 miles of located lines:

PRELIMINARY LINES.

	Party No. 1. July 5th to October 1st.	Party No. 2. July 23d to October 20th.	Party No. 3. Aug. 1st to Nov. 19th.	Party No. 4. Sept. 21st to October 21st.
	87 days.	90 days.	111 days.	30 days.
Miles run and topography taken.	145.8	166.3	164.1	23.2
Miles run, no topography taken..	39.3	16.0	3.6
Total miles preliminary run.....	185.1	166.3	180.1	21.8
Total number payroll days.....	1280	1323	2023	635
Average daily number of men....	15.9	14.7	18.3	21.2
Average miles per day per party.	2.12	1.85	1.62	1.06
Average daily cost, subsistence per man	\$0.37	\$0.49	\$0.33	\$0.53
Average daily pay per man....	1.81	2.03	1.66	1.66
Daily cost for teams.....	6.00	6.22	6.92	12.87
Contingencies	33.48	112.95	91.84	125.73
Daily cost of party.....	41.72	44.48	45.57	64.81
Cost per mile.....	19.61	24.87	28.08	60.95

LOCATED LINES.

	Party No. 1.	Party No. 2.	Party No. 3.	Parties Nos. 2 and 3 Combined.	Party No. 4.
	65 days.	27 days.	8 days.	48 days.	66 days.
Miles located	56.0	37.8	7.6	42.6	39.3
Total number payroll days	1400	709	151	1498	1283
Average daily number of men	21.5	19.0	19.0	31.2	19.4
Average miles per day per party	0.86	1.02	0.95	0.89	0.59
Average daily cost sub- sistence	\$0.37	\$0.39	\$0.39	\$0.40	\$0.45
Average daily pay per man	1.72	1.61	1.61	1.71	1.60
Daily cost for teams...	6.69	6.75	6.23	10.83	6.76
Contingencies	143.36	46.76	15.70	196.00	123.84
Daily cost of party.....	53.90	45.22	45.13	80.29	48.54
Cost per mile.....	62.57	44.33	47.50	90.47	81.73

The preliminary lines run by Party No. 1 were over a severe country, involving the heaviest construction work on the whole line. Party No. 3 also had much difficulty in getting a grade between certain points. Party No. 2 had the lightest country. Party No. 4 worked only a short time and the cost of moving a long distance from other work is included. It is probable that the cost of work done by this party was really about 60% more than the others per mile, instead of 100% more.

On the locating work, Party No. 1 had an expensive sounding party consisting of a man in charge, 4 or 5 laborers and a team.

Parties Nos. 2 and 3 were combined, after each had run a short distance of located line separately, which increased the unit cost of the located line, as shown.

The total cost of 183 miles of located line was \$132 per mile of located line, and this includes the cost of running the preliminary lines.

Cost of 2,000 Miles of Railway Surveys.—In a paper by Mr. W. S. McFetridge, published in *Trans. Am. Soc. C. E.*, 1909, and reprinted in *Engineering-Contracting*, May 19, 1909, is given a very complete description of the methods of making 1,400 miles of preliminary and 600 miles of location surveys. The following is a very brief summary of the cost.

Field parties were made up as follows:

	Monthly Salary.
Assistant engineer in charge.....	\$125 to \$150
Transitman	85 to 100
Levelman	75
Rodman	65
Head chainman	50
Rear chainman	45
Rear flagman	40
Stakeman	35
Axeman (from two to five).....	20
Topographer	65
Tapemen (two)	45
Draftsman (part time).....	60

Camp outfits were not used. The parties boarded at houses along the line. This was often a disadvantage, on account of difficulty in getting quarters, especially for a full corps; but, on the other hand, the party could frequently make its headquarters at some town and drive to and from the work, so that probably this method served just as well as furnishing camp outfits.

It may appear to some that there was much unnecessary location and running of preliminary lines, but in rough country like this, and on work of this magnitude (in 220 miles of this line were 21 tunnels, the longest being 4,000 ft., 5 viaducts from 400 to 1,000 ft. long, and more than 100 ft. in height, besides numerous other bridges), it is time and money well spent. In no other way can the exact data be gotten, and it leaves no question as to the available routes and the grades obtainable. The topography was taken (on practically all lines) accurately by using a metallic cloth tape for distances and a hand-level for elevations. Only in this way can one get a projected location to correspond closely with the actual one. The topography was ordinarily taken for 300 ft. on each side of the center line; at particularly difficult summits or similar places a strip from 1,000 to 2,000 ft. wide was often shown. The lines were plotted to a scale of 200 ft. to 1 in. The topography was plotted in the field. A hollow drawing-board, 18 x 24 ins. was used. The sheet in use was tacked to the board, and the additional sheets were carried inside. A strap around the shoulders of the topographer served to carry the board, and formed a support while plotting (Wellington's method).

TABLE I.

Miles of Survey.						
Company (1)	Amount Spent. (2)	Prelimi- nary. (3)	Location. (4)	Total. (5)	Av. cost per mile. (6)	Av. cost per mile of location. (7)
L. M. R. R.....	\$25,076.83	428.19	193.35	822.04	\$40.31	\$129.36
Z. M. & P.....	19,812.77	509.03	105.23	614.26	32.25	198.28
B. & E. R. R.....	20,460.68	241.75	113.70	355.45	57.58	180.00
P. B. & T. R. R.....	6,661.93	34.56	33.17	123.73	54.20	174.28
B. & N. R. R.....	19,249.94	162.51	151.29	313.80	61.34	127.23
Totals	\$91,352.20	1,426.04	602.24	3,028.28	\$45.00	\$151.53

Cost.—The greatest number of miles of preliminary line run in one day by one party was 7, and of location, $4\frac{1}{2}$. The location averaged slightly more than 1 mile per day per party, except on two lines, where it averaged $\frac{1}{2}$ mile. Stakes were set every 100 ft. on tangents, and every 50 ft. on curves. Special pains were taken with the instrument work and measurements, in order to avoid the chance of serious errors in the center line after construction commenced. The speed of location parties was usually limited by the amount of clearing that could be done, but the number of curves and the rough character of the ground were also large factors in limiting the speed.

Each party cost from \$35 to \$40 per day, being allowed all expenses in addition to salaries.

Table I gives the cost per mile of the completed surveys. It is to be noted that this is the total cost, and includes office rent, purchase of instruments and supplies, general expenses, all salaries, field expenses, and the preparation of final maps, plans, profiles, and estimates, with everything in readiness to make contracts for the line.

Column 7 gives the cost per mile of actual location, including preliminary lines. Columns 3 and 4 show that there were from 2 to 5 miles of preliminary lines run for each mile of location, except on one line. Table I also includes 302 miles of check levels, the cost being distributed among the various accounts. The data for the Parkersburg Bridge and Terminal line include surveys and soundings for the Ohio River Bridge. The cost per mile includes the topography on practically all lines, except one where it was taken only on the located lines.

The cost shown in Table I being the total charge against engineering from the inception of the project to the beginning of construction, contains a few items which might well be charged to other accounts than location. Instruments purchased could be a credit; some elaborate property surveys and bridge surveys could be charged to construction, but they probably are not large enough to have much effect on the cost per mile. If taken into account, they would reduce the cost.

A line run in midwinter may easily cost one-quarter more than if run during more favorable weather.

TABLE II.

—Average Cost of One Mile.—

Company—	Of preliminary.	Of location.	Of location including preliminary.
L. K. R. R.....	\$25	\$ 74	\$ 99
Z. M. & P. R. R.....	23	79	102
B. & E. R. R.....	25	105	140
B. & N. R. R.....	31	94	125

The figures in Table II include all expenses, as in Table I.

Table I shows a large variation in the cost of surveys on different divisions, the cost varying from \$128 to \$188 per mile, with an average of \$151. On the assumption that lines located for comparison or similar purposes should be included in the average, one-third

should be added to these amounts, as previously noted; the cost would then be as follows:

Low	\$171 per mile
High	251 per mile
Average	202 per mile

Throwing out of the account the mileage of abandoned lines, branch lines, etc., and charging the entire cost to the main line,

\$91,258.20

terminus to terminus, would give $\frac{\text{---}}{328} = \278.23 per mile,

328

which would be rather expensive. This, however, is not a fair assumption, and should not be considered, because many miles of lines not needed to determine the main line were located for other reasons and purposes. Therefore, the plan of throwing out only duplications, for comparisons, as shown in the preceding paragraph, gives the correct average cost per mile for the development of the country, including actual comparative locations where needed. It should also be borne in mind that a large proportion of this duplication was necessary, owing to the laws of West Virginia, which require an actual line, located on the ground, and a complete map and profile of that line to be filed with the Secretary of State, and at the county seat, before a railroad company has any rights, of priority or otherwise, to that route or line. This required complete locations for all proposed branch lines, a large number of which were located, and also a complete location over any route for which it was desired to obtain rights. For these reasons, the lines located account for the excess of the mileage over the actual length of the main line.

On the basis of Table II, it may be assumed that, where the route has been previously determined within such narrow limits that the preliminary and location lines are of equal length, the surveys will cost from \$100 to \$140 per mile. This is borne out by the results on the Buckhannon and Northern line, where the location and preliminary lines were practically equal and the cost was \$127 per mile.

These two statements may be combined and put in the following form:

To locate one mile, including an equal length of preliminary lines, cost from \$100 to \$140; average.....	\$115
To locate one mile, final location, including from two to five times as great a length of preliminary lines, cost from \$128 to \$188; average.....	151
To locate one mile, final location, including from two to five times as great a length of preliminary lines, and one-third of a mile of location for comparison, cost from \$171 to \$251; average	202

A tabulation of the mileage of the Buckhannon and Northern line, with reference to the actual length of line to be built, and showing how the results agree with the averages deduced from Table I, is as follows, the Buckhannon and Northern line being used because the conditions there make it the best average of "all conditions" encountered on the various lines.

Total miles located.....		151.23
Miles of main line contracted for.....	80	
Miles of main line not contracted for.....	4	
Miles of connecting line located, but which may or may not be built, about.....	26	110.00
Making actual miles.....	110	
Leaving duplications, comparisons, etc.....		41.23
110 miles cost \$19,249.94 = \$175 per mile.		

Cost of a Railway Survey, Canada.*—The following data relate to a survey made in Canada in 1906 for the Grand Trunk Pacific Ry. The lines were run through gently rolling prairie country, with three rather difficult river crossings. The topography was taken 800 ft. on each side of the line, locating 5 ft. contours. The maximum grade was 0.4%, and the maximum curve was 4°. Some rather fast work was done in the survey, for on Oct. 10 12.46 miles of line was located in 8 hours and 20 minutes. An average of 3.4 miles per day was also made in 22 days worked. The organization of the party and wages paid were as follows:

	Per month.
Locating engineer	\$ 175.00
Transitman	100.00
Levelman	75.00
Topographer	75.00
Draughtsman	75.00
Head flag	45.00
Level rodman	45.00
Head chainman	45.00
Rear chainman	30.00
Topog. chainman	30.00
Topog. rodman	30.00
Rear flagman	30.00
Stakeman	30.00
Axeman	30.00
Cook	60.00
Cooker	20.00
One saddle horse	20.00
Three teams at \$100.....	300.00
Total	\$1,235.00

The following is a record of the cost of the survey and the work accomplished:

	Preliminary.	Location
	24	60
	Days	Days
Miles run and topography taken.....	175.3	208.0
Total miles location and alternative location..	208.0
Total miles preliminary run.....	175.3
Total number payroll days.....	384.0	960.0
Average daily number men.....	16.0	16.0
Average miles per day.....	7.3	5.13
Daily cost of subsistence per man.....	\$ 0.41	\$ 0.41
Average daily pay per man.....	1.85	1.85
Daily cost for teams.....	10.67	10.67
Contingencies	18.00	77.00
Daily cost of party.....	47.83	47.83
Cost per mile.....	6.65	9.33

* *Engineering-Contracting*, Feb. 19, 1908.

The survey was made under the direction of Mr. C. J. Seymour, Kansas City, Mo., to whom we are indebted for the above information.

Cost of Reconnaissance Survey for Railway in Alaska.*—Mr. Fred Lavis is author of the following:

The following costs of a reconnaissance survey for railroad location in Alaska in the winter of 1906-7 were furnished the writer by Mr. H. R. Gabriel, Locating Engineer, Katalla, Alaska. The payroll was as follows:

	Per month.
Chief of party.....	\$ 350
Transitman	125
Topographer	100
Draftsman	100
4 dog mushers	400
2 axemen	200
1 rodman	100
Cook	100
Total	\$1,376

The total cost of the survey was \$13,500, distributed as follows:

Salaries	\$ 8,050
Subsistence	2,810
Cost of 22 dogs at \$60 each.....	1,320
Feed for dogs.....	1,320
Total	\$13,500
Average cost \$50 per mile.	

The survey covered a route 270 miles long between Fairbanks and Seward, Alaska, and was made between Jan. 1 and May 25, 1907. For a period of three weeks no work was done, the temperature ranging from 60° to 70° below zero, but work was carried on when the temperature was 36° below. The dogs were worked in four teams and on newly broken trails hauled 500 lbs. per team; they were fed on bacon, rice and fish which cost 40 cts. per day per dog.

The camping equipment was very light, consisting of one 10 x 12 ft. and two 14 x 16 ft. tents, two Yukon stoves and but very few ~~blanks~~.

The average distance between camps was 10 miles, and but 4 or 6 days were spent in each camp.

The following is the list of rations allowed:

*Engineering-Contracting, Dec. 9, 1908.

	Lbs.
Flour per man per day.....	1 to 1.25
Beans per man per day.....	0.25 to 0.50
Rice per man per day.....	0.12
Bacon per man per day.....	0.12 to 0.25
Ham per man per day.....	1.00
Dried fruit per man per day.....	0.20 to 0.25
Dried corn per man per day.....	0.10
Sugar per man per day.....	0.20
Butter per man per day.....	0.16
Salt per man per month.....	0.75
Pepper per man per month.....	0.05
Other spices in proportion to pepper.	
Tea per man per month.....	0.50
Coffee per man per month.....	0.57
Cocoa per man per month.....	0.33
Dried potatoes per man per day.....	0.08
Rollod oats per man per day.....	0.08
Corn meal per man per day.....	0.08
Canned milk (can) per man per day.....	0.16
Macaroni per man per day.....	0.14
Cheese per man per day.....	0.08
Lard per man per day.....	0.05
Crystal eggs per man per month.....	0.33
Baking powder 1.5 lbs. per 50 lbs. flour.	
Yeast cakes, 12 men per month, 10 pkgs.	
Soda, 12 men per month, 1 pkg. Sour dough bread was used.	
Concentrated vinegar, 12 men 6 months, one 4-oz. bottle.	
Mustard, 12 men 6 months, 4.5 lbs.	
Olive oil, 12 men 1 month, 0.1 gal.	
Beef tea, 12 men 1 month, 20 jars.	

This reconnaissance was a stadia survey, all distances both vertical and horizontal being measured with the transit, no level was used; topography sufficient to make a rough projected location and fairly accurate profile where it varied from the main line run, was taken with a clinometer.

It will be noted that all the information necessary to make a fairly accurate projected location was obtained on this survey at a comparatively small cost. Its value lies somewhere between the ordinary reconnaissance and the so-called preliminary location which should properly be a preliminary survey.

A preliminary survey of this line if properly made would have given more accurate detailed information, but its cost would have been between \$250 and \$350 per mile according to statements of actual costs of preliminary surveys in Alaska, made by Messrs. Cryderman and Kyle in a paper read before the Pacific Northwest Society of Engineers early this year.

The stadia furnishes accurate (within the really necessary practical limits) information as to distance, direction and elevation, which can be obtained in no other way as cheaply, and without any one of which it is impossible to form any reliable estimate of the practicability of any line or its cost, the addition of a very limited amount of topography taken by an experienced topographer enables a projected location to be made which should be well within a close approximation of the final line,

In regard to the salaries given they seem too low. The transitman, topographer and draftsman were not paid any more than good men get in the older parts of the United States where conditions of existence are not so rigorous; without intending any reflection on the men composing the party, the writer believes that in these positions competent men would be worth at least 50% more than was paid on this survey.

Cost of Locating Two Railroad Lines in Michigan and Wisconsin.* One line was located from Traverse City to Elk Rapids and from Williamsburg to Petosky. The survey was begun Sept. 1, 1889, and finished May 1, 1890. The country was covered with heavy hardwood and hemlock timber and dense cedar swamps. The ground was alternately flat and very rough, in sections of 6 to 10 miles in length. About 25 miles of the 91 were located on the shores of small lakes bounded by steep bluffs which came down close to the shore, the latter being very irregular. The winter was a light one, except in February, when the snow was 3 ft. deep, which considerably reduced progress.

The following was the organization of the party, and the monthly cost of making the survey:

	Per month.
Chief of party.....	\$ 100.00
Transitman	75.00
Leveler	100.00
Rodman	40.00
Chainman, head	40.00
Chainman, rear	30.00
Back flagman	30.00
4 axemen at \$30.....	120.00
Cook	40.00
Cooker	15.00
Team and driver.....	90.00
1/2 time of Division Eng., at \$125.....	62.50
Expense of camp.....	270.00
Total	\$1,012.50

The survey occupied 8 months, making the total cost \$8,100, which is equivalent to \$89 per mile of located line, there being 91 miles located. The total number of miles of line run, including preliminary lines, was 250 miles. Stated otherwise, there were nearly 3 miles of preliminary line run to each mile of located line.

In all there were 208 working days, but, in moving and on account of bad weather, 20% of this time was lost, thus reducing the actual number of days worked to 188. The following was the amount of line run per day:

	Miles.
Total line per day (208 days).....	1.20
Located line per day (208 days).....	0.44
Total line per day (188 days).....	1.32
Located line per day (188 days).....	0.48

It will be noted that there were 14 men and a team of horses, and that the expense for food, etc., was \$270 per month. Counting

**Engineering-Contracting*, January, 1906.

each horse as the equivalent of a man in expense of feeding, we have a daily expense of slightly less than 60 cts. per man per day for food. That is a liberal estimate for present conditions, but on the other hand, salaries and wages are somewhat higher now than they were 15 years ago.

Another line, 227 miles long, was run in November and December of 1891, for the Saginaw & Western R. R., from Sparta to Howard City. The country was in part very rough. The timber was principally very light, with some brush. The ground was generally covered with logs and stumps. Considerable of the line was in old pine choppings. No team was provided for carrying the men to and from the work. The following was the monthly payroll:

	Per month.
Assistant engineer	\$125.00
Transitman	100.00
Leveler	100.00
Rodman	40.00
Chainman, head	45.00
Chainman, rear	30.00
Flagman	30.00
3 axemen	90.00
Cook	45.00
Total	\$605.00

The party, which was composed of 11 men, was paid for 48 work days. The actual number of days worked, however, was 36, Sundays and rainy days accounting for the other 12. The party was in camp for 42 days; on the remaining 6 days they boarded and roomed at hotels. The total cost of the field work was \$1,307.97, divided up as follows:

Payroll	\$972.00
Supplies	167.77
Board and hotel bill.....	60.25
Axes, grindstone, etc.....	16.00
Miscellaneous expenses	98.75

To the cost of the field work must be added the cost of the office work for maps, profiles and estimates. This amounted to \$219.75, making the total cost of the survey \$1,524.72. A total of 71.4 miles of line was run, of which 48.7 miles was preliminary line and 22.7 miles was located line. The actual number of days worked on the preliminary line was 25; actual number of days on located line was 11. The following table gives the average amount of line run per day worked:

	Stations.	Miles.
Preliminary line	102.8	1.947
Location	109	2.064
Average line per day.....	104.7	1.982
Average line per day out.....	78.5	1.486
Location line per (36 days).....	32.3	0.624
Location per line (48 days) out.....	25	0.473

The cost of the survey per station and mile was as follows:

	Per station.	Per mile.
Field work	\$1.09	\$57.50
Office and field work.....	1.77	67.17

As was stated previously, the party was composed of 11 men and was in camp for 42 days. The total cost of food, supplies, etc., including the cook's wages for this time, amounted to \$222.70. The cost per man per day for supplies only amounted to 26 cts.; including the wages of the cook, the cost per man per day was 49 cts.

Cost of a Railroad Re-Survey, Canada.—In a paper read before the Ontario Land Surveyors' Association, Mr. W. E. McMullen, describes a re-survey of the Canadian Pacific Ry. line in New Brunswick, and the following notes have been taken from his paper: The general scheme of the survey was to make a center line traverse and tie in right-of-way fences, lot lines, parish and county boundaries, locate the properties of the various owners along the line, run rail levels, obtain approximately the original ground line, and note the dimensions of culverts, etc. For the field work two box cars were fitted up. The one with bunks and a drawing-table, and the other with a dining-table, stove, and quarters for the cook. The party was composed of an engineer in charge, transitman and two picketmen, a draftsman, a leveler and rodman, and three chainmen, who went ahead and paint-marked one rail every hundred feet. These last could cover eight or nine miles a day without much trouble, and, after getting their work well ahead of the party, were recalled to locate right-of-way, fences, culverts, etc. The leveler would cover about $4\frac{1}{2}$ miles per day, and when he got too far ahead of the transit was recalled and ran a spare transit for a while. The transitman was paid \$75 per month and draftsman the same; leveler, \$60, and the others, most of them engineering students, \$1.35 per day. The cook got \$40 per month. The average progress of the field work was a little over two miles a day, and the average cost of the field work, exclusive of car furnishings and inclusive of wages and board, was \$14 per mile. The cost of fitting up the cars with stoves, bunks, blankets, mattresses, tables, dishes, etc., amounted to about \$150.

Cost of Two Railway Resurveys.†—The resurvey of a railway is a task which may involve little or much work, depending on the comprehensiveness of the records required. When the task is merely that of retracing alignment and locating tracks and structures the work is simple. When, however, the task comprises in addition, the topographical mapping of the line, right of way, buildings and structures and the recording of all co-ordinate information, an organization of the highest character and efficiency is absolutely necessary. In the text which follows we give from actual records the methods adopted in resurveying 581 miles of the Chicago & West Michigan Ry. and 389 miles of the Detroit, Grand Rapids & Northern Ry. These methods are not only of interest in themselves, but they are lent particular value by the figures of cost which accompany them. In studying these figures, however, it must be kept in mind that they represent wages and prices of 1893 to 1898.

**Engineering-Contracting*, Oct. 14, 1902.

†*Engineering-Contracting*, Sept. 5, 1900.

CHICAGO & WEST MICHIGAN SURVEY.

In 1893 the Chicago & West Michigan Ry. started a resurvey of its road. The object of the survey was to obtain data for the preparation of a set of maps to show in as complete and accurate a manner as possible all of the company's track, right of way, buildings and other property, and all such other information relating to these items as could be obtained. The purpose was also to obtain similar information relative to the track and property of other roads at junction points.

Field Force and Outfit.—The field party consisted of three men: the assistant engineer in charge of the work and two rodmen. They were supplied with the following outfit: one double velocipede car, a transit, two 100-ft. steel tapes, one 50-ft. steel tape, one 50-ft. cloth tape, one small hand instrument for taking fence angles, etc., an axe, a maul, a set of branding irons, a set of steel dies, a tinner's stove, a paint pot and brush, a spade, a pick and a stock of pickets. The men boarded at hotels or, when more convenient, at private houses and usually moved every 10 or 15 miles accordingly as it was convenient to get board. Very little use was made of trains to get to or from work; the party, however, generally moved by train when going to new headquarters.

Chaining the Line.—The first work was to chain the track. This was done very carefully, and one of the 100-ft. steel tapes was reserved for this work alone. Ten ($3/16$ -in. diam.) 12-in. chaining pins were used, and at every tally an 8d. nail was driven into the ballast or into a tie for reference in case a pin was lost or misplaced in the next 1,000 ft. The chain was carried in the center of the track and the half-gage was laid off from the right-hand rail at each station. For this purpose a 6-ft. picket was arranged with a lug on one end and a center mark. No corrections were made for grades or temperatures.

A paint mark was put on the flange of the right-hand rail opposite every station and at every 500 ft. a stake was driven 5 ft. to the left of the center line. These stakes were of oak, $3 \times 3 \times 30$ ins. with 8-in. points, and were purchased already sharpened. They were distributed by freight train in lots to suit the distances covered by the field party from the various headquarters. All the stakes used from any one headquarters were marked at one time: for this purpose there were provided a firepot or tinner's stove, as noted above, and a set of from 0 to 9 cast-iron branding irons fixed to a handle of round iron some 15 ins. long. Section men usually helped to deliver the stakes between station stops. The stakes were driven so as to project from 4 to 6 ins. above ground and with the branded face toward the track.

It may be noted here that this work furnished incidentally an opportunity to study the advantage of using stakes treated with some preservative from decay. The stakes placed in 1893-4 were untreated and those placed in 1896 were dipped in hot coal tar and pitch. Similar stakes used on the Detroit, Grand Rapids & Northern survey in 1896 to 1898 were treated, those used in 1896 with

"Woodline" used cold and those used in 1897-8 by dipping in hot Carbolineum. It was found upon examining in 1899 the stakes placed in 1893 that fully one-third were rotten or missing, and all of them had to be removed. It was also found that none of the treated stakes set in 1895 showed any signs of decay.

The stakes, as before stated, were spaced 500 ft. apart. At every mile a piece of T-rail 5 ft. long was set 20 ft. to the left of the center line, with the base facing the track and marked with the mile number by means of a steel stencil. Station and mile numbers were both continuous and read from the actual end of the rail at the terminal where the survey was begun.

Retracing Alignment.—The alignment was retraced by means of a transit, but not by running a continuous line. On tangents the direction was checked often enough to find all swings, by setting the transit over the gage side of the rail and taking a back sight on the rail and then reversing and sighting on the rail ahead. If any change in direction showed it was noted as an angle. When a curve was reached a point was marked in the center of the rail at or back of the point of curve, and then deflection angles were read to such station on the curve. When the transit had to be moved up the vernier was set at zero for a back sight on the last point and then the angles ahead were read on as before. When the point of tangent was reached a point was worked in the center of track between rails at or just ahead of the point of tangent; the angle was read to this and then the transit was moved up and the angle from the last rail point or chord to the tangent ahead was read. The direction of tangents was kept as azimuth, south being assumed as zero and angles recorded around by the west or clockwise.

Azimuth was determined by Polaris, stations for observations being selected so that the meridian would intersect a tangent. The angle to the tangent was then measured. An observation was taken about every 15 miles and the course of the tangents calculated from the angles measured along the center line. The two usually lacked from 0° to 0°-10' of checking, and the difference was distributed among the angles around the curves. The method of determining the true meridian from Polaris was the one in the manual issued to surveyors by the Government Land Office, and known as the hour angle method. Whenever the difference in the longitude of two observations exceeded about 6 miles the correction made necessary by the divergence of the meridians was introduced. This amount was distributed over the line by adding or subtracting from the azimuth of tangents at their ends. By reason of this a long tangent which was in reality straight would have a difference of azimuth at its two ends. The determining of the azimuth of the line at different points was intended only as a check on the transit work, but probably the course of each tangent was correct with 0°-1' or 0°-3'.

Topography.—The topography was in nearly all cases taken by measurements referred directly to the center line. All structures belonging to the permanent way, such as bridges, were recorded by plusses to each end or by a plus to the center and size. The length, size and kind of pipe or other culverts and of trestles, bridges,

open culverts and cattle guards were recorded. Right of way fences were carefully located by stations and plusses on line and by distance out at all points where any change in direction or distance out occurred. Track signs were located in the same way and usually the terms used to note them, as "Wh. Post," "Mile Board" and "Hy. Cross. Sign," indicated the use and construction in each case. Property line fences were shown by noting by stations and plusses the points at which they would intersect the center line and by measuring the angle of intersection. Highways and farm roads, highway crossings, farm crossings, gates, side drains at crossings, and ditches were all shown. The kind and make of rail and the date of rolling, with a description of joints and fastenings; the kind and condition of the ties; the kind and quality of the ballast; the kind of fence and the location and number of wires in the telegraph line were all shown and noted at the points where any change occurred. The kind of switch stand and kind and size of frog were noted. For buildings belonging to the company, the class, use, kind of foundation and point were noted. If possible, note was also made of the date of erection. Water stations, interlocking plants, etc., were usually described in detail.

Section lines, property lines and street lines were determined as accurately as possible. All monuments that could be found were located, the usual method being to produce the lines as indicated by the monuments to an intersection with the center line and record the angle with the distance measured along the monument line. For the purpose of tying the line to the village plots the field party was furnished with copies of all recorded plots, and with the aid of these sufficient tie lines were run to form a network on which the streets and lots could be plotted on the maps. Any additional information as to the company's right of way that could be found was secured. In these tie lines and also for all cross lines that intersect the center line on curves, the angle was read with the chord between the two adjacent transit points, but the plusses and distances out are from the actual center line intersection. No attempt was made to show the natural topography except in case of streams and of some very prominent ravines that intersected the line.

Mapping.—The maps were drawn on sheets of mounted egg-shell paper; the map sheets were 18 x 42 ins. and were bound in books containing about 25 to 30 miles of line. Three scales were used in mapping, 2,000 ft., 200 ft., and 50 ft. to the inch. The 2,000-ft. scale was used for an index map bound in the front of the book as a title page. On this sheet the railway was designated by a blue line on which tenth stations were numbered and mile posts shown by red lined blocks, with numbers referring to the particular large scale map (200 ft. or 50 ft.) on which the post came. The maps on the 200-ft. scale showed everything in the open country, but in cities where the same territory was covered by maps on the 50-ft. scale, much of the detail was left off in order that (1) what the company owned, (2) all recorded plots and (3) the lines to monuments in those plots might stand out clearly. As a rule, all buildings, etc., were put on and all figures

left off, the latter being confusing while outlines are not. Every fifth station was indicated by a red dot. The center line of the railway was shown by a ruled red line. Any territory shown also on the 50-ft. scale map was enclosed by a broken line in blue, with a designating number inside corresponding to the number of the special map. These special or detail sheets were inserted immediately after the general sheet referring to them. On the 50-ft. scale maps it was attempted to show everything that appeared in the note books; center lines were drawn in solid red and base lines in solid ~~black~~.

The stations on all maps were numbered from right to left. In the upper right-hand corner of each sheet was lettered the first and last station number included in that sheet and also the number of the note book and its page numbers where the notes corresponding to the map data were to be found. The number, length, total angle and degree was written near each curve. Reverse curves counted as two curves. Station numbers were written across the center line and the numerals designating angles were written on an arc connecting the two legs. Azimuths were noted at each point of curve and point of tangent.

An abstract of such deed and indexed paper for right of way represented on any sheet was written on that sheet. In this abstract the following order was followed where possible: (1) Kind of deed and number by which it is known; (2) grantor; (3) grantee; (4) date of transfer; (5) description; (6) consideration; (7) agreement, and (8) date, book and page records.

The coloring used on the maps was as follows: For fences, yellow lines; for water, blue lines; for frame structures, gamboge; for brick structures, light red; for stone structures, a neutral tint; for platforms, sidewalks, farm crossings and for iron and steel bridges, Payne's gray; for railway property, Lake red; for streets, Vandyke brown. The tinting on the 200-ft. scale maps was ruled, but on the 50-ft. scale maps only a narrow wash around the edges was used.

Time and Cost of Survey.—The resurvey described was begun in April, 1903, and was completed in October, 1905, the work in the field occupying only eight months of the year. Paying the assistant engineer in charge \$115.67 per month, rodman \$65 per month, and chainman \$60 per month, the following records of time and cost of surveying 152 miles were obtained:

	Days	Cost.
Chaining and setting stakes.....	28 $\frac{1}{4}$	\$279
Topography, taking notes.....	57 $\frac{1}{4}$	561
Running section lines and corners...	24	227
Survey of station grounds.....	28 $\frac{3}{4}$	233
Running lines to village plots.....	20 $\frac{1}{4}$	204
Total	205	\$1,564

The totals give the labor cost per mile surveyed as \$10.22, exclusive of leveling. The labor cost of leveling 127.8 miles was \$166, making the cost per mile \$1.30, and the time required for the work

was 29 days. The total cost of labor and materials for surveying 581 miles was as follows:

	Total	Per mile.
Fieldwork, on survey.....	\$ 5,238	\$ 9.01
Fieldwork, material	292	0.67
Fieldwork, setting monuments.....	899	1.55
Material, setting monuments.....	415	0.71
Office work, plotting maps.....	5,546	9.54
Office work, materials.....	448	0.77
Copying village plots at county offices.	752	1.30
Office work, copying notes, tables, etc...	1,050	1.81
Totals	\$14,738	\$25.36

A total of 509 monuments were set at a unit cost of \$1.25 for labor and 44 cts. for material.

DETROIT, GRAND RAPIDS & NORTHERN SURVEY.

The resurvey of the Detroit, Grand Rapids & Northern Ry. for 389 miles began in July, 1896, and was completed in December, 1898. The method of work was the same as that described for the Chicago & West Michigan Ry., and the wages paid were the same except that the engineer in charge received \$100 per month. The total cost of the survey and mapping was as follows:

	Total	Per mile.
Fieldwork, on survey.....	\$3,362	\$ 8.64
Fieldwork, material	437	1.25
Fieldwork, setting monuments.....	765	1.97
Materials, setting monuments.....	265	0.68
Office work, plotting maps.....	3,223	8.55
Office work, materials.....	279	0.78
Copying village plots.....	215	0.55
Office work, copying notes, tables, etc...	234	0.73
Fieldwork, running levels, 351 miles....	437	1.25
Fieldwork, plotting profiles.....	125	0.36
Totals	\$9,364	\$24.06

Cost of Railway Surveys.—In making a railway survey along the Columbia River, in open rolling country, my records show that a topographical party, consisting of 1 topographer and 2 rodmen, averaged $1\frac{1}{2}$ miles a day, taking a strip 400 ft. wide, contours 5 ft. apart. A hand-level and tape were used. In this same country a leveler and rodman could readily run 6 miles of profile levels in a day, although it was safer to count on 4 miles.

On another similar survey in southern New York state, in comparatively level country, a transitman, 3 chainmen and a stake artist, averaged 2 miles of transit line per 8 hrs. Station stakes were set every 100 ft. This same party, later, took a belt of topography 500 ft. wide, at the rate of $1\frac{1}{4}$ miles a day, setting a transit up at each station and taking telemeter readings for distances and level readings for elevation with long bubble of transit.

The cost of a preliminary railroad survey, near Lake Erie, was as follows, using stadia measurements:

Chief of party	\$ 5.00
Transitman	3.00
Recorder	3.00
5 rodmen, at \$2.....	10.00
Total salaries per day.....	\$21.00

This party ran 46 miles in 30 days, several of which were stormy, and they took a belt of topography 800 ft. wide. The cost was about \$14 a mile, or \$90 a square mile for the field work.

Using the chain method it took a party 24 days to run 45 miles.

In *Trans. Am. Soc. C. E.*, Vol. 31, p. 81, Mr. M. L. Lynch states that one mile of line a day is a fair average in partly timbered country, for preliminary work. He gives the average cost of surveys at \$60 a mile of located line.

Mr. Kenneth Allen states that in Kansas prairies he ran 312 miles of stadia line in 5.7 months, or 3.1 miles per day, a party costing as follows per day:

Transitman	\$ 6.00
Leveler	4.00
2 rodmen, at \$2.50.....	5.00
Axman	2.00
Teamster and team.....	3.00
Total per day.....	\$20.00

The cost was \$11 a mile. Bench levels were run ahead of the transit. The best day's run was 8 miles.

The Cost of Transit Lines in Heavy Timber.—In running transit lines through the dense timber of western Washington, for roads and railways, I have found that a party of 6 men (consisting of a transitman, two chainmen, two axmen and a flagman, who also served as an axman) averaged about 1,800 ft. of line run per 10 hours. It was exceptional that 2,000 ft. were averaged even for two or three days. No trees more than a foot in diameter were chopped; but the growth of great firs and cedars (occasionally one was 10 ft. in diameter), and the mass of fallen timber under foot made the advance slow. Where the timber was not so dense, it was possible to run from 3,000 to 5,000 ft. a day, setting station stakes every 100 ft. In running a traverse along a country road, where there was no tree-chopping at all, the same party would run 6 miles a day.

In running profile levels over these transit lines, a leveler and rodman would average 4,000 ft. a day in rough and densely wooded country; and 6,000 ft. in wooded country where the fallen timber did not retard walking so much. In all cases the actual time either on transit or level work averaged 8 hrs. per day, and about 2 hrs. per day were consumed in going to and from camp.

The foregoing records apply to lines aggregating several hundred miles in length, and are given partly from memory as my original detailed notes were lost in a fire.

Cost of Topographic Survey for 160-Acre Park.—In the State of Washington the author was in charge of a survey for a small city park of 160 acres. The work was done in August, 1892, with a party of 5 men, whose daily wages were as follows:

Transitman	\$ 5.00
Recorder	2.00
2 chainmen, at \$2.50.....	5.00
1 axman	3.00
Total per day.....	\$15.00

This party was engaged 26 days in field work. In addition, a draftsman and computer was engaged for 40 days reducing the notes and plotting the map to a scale of 100 ft. to the inch, contours 10 ft. apart. The cost of the survey and map was, therefore, as follows:

Field work, 26 days, at \$15.....	\$390
Office work, 40 days, at \$3.....	120
Total, 160 acres, at \$3.20.....	\$510

This is at the rate of \$2,040 per sq. mile. This high cost was due to the roughness of the ground and to the fact that about half the area was densely timbered. The area surveyed was a hill about 350 ft. high, cut up by a number of gulches. A traverse line, 2 miles long, was first run to enclose the hill, station stakes being set every 100 ft., using a tape and transit. Then 10 parallel cross-lines were run along ridges through the woods over the hill, using tape and transit. The aggregate length of these cross-lines was 3 miles. Profile levels were taken with a Y-level along all the transit lines. Contours were located by means of the stadia, the transit being set upon hubs on the transit lines. The density of the timber greatly retarded the stadia work, due to the axe work necessary. Were I to repeat this work, I should run a traverse around the area as before, chaining and leveling; then all the necessary cross-lines over the hill would be run, using the stadia. Where woods are heavy it is necessary to run such cross-lines close together. I should increase the number of axmen, and have rodmen also serve as axmen.

Cost of Topographic Survey of St. Louis.—Mr. Oliver W. Connet gives the following: The area covered by triangulation was 20 sq. miles, the average length of the sides of the triangles being $1\frac{1}{2}$ miles. About $92\frac{1}{2}$ miles of precise levels were run in duplicate at a cost of \$30 per mile, four benches per mile. The stadia method was used for topography, contours being 3 ft. apart, about 300 points being located by a party in a day. The party consisted of 1 topographer, 1 recorder, 3 stadia men, and 1 utility man. The average was 3.65 points per acre. The time of a party occupied in field work for $23\frac{1}{2}$ sq. miles was: Triangulation, 62 days; precise levels, 114 days; topography, 248 days; total, 424 days. The cost was:

Triangulation	\$ 1,812 or 11%
Precise levels	2,762 or 16%
Topography	6,080 or 36%
Office work (reduction of notes and plotting)	6,286 or 37%
Total	\$16,940 or 100%

This is equivalent to \$725 per sq. mile, or \$1.13 per acre.

The average cost of the party per day, including transportation, instruments, etc., was:

Triangulation	\$29.25
Precise levels	24.35
Topography	24.50

Cost of a Stadia Survey, Baltimore.—Mr. R. A. MacGregor, in *Trans. Am. Soc. C. E.*, Vol. 44, p. 112, gives the following on the cost of a stadia survey of the City of Baltimore, Md. The map was plotted on a scale of 200 ft. to the inch, and fences, roads, houses (with some details of houses), 5-ft. contours, wooded and cultivated areas, creeks, etc., were shown. Everything was plotted in the field. The average error of closure was 1 in 700. The average number of shots was 6,400 per sq. mile. The number of shots per day averaged 180, the maximum was 349, all the plotting and sketching being done in the field. The shots were taken and recorded by the recorder, and plotted by the draftsman, who stood nearby; the topographer in charge did the sketching. The cost of this field work alone was \$850 per sq. mile for an area of 33.3 sq. miles.

Cost of Topographic Survey, Westchester Co., N. Y.—Mr. G. L. Christian, in *Trans. Am. Soc. C. E.*, Vol. 44, p. 115, gives the cost of making a survey in July, 1896, of a 57-acre tract of land in Westchester County, N. Y. Three-fourths of the tract was wooded, with much thick underbrush. The land was much broken, having a total rise of 150 ft., with slopes of 2% to 40%. The transit lines (12,750 ft.) covered the controlling points, stakes being set every 50 ft., and profile levels taken with Y-level. From these lines, with a hand level and tape, the 5-ft. contours were located. The map was plotted on a scale of 100 ft. to the inch. The cost per acre was as follows:

Running transit lines.....	\$0.40
Running Y-levels	0.19
Contours with hand level.....	0.53
Stakes	0.07
Plotting transit lines.....	0.13
Plotting contour lines.....	0.15
Total per acre.....	\$1.47

This is at the rate of \$9.40 per sq. mile.

Cost of Topographic Survey Near Baltimore.—Mr. Kenneth Allen, in *Trans. Am. Soc. C. E.*, Vol. 44, p. 113, gives the following relative to the cost of stadia surveys made for the Baltimore Sewerage Commission:

Survey.	I.	II.	III.	IV.	V.
Contour interval	5 ft.	5-ft.	5 ft.	2.5 ft.	2.5 ft.
Scale of map.....	1"=800'	1"=800'	1"=400'	1"=200'	1"=200'
Area, square miles....	2.04	2.75	4.83	0.822	0.733
Area, timbered	47%	27%
Area, water surface...	3%	12%	18%
Area, per day, water surface	0.157	0.131	0.079	0.052	0.052
Sal. per sq. mile.....	\$54.90	\$78.00	\$140.20	\$223.61	\$256.21
Exp. per sq. mile.....	11.91	16.49	28.54	30.73	13.50
Cost per sq. mile....	\$66.81	\$94.49	\$168.74	\$254.34	\$269.71

These costs do not include mapping done in the office, but do include maps made in the field. In surveys I and V the ground had gentle slopes; in III the range of elevation was 125 ft., but in the other areas it did not exceed 40 ft. Comparing I and IV shows the increased cost where 2.5-ft. contours are located. Comparing I

and II shows the economy of reading bearings with a compass (instead of with a vernier) and setting up on alternate points which was done in survey I.

Mr. Kenneth Allen, in *Trans. Am. Soc. C. E.*, Vol. 30, p. 614, gives the following data: A stadia survey made for the Philadelphia Water Department, in 1884, covered 446 square miles and occupied 162 days field work in the Perkiomen Water Basin, in Bucks, Montgomery and Lehigh Counties. The contours were 10 ft. apart plotted on a scale of 400 ft. to the inch. All roads, buildings and timber outlines were shown. The party consisted of 1 transitman and 1 rodman; the average area covered per day taking notes in the field was 0.434 square mile; the average area covered per day plotting in the field was 0.31 square mile.

On a survey in the Connellsville coke region, a survey similar to the above, but more detailed and plotted to a scale of 800 ft. to the inch, contours 10 ft. apart, covering an area of 168 square miles, cost \$116 per square mile, including the location of farm boundaries, coal outcrops and areas, and the reduction of all previous surveys to the same scale. The cost of the field work on the topography alone was, however, only \$40 per square mile, or about one-third the total cost. The cost of engraving and publishing was about \$30 per square mile more.

Cost of Three Stadia Topographic Surveys.—Mr. F. B. Maltby, in *Jour. Assoc. Eng. Soc.*, 1896, has an article on "Methods and Results of Stadia Surveying," from which the following abstracts have been made:

A party should consist of an observer, a recorder, and 2 to 4 rodmen. A good observer in open country can locate 500 points a day for a map of 500 ft. to the inch. This means about $5\frac{1}{2}$ or 6 hrs. of actual observing, and gives an average of $1\frac{1}{2}$ shots per minute. Two men using the Colby protractor (one calling off and one plotting) plotted 216 shots per hour, as the average of $25\frac{1}{2}$ hrs.

A stadia line, 15 miles long, over which levels were run, checking on each stake, showed discrepancies between consecutive stakes as high as 0.2 ft., but the total error for the 15 miles was less than 1 ft.

The cost of stadia surveys varies widely. The topographical survey of Baltimore, for topography alone, excluding triangulation and precise levels, cost \$1.50 per acre. The scale of the map is 200 ft. per in., and all buildings, streets, alleys, etc., are located. The cost of the topography of the survey of St. Louis was 73 cts. per acre, scale of map the same, but few buildings and few street corners were located. A topographical survey of 3,000 acres, near Madison, Ill., in 1892, cost 50 cts. per acre including mapping; scale was 400 ft. per in., and all buildings, fences, railroads, etc., were located.

Several different tracts of land near St. Louis, of 100 to 200 acres, were surveyed for 20 to 40 cts. per acre. In these cases a scale of 400 ft. per in. and a 2-ft. contour interval, and only the configuration of the ground were required.

A survey of 9,500 acres in southwest Texas, in 1894, was made; 2-ft. contours; and 400 ft. per in. scale; ground was rolling and partly covered with brush; condition favorable; cost, 7 cts. per acre.

Topographical work on the Mississippi River, in 1891, cost \$26 per sq. mile; on the Missouri River, in 1895, \$31 per sq. mile, or 5 to 5½ cts. per acre. Scale was 1,000 ft. per in., contours 5 ft. apart, all buildings, roads, fences, limits of culture, etc., located. This cost includes a system of tertiary triangulation, but does not include mapping.

Cost of Surveys, Erie, Canal.—Mr. D. J. Howell gives cost of making surveys for the Mohawk Ship Canal, 90 miles along the Mohawk Valley from the Hudson River westward to Herkimer. The work was done by stadia parties, consisting of 1 chief, 1 observer, 1 recorder and 4 rodmen. The area mapped was 47,400 acres, of which 6,600 are river. The average cost was 86 cts. per acre, including soundings of the river, field and office work, but excluding test pits and borings. Contours were 2 ft. apart; map scale 1 in 2,500. A cross-country survey, 25 miles long, embracing 7,400 acres (no villages or cities), cost 27 cts. per acre for the field notes and the reduction of the notes ready for plotting. The cost of the plotting was estimated to be about 23 cts. per acre more, making the total cost about 50 cts. per acre. The men were well trained and the weather was favorable on this 25-mile stretch.

Mr. William B. Landreth, in Trans. Am. Soc. C. E., Vol. 44, p. 92, discusses the methods and cost of stadia topographic surveys made to determine the location of reservoirs and conduit lines for the Rome level of the Deep Waterway on the Oswego-Mohawk-Hudson Route. The surveys were made between Aug. 1, 1898, and June 1, 1899, scarcely any time being lost from bad weather. A party consisted of 1 engineer in charge, 1 transitman, 1 recorder, 3 or more stadia rodmen, 3 or more axmen, 1 draughtsman, and 1 computer. Each rodman was given a particular class of work, one following streams, another taking roads, another woods, and so on. When convenient all rodmen kept on the same side of the transit. Contour intervals were 10 ft. on the Salmon River and the Black River surveys, and 5 ft. on the Fish Creek line. At the close of each day the field party reduced the stadia notes. The scale of the Salmon River and the Black River maps was 1:10,000, and of the Fish Creek map, 1:5,000. About 65% of the Salmon River area is covered with small second growth timber and swamps. The country is rough. The Black River Valley, between the villages of Carthage and Lyons Falls was surveyed up to the 790-ft. contour. Only 26% of the area is wooded, and the country is not very rough. The Fish Creek Valley, from 2 miles above Williamstown, to 2 miles below Taberg, a distance of 21 miles, was surveyed, the survey covering the valley and a portion of the side slopes to an elevation of 75 ft. above the creek. The ground was mostly grazing and farm land, 40% of which was timbered. The cost of the three surveys, including finished maps, traveling expenses, etc., was as follows:

	Salmon River.	Black River.	Fish Creek.
Area, square mile.....	15	85	19
Set-ups	771	609	451
Shots	3,838	11,166	11,716
Square miles per day.....	0.32	1.81	0.45
Field work per square mile.....	\$86.00	\$16.50	\$54.00
Map work per square mile.....	14.00	7.00	25.00
Total per square mile.....	\$80.00	\$23.50	\$79.00

Nota.—The cost of the base line surveys for the Salmon River and Fish Creek work, and for one-third of the Black River, is not included in the costs above given; the costs include no leveling, but only the stadia field work and mapping, excepting on the Black River where base line and leveling costs for two-thirds the territory are included.

Cost of U. S. Deep Waterways Survey, N. Y.—Mr. A. J. Hilmea, in *Trans. Am. Soc. C. E.*, Vol. 44, p. 105, gives the following data on the U. S. Deep Waterways Surveys for a 30-ft. canal along the Oswego and Mohawk Rivers, a distance of 91 miles. A sufficient number of stadia readings was taken to develop 3-ft. contours. About 83% of the area was mapped on a scale of 1:5,000; the other 17%, on a scale of 1:2,500. There were 12 sq. miles of soundings made in Oswego Harbor and Oneida Lake, and plotted; and an area of about 78 sq. miles of Oneida Lake and Oswego Harbor was determined by triangulation. There were, besides, 121 sq. miles of land topography taken. All buildings, roads, railroads, property lines, streams, orchards, swamps, etc., were located. A stadia party consisted of 1 instrumentman, 1 recorder and 3 rodmen, with sometimes 1 laborer for cutting brush or rowing a boat. Each night the party reduced the stadia notes and calculated the co-ordinates. The error of closures was readily kept within 1 in 700; and errors in elevation seldom exceeded 1 ft., being usually less than 0.5 ft. Sights 2,000 ft. long were often taken. Charts were found to be much better than tables for stadia reductions. The work was begun Oct. 23, 1897, and finished Nov. 5, 1898. In no month were more than 5 days lost on account of bad weather. The average number of readings was 1,440 per sq. mile. The minimum average area covered per day by one party on a single piece of work was 0.053 sq. mile. The maximum was 0.357 sq. mile. The average for the whole survey was 0.123 sq. mile per party per day. The cost was as follows per sq. mile:

Fieldwork	\$179
Mapping	101
Total per sq. mile.....	\$280

This is exclusive of swamps and lakes not sounded.

Cost of Government Topographic Surveys.—Mr. Marcus Baker, in *Trans. Am. Soc. C. E.*, Vol. 30, p. 612, gives the cost of Government topographic surveys in many European countries, to which the reader is referred. The U. S. Geological Survey of New Jersey was begun in 1877 and finished in 1887, covering an area of 7,394 square miles, with contours 10 and 20 ft. apart. The cost was \$6.93 per square mile, which includes all expenses in producing a map ready

for the engraver. The engraved map is on a scale of about 1 mile per inch. A similar survey of Massachusetts, made 1884-1888, contour interval 20 ft., cost \$13 per sq. mile. A similar survey of Rhode Island, made 1888-1889, cost \$9 per sq. mile. A similar survey of Connecticut, 5,004 sq. miles, made 1889-1890, on a scale of 1 mile per inch, 20-ft. contours, cost \$9.80 per sq. mile for map ready for engraver.

A topographic map of the banks of the Mississippi River, from Cairo to the Gulf of Mexico, was completed by the Government in 1884, at a cost of \$51 per sq. mile for 1,954 sq. miles of land and water surface. The manuscript map was on a scale of 1:10,000, embracing the river and a strip of land $\frac{1}{2}$ mile wide on each side. The river was carefully sounded.

Mr. Baker gives estimates of the cost of surveys made by the Coast Survey, but these estimates are strongly disputed, moreover they are of minor value to engineers in general practice, so the reader is referred to the Transactions for the data.

The N. Y. State Engineer's Report, 1897, gives the cost of topographical surveys, for the Dept. of the U. S. Geol. Survey, as follows per square mile, contours 20 ft. apart, and map on a scale of about 1 mile to the inch:

	Sq. mile.
Triangulating (1,370 sq. miles).....	\$2 00
Topography	8.70
Office work	0.60
	<hr/> \$11.30

The total cost of 15,118 sq. miles, for field and office work, had been \$11.06 per sq. mile. A table giving the cost of 2,200 sq. miles shows a range of \$4.35 to \$25 per sq. mile, the average being \$10.05 for field and office work, of which \$8.43 was the cost of field work. The cost of office work ranged from \$1.15 to \$4.05 per sq. mile, and averaged \$1.62.

Cost of Triangulation and Plane Table Surveys.*—During the spring of 1908 a triangulation system consisting of 48 signals and controlling about 150 square miles was installed on the Grand Valley Project (U. S. Reclamation Service), and during the field season of the same year a plane table survey of approximately 127 square miles was made and maps prepared on a scale of 1 in. to 1,000 ft. with 10-ft. contour intervals. A careful record of expenditures was kept and the itemized costs are shown below.

In the triangulation survey the signals consisted of 2 by 4-in. posts 14 ft. high, erected over pieces of $\frac{3}{4}$ -in. gas pipe driven from 18 to 24 ins. in the ground and held erect by three guy wires to each post. The signals were arranged $2\frac{1}{2}$ miles apart and where stations were required more frequently or section ties were required outside of the area mapped the charge for such work was made against the topographic mapping. The costs of triangulation survey shown include the cost of measuring base lines and of making Polaris observations. No camp was established, and subsistence was obtained at hotels and farm houses in the vicinity.

*Engineering-Contracting, May 26, 1909.

COST OF TRIANGULATION SURVEY, GRAND VALLEY PROJECT.

Distribution.	Average time per sq. mile, days.	Rate per day.	Cost per sq. mile.
Transitman	0.11	\$7.50	\$0.80
Transitman14	3.33	.46
Office engineer05	3.00	.15
Recorder06	3.00	.18
Flagman25	2.25	.56
Computer06	2.25	.12
Draftsman01	2.25	.02
Hired horses08	.50	.04
Government horses (depreciation) ..	.40	.25	.10
Depreciation of equipment02
Travel06
Subsistence29
Supplies, miscellaneous18
Supplies, stakes and monuments45
Supplies, repairs02
Supplies forage22

Total cost per square mile..... \$3.63

In the plane table survey the field party usually consisted of 1 plane table man, 1 recorder and 2 rodmen, but at times a driver was necessary for teams used by level and topographic parties. The camp teamster hauled the supplies necessary, but the men furnished their own subsistence by organizing a club. The cost of hay was \$15 per ton and of oats \$1.90 per hundred weight. The area mapped was fairly rough on the average, but the cost was quite variable. On level mesas the cost was as low as \$18 per sq. mile, but where the area mapped consisted of small fruit farms with numerous buildings, roads, fences and irrigation and waste ditches, the cost ran as high as \$75 to \$80 per sq. mile.

COST OF PLANE TABLE TOPOGRAPHIC SURVEY, GRAND VALLEY PROJECT.

Distribution.	Average time per sq. mile, days.	Rate per day.	Cost per sq. mile.
Project office expenses	\$1.63

Traveling expenses for field party02
Subsistence for field parties remote from camp41

Total cost per square mile..... \$57.70

Cost of Topographical Survey, Texas.*—The survey covered about 300 acres of rolling hills near San Antonio, Tex., the range of elevations being something over 100 ft. The ground was heavily wooded with mesquite brush. Three roads in each direction which had been previously staked and cleared, provided a skeleton for horizontal control. Levels were run from a distance of two miles and bench marks established at intervals of one-third of a mile along the roads, the profiles of the latter being taken simultaneously. The details were then filled in by random stadia lines, run by compass and with short courses in such a manner as to avoid clearing. No permanent marks were used at set up points and only the alternate points were occupied by the instrument. The whole survey was made by a party consisting of instrumentman and rodman. Five-foot contours were obtained and the tract was mapped on a scale of 200 ft. to the inch.

The itemized cost of the survey and mapping was as follows:

<i>Field work:</i>	Total.	Per acre.
Party of two, 7 days, at \$7.20.....	\$50.40	
Labor extra	2.00	
Total	\$52.40	\$0.058
<i>Office work:</i>		
Platting and mapping, 1 man 10 days.....	\$35.00	
Office expenses and materials.....	5.60	
Total	\$40.60	\$0.045
Grand total	\$93.00	\$0.103

For the above information we are indebted to Mr. Terrell Bartlett, C. E.

Cost of Two Small Surveying Jobs.†—The first job consisted of a transit traverse up Town and Hanging Kettle Creeks in Clay County, Miss., the work being done in November, 1907. A summary of the work is as follows:

Number courses Town Creek.....	34
Total distance	1.97 miles (10,415.4 ft.)
Number courses Hanging Kettle Creek.....	19
Total distance	1.26 miles (6,629.3 ft.)
Number of courses in both creeks.....	53
Distance, both creeks.....	3.23 miles (17,044 ft.)
Average course	321.7 ft.

In the field work $3\frac{1}{4}$ days were spent; while the office work, computing and mapping was 6 days. The working day was 9 hours. The cost of the field work was as follows:

Instrument man, at \$5.....	\$17.50
Two chainmen, at \$1.....	7.00
Two rodmen, at \$1.....	7.00
One axman, at \$1.....	3.50
Total, $3\frac{1}{4}$ days.....	\$35.00

**Engineering-Contracting*, Nov. 11, 1908.

†*Engineering-Contracting*, April 23, 1908.

The office work cost \$30; a draftsman and computer at \$5 being employed for 6 days. The total cost was, therefore, \$65.00, and the cost per mile was \$20.12. The 1/16 section, ¼ section and section lines had been run across creeks, and ties were made to all such lines. All lines were run with transit and steel tape and all angles and lines checked before areas were computed. The map shows the acreage on each side of center line of creek in each 1/16 section (40 acres) crossed. The traverse was made on one bank, the creek being too deep to cross. The country was flat with scattering woods and bushes. The second job consisted of the survey of a convict farm in Mississippi, for a lumber company, the work being done during January, 1908; a summary of the work is as follows:

Cultivated land:

Number cuts	53	
Smallest acreage per cent.....	5	acres
Largest acreage per cent.....	16.54	acres
Total acreage	414.77	acres
Average acreage per cut.....	7.16	acres

The time in the field was 3½ days, and the time in office, computing and mapping, was 5 days; an 8-hour day was worked. The cost of the field work was as follows:

Surveyor, at \$5.....	\$17.50
Four helpers, at \$1.....	14.00

Total, 3½ days.....	\$31.50

The office work cost \$25, a draftsman being employed for 5 days at \$5 per day. The total cost was, therefore, \$56.50, or 13.5 cts. per acre. For the above information we are indebted to Mr. Charles L. Wood, C. E.

Cost of a Level Survey for a Drainage Plan.*—In August, 1904, the U. S. Department of Agriculture had a level survey made in Clay and Yankton Counties, South Dakota, for the purpose of developing a plan for the drainage of the bottom lands of the Missouri River in those counties. A description of the manner in which this survey was made was given in the Annual Report of Irrigation and Drainage Investigations of U. S. Department of Agriculture and is reproduced herewith.

The first step was to collect such information concerning the land in question as could be obtained from the county records. Convenient plats for field use were made upon land office township blanks on a scale of 2 ins. to the mile. Upon these were traced all land office data and such roads, ditches, and sloughs as were shown on the county maps. A day was then spent in making a general reconnaissance by driving over the area, in order to become somewhat familiar with its general topography. In this reconnaissance it was seen that the section lines could be easily followed, as

**Engineering-Contracting*, Sept. 12, 1906.

where they were not marked by highways there were fences or turning rows located on them, and nearly all the one-quarter and one-sixteenth section lines could be approximately located on the ground by fence or field lines.

From the reconnaissance and the field plots it was found that field measurements could be obviated by using land lines for locations, and all additional data necessary could be obtained by running levels. The plan decided on and carried out consisted in running levels along parallel north and south section lines two miles apart, extending from the ridge which marks the high-water bank of the Missouri River to the foot of the bluff. A permanent bench mark of the Missouri River Commission survey furnished the datum for the levels. Levels were recorded at each one-quarter mile along the lines surveyed, the instrument being set midway between the one-quarter mile turning points. Turning points were taken on short wooden pegs driven to the natural surface of the ground. A target rod was used and read by both levelman and rodman.

A light two-horse rig, with driver, was kept on the line and used to convey the rodman from one turning point to another. As the rodman moved one-quarter mile at a time and there was usually a good road, there was a considerable saving of time in the use of the rig, which was also used for conveying the party to and from work and for carrying water, lunch, and such survey stakes as were needed.

From five to ten miles of level lines were run per day. The growth of high grass and weeds often retarded the work. The number of side shots which were necessary to secure desired data also cut down the days' run. Side lines were also run to the lowest points in sloughs or depressions one mile each side of the main line. Where there was water in the sloughs the elevation of the water surface was taken and the depth found by sounding from a boat or wading. The level of the surface of the water of both Missouri and James Rivers was also obtained. The high-water marks were also obtained from points located by residents, and the low-water marks were determined from the plots of the Missouri River Commission. Bench marks were established at nearly all section corners and were made by driving 30-penny spikes into corner fence posts or telephone poles at the surface of the ground, a blaze being made about 4 ft. above the spike and the elevation marked upon it. Each night the elevations were recorded in their proper locations upon the field plots.

After the completion of the level work, the line between the cultivated and wet land was sketched upon the field maps by personal inspection. After the data had all been collected and platted the interior watershed boundaries and lines of proposed ditches were located on the field maps. A corrected map on a scale of one mile to one inch was afterwards made up from the field maps. The cost of this survey (32 miles of levels) was as follows:

Survey:	Per mile.
Engineer, leveling, at \$6 per day.....	\$1.06
Engineer, special field examinations, at \$6 per day...	0.40
Rodman, at \$1.75 per day.....	0.21
Livery hire, team and driver, at \$2 per day.....	0.73
Railway fare	0.03
Total cost of survey.....	\$2.53
Plans:	
Engineer, office work, at \$6 per day.....	\$0.82
Drafting supplies	0.916
Total cost of plans.....	\$0.896
Total cost of survey and plans.....	\$3.43

Regarding this preliminary survey, it should be said that only sufficient work was done to furnish the information required for developing a general plan, yet all levels are accurate and are connected with and checked upon Government river survey bench marks. A list and description of bench marks, which were fixed at each section corner of the surveyed lines, accompany the report and map which were filed with the auditor of Clay County, the expense of which is not included in the above memorandum. The survey was inexpensive, yet sufficiently full for forming a comprehensive plan for the drainage of 70,000 acres of land, and established a sufficient number of points from which future surveys for detail and construction work can be made whenever required.

Cost of Sounding Through Ice.—Mr. Joseph Ripley gives the following relative to the use of an ice boring machine, operated by bevel gear, for boring 3-in. holes through ice. Before the use of this machine, holes were chopped by axes at a cost of about 3 cts. per hole through 2 ft. of ice. With the machine, operated by two men, the average time was less than $\frac{1}{4}$ min. per hole, through 26 ins. of ice, overlaid by 2 ft. of snow, including all delays. The time of actual boring was about 8 seconds per hole. The sounding party consisted of 1 chief, recording soundings, 2 men sounding, 6 men operating three boring machines, 2 men moving tag lines and marking places for holes, 3 men shoveling away snow after holes were bored, 1 gage observer and 1 cook. Such a party averaged 2,000 holes per day of 8 hrs. at a cost of \$1,000 per month, the working day being 8 hrs. With 25 working days in a month, the cost is $1\frac{1}{4}$ cts. per hole.

In U. S. Eng. Report, 1903, Vol. 10, Part 2, p. 1296, the following is given:

An ice boring machine will bore a $2\frac{1}{2}$ -in. hole through 2 ft. of solid ice in 5 secs. A party can take 300 soundings per hr. through ice 2 ft. thick, in water 23 ft. deep, holes spaced 10 ft. x 50 ft. The best record for 8 hrs. was 2,749 soundings, ice being 12 ins. thick. The cost of soundings was 3 cts. each for field work, including locating the holes.

SECTION XV.

MISCELLANEOUS COST DATA.

Prices of Materials, Supplies and Plant.—Prices are subject to such fluctuation that I prefer to prepare a complete schedule annually, which is published in *Engineering-Contracting*, the first issue in April of each year. Rates of wages of different classes of workmen in different parts of America are also given in that issue.

The Cost of Fences.—A barbed wire fence was built under the following specifications:

"Posts to be oak or tamarack, 5 ins. diameter and 3½ ft. long, spaced 15½ ft. apart, c. to c., and set 3½ ft. deep in the ground. The height of fence to be 4 ft. 9 ins., formed of four lines of 4-barb wire, spaced 12, 14, 15 and 16 ins. apart measured from the ground up."

	Per mile.
350 posts, including braces, at 10 cts.....	\$ 35.00
1,500 lbs. 4-point barbed wire, at 5 cts.....	75.00
40 lbs. staples, at 5 cts.....	2.00
Labor	43.00
Total	<hr/> \$155.00

This 10 cts. per post was a very low price, due to the fact that posts were cut from trees near the work. Posts are frequently 5 to 10 cts. per lin. ft. of post, where they are imported by rail.

Where rail fences are built, the posts are usually spaced 8 ft. apart c. to c., and set at least 3 ft. deep. The fencing specified by the Mass. Highway Commission consists of cedar or chestnut posts, not less than 6 ins. diam. and 6½ ft. long, set 3 ft. in the ground, and spaced 8 ft. c. to c., bark peeled off. A top rail, 4 x 4 ins., and a side rail, 2 x 6 ins., are specified to be of dressed spruce; and both rails are notched into the posts and spiked. The fence is painted with one coat of white lead and oil. The usual contract price for such a fence in Massachusetts is 15 cts. per lin. ft., or \$890 per mile. There are 660 posts, and 12,300 ft. B. M. of spruce per mile.

The wire fences of the Louisville & Nashville Ry. have posts 7 ft. long, with seven wires spaced 4, 4, 6, 8, 10, 12 and 12 ins. from the ground up. For one mile of fencing the following materials and labor are required:

	Per mile.
3 barbed hog wires (7.7 lbs. per 100 ft.).....	1,318 lbs.
2 barbed cattle wires (7.14 lbs. per 100 ft.)..	754 lbs.
2 plain ribbon wires (6.66 lbs. per 100 ft.)..	704 lbs.
Total wire per mile.....	2,676 lbs.
Staples	49 lbs.
Posts, 10 ft. apart.....	528
Bracing, 1 x 4-in. yellow pine, ft. B. M.....	446
Labor	\$105

In soft soil a good workman, using an 8-in. post hole digger, will dig 100 post holes, 3 ft. deep, per day of 10 hrs.

Cost of Barbed Wire Fences.—The practice in spacing posts is variable, sometimes being 15 ft. centers, sometimes 24 ft. Farmers usually space fence posts a rod apart (16½ ft.). When the posts are spaced 20 ft. apart it is customary to support the wires between the posts by means of two wooden slats or wire stays, each 4 ft. long, and spaced about 7 ft. apart. These slats or stays prevent animals from spreading the fence wires apart in their efforts to get between them.

Bill of Material.—The standard fence used on the O. R. & N. has posts 7 ft. long, 20 ft. c. to c., and bedded 28 ins. in the ground. The first wire is 18 ins. above the ground and the rest are 12 ins. apart, except the space between the upper two, which is 14 ins. The bill of material is as follows per mile of fence:

265 posts, 7 x 7-in. x 7-ft., split cedar.
530 slats, 1 x 2-in. x 4-ft. fir.
21,120 lin. ft., or 1,410 lbs., two-point galvanized cattle wire.
16 lbs. staples, 1½-in., No. 9 polished.
26 lbs. staples, 1½-in., No. 9.

The following is a bill of materials and their estimated cost (not including labor) for the standard "second class fence" on the N. P., per mile:

1,340 lbs. (21,120 lin. ft.) galv. barb wire, at 2¼ cts.....	\$30.15
280 lbs. No. 7 galv. wire stays (675 stays, 4 ft. long), at 2.8 cts.	7.84
16 lbs. 2-in. galv. wire staples (950 staples), at 2.35 cts..	6.33
2,800 galv. anchor fence clamps, at 80 cts. per M.....	2.24
10 diagonal braces, 4 x 4 in. x 12 ft., 160 ft. B. M., at \$15..	2.40
325 cedar posts (6-in.), 7 ft. long, at 10 cts.....	21.50
6 lbs. 60d nails, at 2.25 cts.....	0.14
1 Eureka tubular gate, \$4.....	4.00
Total materials	\$63.45

For the last ten years the contract price for the labor of building such fences as this has not varied much from \$75 a mile in the far West.

We shall now give the actual cost of a number of jobs of fence work on a western railway, showing the range of costs:

Cost of a Seven-Mile Fence.—This fence was 7 miles long, built

*Engineering-Contracting, Aug. 21, 1907.

on ground that was rather rocky, making the cost of digging post holes quite high. The cost of the fence was as follows per mile:

Materials:	
1,200 lbs. barb wire, at 3.65 cts.....	\$ 34.45
400 lbs. fence stays (100), at 2.75 cts.....	11.00
90 lbs. fence clamps (3,900), at 6 cts.....	6.40
16 staples (1,890), at 2.70 cts.....	.43
352 posts (16 ft. c. to c.), at 11 cts.....	38.72
12 lbs. 40d nails, at 2.25 cts.....	.27
Total	\$ 90.27
Labor: Loading and Moving:	
2 hrs. foreman, at 25 cts.....	.75
16 hrs. laborers, at 15 cts.....	2.40
Total	\$ 3.15
Removing Brush:	
1 hr. foreman, at 25 cts.....	.25
39 hrs. laborers, at 15 cts.....	4.50
Total	\$ 4.75
Distributing Fence Material:	
2 hrs. foreman, at 25 cts.....	.75
10 hrs. laborer, at 15 cts.....	1.50
Total	\$ 2.25
Building Fences:	
32 hrs. foreman, at 25 cts.....	8.00
240 hrs. laborer, at 15 cts.....	36.00
Total	\$ 44.00
Grand total labor	\$ 55.65
Cost of labor and materials	\$145.92

It will be noted that the cost of moving the gang of men once on this job was \$3.15 per mile of fence, or \$22 for this one move, in lost time of men. Such losses as this should not be forgotten, especially in estimating the cost of small jobs.

Cost of a 2,000-Ft. Fence.—This was a short fence with posts 16 ft. apart, 4 wires to the post. The exact length of the fence was 1,932 ft., or 120 panels of 16 ft., exclusive of 2 gates. There were 4 posts used for the gates and 8 posts used for braces. The cost of this 1,932-ft. fence was as follows:

Material:	
129 cedar posts, 7 ft., at 7 cts.....	\$ 9.03
7,755 ft. barbed wire, 426 lbs., at 2 cts.....	8.52
600 fence staples, 6½ lbs., at 1.75 cts.....	.11
260 stays (4 ft.), 122 lbs., at 3.15 cts.....	3.86
1,440 fence clamps, 36.6 lbs., at 5.25 cts.....	1.89
Freight on posts.....	2.00
Total for 1,932 ft.	\$25.41
Two Gates:	
4 cedar posts (7 ft.), at 7 cts.....	.28
12 pcs. 1 x 6-in. x 18-ft. = 96 ft. B. M., at \$15....	1.44
4 lbs. 10d nails, at 2.82.....	.11
Total for 2 gates	\$ 1.83
Labor:	
2.6 days foreman, at \$2.50.....	\$ 6.50
7.3 days laborers, at \$1.50.....	11.70
Total labor	\$18.20

Excluding the gates, the cost of the materials was \$49.40 per mile, and the cost of the labor was \$49.70 per mile, or a total of \$119.10 per mile.

Cost of a 2,000-Ft. Fence.—This fence was of the same design as the one just described, the actual length being 2,974 ft.

The materials cost:

2,154 lbs. barb wire, at 2.75 cts.....	\$ 59.45
449 lbs. fence stays, at 2.75 cts.....	17.85
149 lbs. fence clamps, at 5.95 cts.....	8.87
26 lbs. fence staples, at 2.70 cts.....	.70
577 posts, at 11 cts.....	63.47
15 lbs. 40d nails, at 2.25 cts.....	.54
1 lb. 10d nails, at 2.20 cts.....	.02
2 lbs. 5d nails, at 2.25 cts.....	.05
24 pcs. 1" x 6'-16' 192', at \$8.50.....	1.62

Total cost of material.....\$152.38

This makes a cost of \$89.63 per mile of fence, including farm gates, there being 4 such gates in the 2,000 ft. An additional cost was 32 posts used for anchoring and for braces, the 15 lbs. of 40d. were also used on the anchors and braces. All the fence material had to be hauled from one to two miles on push cars by the crew to distribute it, and some brush had to be cleared away to build the fence. This and the other labor costs were:

Distributing Material for Fence:

Foreman, 7 days, at \$65.....	\$ 1.52
Laborers, 9 days, at \$1.50.....	13.50

Clearing Brush to Build Fence:

Laborer, 1 day, at \$1.50.....	1.50
--------------------------------	------

Building New Fence:

Foreman, 33 days, at \$65.....	7.15
Laborers, 37.3 days, at \$1.50.....	15.95

Putting Up Farm Gate:

Laborers, 2 days, at \$1.50.....	3.00
----------------------------------	------

Total labor.....\$82.62

A cost per mile of \$43.60, making a total cost for materials and labor of \$138.23.

Cost of a 2,540-Ft. Fence.—This fence was of the same design as those previously given posts 16 ft. apart, with 4 wires. The fence was exactly half a mile long, but the costs have been reduced to the cost per mile for convenience of comparison.

Materials: Per mile.

21,360 ft. barb wire, 1,282 lbs., at 2.65 cts....	\$ 33.98
978 fence stays, 394 lbs., at 2.75 cts.....	10.84
3,912 fence clamps, 98 lbs., at 5.95 cts.....	5.82
1,304 fence staples, 18 lbs., at 2.70 cts.....	.48
330 fence posts, at 11 cts.....	36.30

Total materials per mile.....\$ 87.42

Labor: Distributing Fence Material:

4 days labor, at \$1.50.....	\$ 6.00
------------------------------	---------

Erecting Fence:

2 days foreman, at \$2.50.....	5.00
20 days labor, at \$1.50.....	30.00

Total labor per mile.....\$ 41.00

Total material and labor.....\$128.42

Labor Costs on Four Different Fences.—Having given the costs of materials and labor on several fences, we shall now omit the material item and give only the labor costs on fences, all of which had posts spaced 16 ft. apart, and 4 wires to the post. The first of these was 2,200 ft. long and the labor of erecting it cost at the following rate per mile:

<i>Hauling Out Fence Material:</i>	Per mile.
1.2 days foreman, at \$2.50.....	\$ 3.00
12 days laborer, at \$1.50.....	18.00
Total	\$21.00
<i>Building Fence:</i>	
1.4 days foreman, at \$2.50.....	\$ 3.50
16.8 days laborer, at \$1.50.....	25.20
Total	\$28.70
Grand total	\$49.70

This did not include \$9 of lost time moving the gang from another job to this one.

The next job was the building of a fence 2,600 ft. long. The ground was rocky, making it necessary to anchor most of the posts. The labor cost at the following rate per mile:

<i>Clearing Brush:</i>	Per mile.
2 days labor, at \$2.....	\$ 4.00
<i>Building Fence:</i>	
2 days foreman, at \$3.....	\$ 6.00
24 days laborer, at \$2.....	48.00
Total	\$78.00

In addition it cost \$18 for the lost time of moving the men from another job to this one. Two farm gates were erected, and the cost of each was:

1 farm gate	\$0.90
2 posts for gate, at 10 cts.....	0.20
Labor placing gate.....	2.00
Total	\$3.10

The next job was a fence 3,300 ft. long. The labor cost at the following rate per mile:

<i>Distributing Fence Material:</i>	Per mile.
1.1 day foreman, at \$3.....	\$ 3.30
13.8 days laborer, at \$1.50.....	20.70
Total	\$24.00
<i>Clearing Brush:</i>	
2.4 days laborer, at \$1.50.....	\$ 3.60
<i>Building Fence:</i>	
1.1 day foreman, at \$3.....	3.30
21.8 days laborer, at \$1.50.....	32.70
Total	\$36.00
Grand total labor.....	\$63.60

In addition to this, the lost time moving to this job amounts to \$10.

The next job was a fence 5,700 ft. long, and the labor cost at the following rate per mile:

<i>Distributing Fence Material:</i>	<i>Per mile.</i>
3.8 days laborer, at \$1.50.....	\$ 5.70
<i>Building Fence:</i>	
1.8 days foreman, at \$3.....	5.40
16.6 days laborer at \$1.50.....	24.90
<i>Loading Barb Wire on Car:</i>	
0.5 day foreman, at \$2.50.....	1.25
2.5 days laborer, at \$1.25.....	3.13
Grand total labor.....	\$40.38

Fence 5,000 Ft. Long.—The posts in this example were 30 ft. center to center. One gate was built. The material cost:

254 fence posts, 4.5 cts.....	\$11.43
1,215 lbs. No. 9 galv. iron wire, 3 cts.....	36.45
285 lbs. fence stays, 3.75.....	10.69
96 lbs. fence clamps, 6.25 cts.....	6.00
18 lbs. fence staples, 2.20 cts.....	3.96
1 lb. 40d nails, 1.5 cts.....	.02
3 pcs. 2" x 6"-16' 48', \$11.50.....	.55
	\$52.24

Labor cost as follows:

Foreman, 6 days, at \$48.75.....	\$ 292.50
Laborers, 18 days, at \$1.50.....	27.00
	\$319.50

Making a cost per mile for material of \$52.24, for labor \$319.50, and a total cost \$371.74. This includes one gate.

Cost of a Wire Fence.—Mr. F. W. Doolittle gives the following data on 6,650 ft. of 4-wire fence, posts spaced 16 ft., as built recently about the top works of a coal mine near Denver, Colo. The work was done by regular employees on idle days during the summer, which accounts for lack of uniformity in day wages, and also for a comparatively high labor cost. No special item of superintendence is charged as the force was so small that the overseer also made a hand. The cost of the 6,650 ft. was:

<i>Labor:</i>				
Surveying line, 3 days, at \$2.50.....	\$	7.50		
Digging holes, 14 days, at various.....		26.00		
Setting posts, 7½ days, at \$2.50.....		18.75		
Stretching wire, 8½ days, at various.....		23.50		
Total labor	\$	75.75		
<i>Materials:</i>	<i>Cost.</i>	<i>Freight.</i>	<i>Hauling.</i>	<i>Total.</i>
Posts	\$75.00	\$25.00	\$6.50	\$106.50
Wire	56.42	2.59	1.25	60.26
Staples	3.52	(Included in wire)		3.52
Total materials.....				\$170.28

An 8-hr. day was worked. The item, digging holes, includes 1 day, man and team, at \$1.50, and the item setting posts includes 1½ days at \$2.50, setting braces. The holes were dug with post auger to a depth of about 12 ins., where the ground was too hard for further progress. The holes were then filled with water, after which they could be deepened to from 20 ins. to 24 ins., or as far as the earth had been dampened.

Wires were stretched as follows: The reel was mounted on back of wagon box and several hundred feet of wire reeled off. The back end of wagon was then raised off the ground and a post placed between the rear axle and the ground to prevent the wagon running back. The rear wheel was used as a tightener by taking a couple of turns of wire about hub and turning wheel around by hand, or by a bar through spokes against wagon bed.

A comparative cost per mile of the above fence and the fence at San Antonio, Tex., described by Mr. Tyrrell Bartlett, in our Nov. 11 issue is as follows:

	San Antonio. Per mile.	Denver. Per mile.
Materials:		
Posts	\$ 56.80	\$ 85.20
Wire and staples.....	48.20	50.80
Total materials	\$104.50	\$136.00
Labor:		
Digging holes	\$ 40.40	\$ 28.80
Setting posts, tamping posts, stringing wire.....	35.50	33.80
Running line.....	6.00
Total labor	\$ 75.90	\$ 68.60
Grand total	\$180.40	\$204.60

The chief difference lies in cost of posts, those used near Denver costing 50% more than those used at San Antonio. At San Antonio 5-in. cedar posts, set 30 ins. deep and 15 ft. on centers, were used, with four strands of wire. The labor on the holes was paid by the hole according as each was in earth, part in, or all in adobe. Other labor, \$1.50 per day.

Cost of Digging Post Holes for a Fence.*—In building the levees along the Mississippi River to retain the waters within its banks, fences are erected on both the land and river side. The price paid for this work is included in that for excavation.

The fences are built with posts 6 ins. square, 7½ ft. long, 2½ ft. being in the ground. These posts are of oak, mulberry, black locust or sassafras, cut in the local timber lands. They are spaced 12 ft. apart. Four galvanized barbed wires are stretched and attached to the posts.

Along the Mississippi at present foremen are paid \$100 per month and board, while laborers are receiving \$1.75 for a 12-hr. day. The materials and labor give a cost of a single line of fence per mile of \$125, which is quite low.

**Engineering-Contracting*, Aug. 28, 1907.

The post holes are dug with post hole augers, the holes being 6 ins. in diameter and $2\frac{1}{2}$ ft. deep. In the soil that occurs along the river, one man with a 6-in. auger, working 12 hrs., will dig on an average 100 holes. This means a cost of 1½ cts. for labor for digging a hole, and, as there are 440 holes to a mile of fence, the cost of digging the holes per mile will aggregate \$7.70.

From each hole is excavated $\frac{1}{2}$ cu. ft. of earth, and, with a 6-in. auger digging to a depth of $2\frac{1}{2}$ ft., the cost of excavating a cubic yard of earth is \$4½ cts.

Assuming that for a 10-hr. day a man would do proportionally the same amount of work, with wages at \$1.50 per diem, we then have 84 holes dug in a day, making a cost of 1.8 cts. per hole, and cost per mile of \$7.92. With the national government enforcing the 8-hr. law on the levee construction that is to be done under United States engineers, the number of holes dug a day may be decreased.

Cost of Digging Post and Pole Holes.*—A post hole digger may be termed a tool that does its digging by being driven into the ground, and, as it loosens the earth, picks it up so it can be taken out of the hole.

An auger is not driven into the ground like a digger, but is forced down into the ground by a man pressing on it, while at the same time he turns it as a carpenter does an auger in boring a hole through wood.

When digging a hole with a shovel and bar, it is seldom less than 12-in. wide at the top, but it loses about one-third of its diameter as it is taken down, when the holes are not over 3 ft. deep. This is due to the fact that the shovel used for this purpose cannot be worked in a smaller hole. Time is lost in hard ground by having to change from the shovel to the bar, as it is necessary to use the latter to loosen the earth.

We are enabled to give a record of digging some post holes by hand with the bar and ordinary long handled shovel. The fence posts were $7\frac{1}{2}$ ft. long, $2\frac{1}{2}$ ft. being put into the ground. The diameter of the post was 6 ins. The soil was a red clay. The holes being $2\frac{1}{2}$ ft. deep, were 12 ins. in diameter at the top, but averaged 10 ins. This made 1½ cu. ft. of excavation for each hole. The wages paid to the laborers were \$1.50 for a 10-hr. day. A man dug 40 of these holes per day, thus excavating about 3 cu. yds. of earth each day. This made a cost of 3½ cts. per post hole dug, and a cost of 75 cts. per cu. yd. of excavation. With 440 post holes to a mile of fences, posts being on 12-ft. centers, this cost per post gives a cost per mile of \$16.50.

A comparison of this with the cost of similar work done with an auger will no doubt be of interest. In *Engineering-Contracting* for Aug. 28, 1907, page 133, are given some costs of digging post holes with an auger. On that job 5-in. posts were used, and the holes were dug with a 6-in. auger, the holes being $2\frac{1}{2}$ ft. deep. Only $\frac{1}{2}$ cu. ft. of earth was thus excavated from the hole, as compared to 1½ cu. ft. One man in a 10-hr. day with wages at \$1.75, dig-

**Engineering-Contracting*, Dec. 18, 1907.

ging 24 holes, made a cost of 1.8 cts. per hole, or a cost per mile, 440 holes, of \$7.92. Thus it is seen that with a higher wage the cost was more than 50% less, which needs no comment in estimating the value of the patent digger and auger.

Another example of the cost of digging holes by hand was in making holes for some 12-in. steel channels that were to be used as the posts for a large storage bin for coal. The 12-in. channels were 24 ft. long, and 4 ft. of them were to be buried in the ground, embedded in concrete. For this reason the holes were made 2 ft. in diameter and 4 ft. deep.

The tools used in digging the holes were a digging bar, a shovel and a spoon. The holes were kept 2 ft. diameter to the bottom, the spoon allowing this to be done. From each hole $12\frac{1}{2}$ cu. ft. was excavated. One man dug 3 holes of this kind a day. The ground was a stiff clay, and all of it had to be loosened with the bar. With wages at \$1.50 per 10-hr. day the cost per hole was 50 cts. In a day a man excavated 1.23 cu. yds. of earth, which made a cost per cu. yd. of \$1.95. Some of the patented diggers are adapted to this work and would no doubt have reduced this cost.

Cost of Digging 600 Trolley Pole Holes.*—Holes for trolley poles are generally dug by hand. Under most specifications they are not paid for by the hole, but are included in the price of other line work. For this reason few records of the cost of digging these holes have been kept. Poles used in large cities are generally of iron, and embedded in concrete, while those used in the smaller towns and on suburban roads are of timber. A different size hole is needed for each kind, so the cost of the holes varies somewhat.

In this article we will give the cost of digging more than 600 holes for trolley poles on a suburban line. The overhead construction was of two kinds, span wire which needs a pole on each side of the track, and single poles with a bracket to hold the trolley wire. This divided the work into two groups, and the span wire construction was further divided into double and single track work. The class of material in which the holes were dug, as well as the size of the butt of the pole, made additional division of the work. The cost of the work will be given under five groups.

A 10-hr. day was worked and the foreman was paid \$2.00 per day and the laborers \$1.50. The work was done during the months of February to July. The gang of men worked at digging the holes, raising the poles, and other overhead work during this period of time, but the cost of each item of work was kept separate. In digging the holes, the tools that the men used were: A digging bar, see Fig. 1; a round point shovel, see Fig. 2, and a spoon, see Fig. 3. The length of the handles on these was 8 ft. The holes were spaced as follows: For span construction on tangents, the poles were 110 ft. apart. On 12° curves or less they are from 80 to 110 ft. apart, while on curves of 150 ft. radius or less they were spaced from 40 to 50 ft. apart.

**Engineering-Contracting*, March 4, 1903.

Group I.—In this lot 83 holes were dug. It was for span construction of 4,775 ft. of double track. The poles were from 12 to 15 ins. in diameter at the butt, so the holes were dug about 2 ft. in diameter. The depth of the hole was governed by the specifications, which called for all holes to be 6 ft. deep, this depth to be in the natural ground. Hence, where there was an embankment, the hole had to be as much deeper than 6 ft. as the height of the embankment was above the natural ground at the place where the pole was to be planted.

This is an instance of where conditions surrounding work may change, yet specifications are not changed to suit the new conditions. When these specifications were first drawn, all the poles on suburban lines of the company in question were not placed equi-distant from the center line of the track. In cuts they were so spaced, but, wherever embankments occurred, longer poles were used, as the poles were placed outside of the toe of the slope of the embankment. This prevented having the poles in line, which made the line of poles appear unsightly, and it also added to the length of the span wire. For these and other reasons, the arrangement of poles was changed and they were set equi-distant from the center line on the embankment as well as in the cut. Under these circumstances where the embankments had settled and were made of good material, there was no need of making the holes more than 6 ft., but, as the specifications called for a greater depth, the holes were so dug. They varied from 6 to 12 ft. deep. In this group 40 pole

holes were dug 6 ft. deep, the rest being from 9 to 12 ft., 30 holes being of the last named depth. The roadbed on this section was all embankment, made of cinders and slag from a steel plant. In digging the 30 deepest holes the cinders and slag kept running into the holes, causing about three to four times as much material to be excavated as would otherwise have been taken from the hole. It was estimated that this doubled the yardage excavated from the 32 holes.

In order to brace the poles under ground, an 8-ft. second-hand

5' /

Em

Fig. 4.

sawn tie was cut into two pieces, one 3 ft. long and the other 5 ft. long, and placed as shown in Fig. 4. The short piece was put in the bottom of the hole and the large piece at the top. This also increased the amount of material that was taken from the holes. This extra material averaged 4 cu. ft. for each hole, and the contractor was paid extra for this work. When holes were dug of a greater depth than the length of the shovel handle, a foot or more of earth was dug out of the surface of the ground at the side of the hole, and the workman stood in this depression, thus allowing him readily to reach with his shovel and spoon to the bottom of the hole.

The cost of digging the 32 holes was:

Foreman	\$ 27.90
Laborers	95.25
Total	<u>\$123.15</u>

The unit cost was as follows:

	Per cu. yd.	Per hole.
Foreman	\$0.13	\$0.34
Laborers	0.47	1.16
Total	\$0.60	\$1.50

The high cost was due to the cinders as previously explained.

The cost per lineal foot of double track for the hole digging was 2.6 cts.

Group II.—All of these holes, 88 in number, were 6 ft. deep. The poles were a little heavier than those in Group I, so the holes were $2\frac{1}{2}$ ft. in diameter. Each hole had 28 cu. ft. of earth in it, thus making 91 cu. yds. for all the holes. This was the first work done, and the men were not accustomed to handling their long handled shovels.

The cost of digging the holes was:

Foreman	\$ 23.10
Laborers	83.10
Total	\$106.10

This gave a unit cost of the following:

	Per cu. yd.	Per hole.
Foreman	\$0.26	\$0.37
Laborers	0.91	0.94
Total	\$1.16	\$1.31

As there was 4,590 lin. ft. of double track, the cost of digging holes per lineal foot was 2.3 cts.

Group III.—This was span wire construction for single track work, there being 17,160 lin. ft. of track. In all 320 pole holes were dug. The holes averaged $3\frac{1}{2}$ ft. in diameter, and were from 6 ft. to 12 ft. deep. About 20% were deeper than 6 ft., 10% being 8 or 9 ft. deep, and 10% from 10 to 12 ft. deep. From the holes 516 cu. yds. of earth were excavated, being 1.6 cu. yds. as an average from each hole. This large size hole was needed because the poles were extremely large in diameter and heavy—much larger than they were needed. This, too, was owing to the specifications, which stated the smallest size in diameter that would be accepted, but failed to state the largest dimensions that would be taken. Some of the poles furnished by the timber contractor were 3 ft. or more in diameter at the butt. This not only added to the cost of digging the holes, but also to the setting of the poles, and other details of the work. Special eye bolts had to be made for a large number of the poles, and some longer crossarms had to be obtained to carry the feed wires.

Ten of the 6-ft. holes were dug in quicksand. These gave some trouble, and additional expense. An expedient used in digging these holes was to take a barrel, and, after knocking the two heads out of it, to put it in the hole. Then all the excavation was done from within the barrel, sinking it as the hole was dug. Thus the sides of the hole were sheathed, and by means of a hand pump the water

was kept out while the digging was going on. If the quicksand occurs for a greater depth than the height of one barrel, a second barrel should be used on top of the first. This second one should be a little larger than the first, so it will go down around the lower one. The pole must be raised in such a hole as soon as it is dug.

The total cost of digging the 320 holes was as follows:

Foreman	\$ 77.80
Laborers	249.35
Total	<u>\$427.15</u>

This gave the following unit cost:

	Per cu. yd.	Per hole.
Foreman	\$0.13	\$0.24
Laborers	0.68	1.09
Total	<u>\$0.81</u>	<u>\$1.33</u>

The cost per lineal foot of single track for the hole digging was 2.5 cts.

Group IV.—This was for 2,188 lin. ft. of single track, a branch of the other line. The curves were sharper, hence the poles on the curves were closer than on the main line. The poles were all less than 20 ins. in diameter, so the holes were made 2 ft. in diameter. There were 64 poles, and only a few of the holes were deeper than 6 ft. About 19 cu. ft. were excavated from each hole, no underground braces being used. This made 45 cu. yds. excavated from the 64 holes. The cost of digging the holes was:

Foreman	\$ 9.00
Laborers	40.50
Total	<u>\$49.50</u>

The unit cost was as follows:

	Per cu. yd.	Per hole.
Foreman	\$0.29	\$0.14
Laborers	0.90	0.65
Total	<u>\$1.10</u>	<u>\$0.79</u>

The cost per lineal foot of single track for the digging was 2.2 cts.

Group V.—This was side pole construction for single track, using a bracket made of pipe, on the pole. There were 5,700 lin. ft. of this construction, the poles being spaced about 80 ft. apart. Only a few of the holes were deeper than 6 ft., but, as the poles were large, the holes were $3\frac{1}{2}$ ft. in diameter. The bracing blocks were used for these poles. An average of 36 cu. ft. was excavated from each hole, and, as there were 69 holes, 33 cu. yds. were excavated.

The cost of digging the holes was:

Foreman	\$13.00
Laborers	54.00
Total	<u>\$66.00</u>

This gives a unit cost of:

	Per cu. yd.	Per hole.
Foreman	\$0.18	\$0.18
Laborers	0.59	0.78
Total	\$0.72	\$0.96

The cost per lin. ft. of single track was 1.2 cts.

A comparison of the cost of each group is shown in the following table, also the average cost for the entire job:

	Cost per hole.	Cost per cu. yd.	—Cost per lin. ft.—	
			Double track.	Single track.
Group I	\$1.50	\$0.60	\$0.026
Group II	1.21	1.16	0.023
Group III	1.33	0.81	\$0.025
Group IV	0.79	1.10	0.023
Group V	0.96	0.72	0.012
Average	1.34	0.83	0.0245	0.0235*

*Bracket construction (Group V) left out of this average.

It will be noticed that the cost per hole varied directly with the size of the hole. Adding to the diameter and the depth increased the cost. The cost per cubic yard was high when the hole was small and low when the hole was large. The cost per lineal foot for span wire construction varied but little. Naturally the single track was about the same as double track.

Weight of Ashes, Garbage, Etc.*—In the Transactions of the American Society of Civil Engineers for April there is a valuable paper by Mr. H. de B. Parsons, entitled "Disposal of Municipal Refuse and Rubbish Incineration." From that paper we have abstracted data that may be of use to our readers.

Mr. Parsons gives the following as average weights per cubic yard:

	Lbs. per cu. yd.
Rubbish (paper, rags, old furniture, etc.)	200
Street sweepings	850
Garbage	1,150
Ashes	1,350

The weight of ashes varies from 1,200 lbs. to 1,500 lbs. per cu. yd. Ordinary household ashes contain about 15% of unburned coal; but steam-ash averages about 24% to 30% coal, the lower figure being for bituminous, and the higher figure for anthracite coal.

Mr. Parsons states that the mixed ash collections from New York City contains 30% to 35% combustible matter.

Rubbish, as ordinarily piled in carts, or without extra packing, weighs 130 lbs. to 225 lbs. per cu. yd. In Boston it averages 203 lbs. per cu. yd.; in New York it averages about 140 lbs.

The weight of street sweepings ranges from 860 lbs. to 1,400 lbs. per cu. yd., depending upon the dryness of the weather and the time of collection.

*Engineering-Contracting, July 18, 1906.

A large table is given by Mr. Parsons showing the average per capita weights of city refuse collected in different cities. From that table the following was deduced, showing the average collection of refuse per capita per day:

	Lbs. per day.
Garbage	0.53
Street sweepings	0.50
Ashes	2.23
Rubbish	0.21
Total per capita.....	3.47

Cost of Garbage Reduction and Collection at Cleveland, O.*—The city of Cleveland, O., owns and operates its own garbage collection and reduction plant. This plant had cost the city on Dec. 31, 1906, a total sum of \$181,307, divided as follows:

Reduction plant (incl. \$15,000 bldg.).....	\$146,297
Collection plant	35,010
Total	\$181,307

In acquiring the plant the city has assumed a debt of \$155,000 in bonds, the interest on which is paid by the city out of general funds. The reduction plant includes 50 acres (\$25,000).

During the year 1906 there were collected and treated by the city plant 69,872,000 lbs., or 34,891 tons of garbage. The cost of this collection and treatment is given in detail in a report presented to the Cleveland City Council by the Board of Public Service, Mr. W. J. Springborn, President. Mr. Springborn has furnished us a copy of this report for examination, and from it we have taken the statistics given above.

The figures of most value and interest, however, are those showing by items the income and the operating expenses of the plant for the last calendar year. These figures are of value particularly because they give us specific costs of collecting and of treating garbage by the reduction process with a well managed and reasonably well designed and equipped plant. Prices of supplies and wages of labor are not given and various other important data are omitted.

We give in Table I the itemized operating expenses for collecting and reducing 34,891 tons of garbage at Cleveland, O., in 1906. The totals are as they are given in the report, but the several items have been extended by us to give the unit costs as well as the totals. It may be noted also that the totals are given separately in the report for the two half-year periods, Jan. 1 to June 30 and July 1 to Dec. 31; we have not made this separation. The figures given are the actual costs of collecting and reducing the garbage; these costs may be summarized as follows:

	Per ton.
Collection	\$2.137
Reduction, per ton.....	2.385
Extraordinary expenses	0.253
Total	\$4.785

**Engineering-Contracting*, May 2, 1907.

This total, it is to be noted, does not include interest on the bonds, which at 4% would be \$6,200, or nearly 18 cts. per ton of garbage handled; nor does it include any charge for general administration expenses, a wholly indeterminate sum. Adding the interest charges brings the total cost per ton to \$4.945.

The net cost to the city of collection and reduction is of course a less amount since the reduction process preserves the grease and other salable products, which are disposed of and constitute a source

TABLE I.—ITEMIZED COST OF OPERATING GARBAGE COLLECTION AND REDUCTION PLANT AT CLEVELAND, O.

	Total	Per ton.
Labor at plant.....	\$ 43,732	\$1.254
Coal at plant.....	19,980	0.572
Superintendence and clerk.....	3,363	0.096
Repairs and renewals.....	4,763	0.136
Press cloths	2,565	0.073
Insurance	283	0.008
Office supplies	146	0.004
Oil, waste, light, water, etc.....	5,113	0.146
Press racks	806	0.023
Taxes	346	0.009
Commission, analysis, etc.....	326	0.009
Freight, purchase dead animals.....	1,455	0.041
Total reduction expenses.....	\$ 82,363	\$2.285
Labor, teamster, etc.....	43,829	1.256
Feed	10,991	0.315
Freight on garbage.....	5,285	0.151
Superintendence and clerk.....	2,870	0.082
Shoeing, etc.	2,431	0.069
Harness repairs and renewals.....	1,204	0.034
Painting garbage cars.....	919	0.026
Repair cars and wagons.....	4,280	0.122
Rent and taxes.....	473	0.014
Insurance	450	0.012
Oil, light, telephone, etc.....	1,601	0.045
Total collection expenses.....	\$ 74,334	\$2.127
Auditing	150	0.004
Loss of horses.....	1,473	0.042
Depreciation reduction plant, at 10%....	3,382	0.097
Depreciation collection plant, at 10%....	3,351	0.095
Depreciation new reduction equipment..	526	0.015
Total extraordinary expenses.....	\$ 8,892	\$0.253
Grand total operating expenses....	\$166,609	\$4.765

of income which is credited against operating expenses. There are also at Cleveland minor sources of income. The report mentioned above summarizes the income account as follows:

Product sold	\$ 98,351
Inventory of product.....	8,694
Sale of raw material.....	254
Rents	127
Miscellaneous revenue	1,455
Total income.....	\$106,991

We have then the following net cost to the city of treating one ton of garbage:

Total cost of disposal, per ton.....	\$4.945
Total income from operation, per ton.....	3.07
Net cost of disposal, per ton.....	\$1.875

It will be seen by referring to Table I that the total cost of reduction proper was \$2.385 per ton, not including depreciation and interest on cost. Adding these two items we get a cost of about \$2.62 per ton, so that the income for operation gives a profit on reduction alone of 45 cts. per ton. These figures are significant, not as specific guides as to the cost and profit of reduction, but as indicating that the reduction process of garbage disposal may be made self-supporting.

The income from operation comes chiefly from the sale of product. The nature and amount of this product are indicated by Table II, rearranged from figures given in the report. In addition to the character and quantities of materials produced for sale the table shows the prices fetched by these materials in the market. It is interesting to note that the amount of grease per ton of garbage treated was 61.05 lbs., or 3.06%.

In considering the figures given it is important to remember that they are a record of an individual case. They are interesting as being almost the first and certainly the most complete published figures of the cost of garbage disposal by reduction, and for this reason they have been given.

TABLE II.—SHOWING CHARACTER AND VALUE OF SALABLE PRODUCT FROM CLEVELAND, O., GARBAGE REDUCTION PLANT.

Article.	
Grease, 2,140,800 lbs.....	\$41,940
Dry tankage, 6,282,500 lbs.....	13,724
Pressed tankage, 2,315,400 lbs.....	2,564
Hair	87
Tails	45
Hides	1,493
Total	\$59,853

Cost of Garbage Disposal, Milwaukee.—Mr. Rudolph Hering is authority for the following data. The weight of garbage is:

	Per cu. yd.,
Ashes and rubbish mixed.....	1,040
Dry manure	370
Clear ashes	1,210
Rubbish alone	850

A horse produces 22 lbs. of manure daily.

In 1906 the city had a population of 250,000. The garbage collected was 48,400 loads, or 28,500 tons, of which 25,200 tons were burned in a furnace. It required 160 lbs. of coal to burn a ton of garbage, coal costing \$3.80 per ton, which is equivalent to 19 cts.

per ton of garbage. There are 8 tons of residual ash from each 150 tons of garbage.

The cost per ton in 1906 was:

	Per ton.
Collection	\$1.66
Operating hoist	0.10
Operating furnace	1.24
Burial	0.01
Total	\$3.01

The cost of the crematory plant was approximately as follows:

Buildings	\$16,795
Steel trestles	2,510
Hoists	2,900
Engines and dynamos	4,113
Pump	494
Chimney (150 ft. high)	6,399
Three furnaces	27,750
Patent rights	12,500
Total	\$74,461

Garbage Incineration, San Francisco.—The garbage is cremated by a private company for 20 cts. per cu. yd., garbage being delivered by the city at the plant. The plant was built in 1897 at a cost of \$75,000, and handles 650 cu. yds., or about 260 tons per day, which is less than half its capacity as no force works nights.

The following gang works 11 hrs. (in 1900):

1 foreman	\$ 2.50
1 office man	2.50
1 night man	2.50
5 firemen, at \$1.75	8.75
5 firemen-helpers, at \$1.50	7.50
10 men on garbage floor, at \$1.625	16.25
Total	\$40.00

This labor is equivalent to 6 cts. per cu. yd., or 15 cts. per ton, but does not include the disposal of the ash and clinker. There were 169,200 cu. yds. of garbage burned in 1899.

Cost of Removing Ashes.—The average cost of removing ashes, exclusive of dump maintenance, at Rochester, N. Y., in 1906, was \$0.353 per cu. yd. The average weight of a cubic yard of ashes was 921 lbs. The average cost of maintenance of dumps, ashes, scrapings and sweepings was \$0.1073 per team load. A team load weighed 3,682 lbs., the average weight of the wagon being 2,100 lbs.

Cost of Tile Drains.—Clay tiles for drainage purposes are usually round in section, and are usually made in 1-ft. lengths. In soil that can be spaded, a special ditching spade should be used. The blade of this type of spade is narrow and very long (18 ins.), and strongly curved forward to give greater stiffness. With such a spade, a trench 5 ft. deep, and not more than 15 ins. wide at the top, can be dug. Trenches 5 ft. deep are 10 to 12 ins. wide on top, and are taken out in two spadings, or benches. The bottoms of the trenches are shaped so as to fit the tile, by using a tile hoe or scoop

of proper shape, different widths being used for different sizes of tile. The tiles are laid by a man standing on the surface of the ground, using a tile hook for the purpose of placing the tiles in the trench. The trench is backfilled by a team dragging a plow provided with a long evener, so that there is one horse on each side of the trench.

Mr. C. G. Elliott gives the following as the actual cost of draining an 80-acre farm in Illinois:

Tile.			Cost per lin. ft.			Total.
Size, ins.	Lin. ft.	Depth, ft.	Tile, cts.	Laying, cts.	Total, cts.	
3.....	7,030	3	1.32	2.00	3.32	\$233.40
4.....	8,280	3½	2.00	2.00	4.00	331.20
5.....	850	4	3.00	2.42	5.42	46.07
6.....	2,700	5	4.00	3.66	7.66	206.82
7.....	1,000	6	5.00	3.72	8.72	97.20
Total, 80 acres, at \$11.43 per acre.....						\$914.69

The cost of "laying," as above given, includes the cost of digging the trench, laying the pipe and backfilling. The men were paid \$2 a day, being skilled diggers and tile layers. The soil was a black loam 2½ ft. thick, under which was a yellow clay subsoil.

For tile up to 6 ins. diameter, Elliott estimates 1½ cts. per lin. ft. for labor of trenching 3 ft. deep and laying the tile; and he allows 0.3 ct. per lin. ft. for backfilling.

The manufacturers of tile do not have uniform list prices from which discounts are given. The following net prices are quoted (1905) for New York delivery in carload lots:

Size of drain tile, ins.	Weight, lbs. per ft.	Net price per ft., cts.
2.....	3	1.45
2½.....	4	1.72
3.....	5	2.18
4.....	7	3.04
5.....	9	3.98
6.....	12	5.38
8.....	19	8.20
10.....	28	14.50
12.....	40	18.80

Tile drains are frequently used for road drainage. In such cases the trench is usually filled part way up with broken stone or gravel, the cost of which must be included in the bidding price per lin. ft. of drain. Tile collars to be used at joints are occasionally specified, but they are of questionable value, and are rarely used in land drainage. On roadwork done by the author, the cost of laying 4-in. tile in a trench was ¼ ct. per lin. ft., exclusive of digging the trench and filling with gravel. The man laying tile received 16 cts. per hr., and he averaged 640 ft. laid per 10-hr. day.

In New Jersey roadwork, where tile drains are used, the 4-in. tiles are frequently specified to be laid on a 1-in. yellow pine plank, 6 ins. wide, in a trench 3 ft. deep. If plank costs \$20 per M delivered this item adds 1 ct. per lin. ft. The average bidding price in New

Jersey has been about 12 cts. per lin. ft. for a 4-in. tile drain complete.

Weight of Drain Tile.—Porous or farm tile laid 2 or 4 ft. deep on one or both sides of the roadway is the best method of securing underdrainage for highways. Tile may be had from 2 to 30 in. in diameter. The smaller sizes are usually 1 ft. long and the larger sizes are 2 or 2½ ft. long. The accompanying table shows the weight per foot and the average carload for various sizes of tile:

	Weight per ft., lbs.	Av. carload. No. pieces.
4-in. tile.....	6	6,500
6-in. tile.....	8	5,000
6-in. tile.....	11	4,000
7-in. tile.....	14	3,000
8-in. tile.....	18	1,300
10-in. tile.....	25	800
12-in. tile.....	33	600
14-in. tile.....	43	400
16-in. tile.....	50	300
16-in. tile.....	53	250
18-in. tile.....	70	200
20-in. tile.....	83	160
22-in. tile.....	100	160
24-in. tile.....	113	150
30-in. tile.....	191	65

Prices of Tile Drains in Place.*—Table III was compiled by Mr. George M. Thomson, County Surveyor of Green County, Iowa, to facilitate the making of estimates on county ditches. Mr. Thomson writes us that the table agrees very closely with bids received during the last two years for doing such work in Greene County. The prices given in the table are for excavating the trench, laying the tile and refilling the trench. The prices given are per foot deep and rod long. For instance, suppose the drain is to be 7.15 ft. deep and is to be laid with 12-in. tile. In the column under 7 ft. and opposite 12 in. will be found 40 cts., the price per foot deep; then $7.15 \times 40 = \$2.86$, the price per rod for 12-in. tile laid 7.15 ft. deep.

Cost of Digging a Trench and Laying Tile Drain.†—In laying some tiles for the drainage of a wagon road a trench 2 ft. wide on the top and 1 ft. on the bottom, with an average depth of 3 ft., was excavated. The tiles used were 4-in. and 8-in. They were laid in the trench and broken stone placed around them, and over them, before backfilling the trench. This allows the water to enter the tiles much easier than when dirt is put around them. In all, 7,500 lin. ft. of trench was dug.

There were excavated 1,250 cu. yds. from the trench, 75 cu. yds. being rock. The rock was all in the bottom of the trench, sometimes running across the bottom, while in some places it was only found on one side of the trench. Some of it was loosened with bars and picks, but the most of the rock had to be blasted. The rock excavated was broken up by hand into about 2-in. ring stone, and

**Engineering-Contracting*, Jan. 22, 1903.

†*Engineering-Contracting*, Sept. 16, 1903.

TABLE III.—EXCAVATION TABLE FOR MAKING ESTIMATES ON DITCH WORK.

Size of Trench and 6-in.	Average Depth in Feet.									
	5 ft.	6 ft.	7 ft.	8 ft.	9 ft.	10 ft.	11 ft.	12 ft.	13 ft.	14 ft.
5-in.	.15	.18	.20	.25	.30	.35	.40	.45	.50	.55
6-in.	.18	.20	.25	.30	.35	.40	.45	.50	.55	.60

was used around the tiles, very little stone being purchased for this purpose.

The wages paid on the job for a 9-hr. day were \$3.50 for foremen, \$1.35 and \$1.40 for laborers, and 75 cts. for water boys. One foreman and one gang of 16 men worked for 9 days, and the job was completed by 2 foremen and 26 men, working 10 additional days.

The total labor cost for excavating the trench, breaking up the stone, laying the tile, and placing broken stone around it, and backfilling the trench was \$674.15, or 52 cts. per cu. yd. of trench.

The tile laying was done by one man and an assistant, who wheeled the tiles and laid them alongside of the trench, the tile layer then placing them. These two men, in a half day, could lay tiles in the trench that the entire gang had dug during a day. After they had laid the tiles, with the assistance of a few additional men, they did the backfilling of the trench. The labor cost of placing the tiles was \$26.14, making a cost of 0.35 ct. per lin. ft. The cost per lin. ft. for excavating, breaking rock and backfilling was 16 cts., making a total cost per lin. ft. of the completed drain of about 9 cts.

Cost of Farm Drainage.—Several excellent articles on the methods and cost of farm drainage appeared in *Engineering-Contracting*, Dec. 4, 1907, Oct. 21, Nov. 4 and Nov. 18, 1908, Oct. 13 and Oct. 24, 1909. These articles occupied about 25 pages, of which the following is a very brief summary.

Mr. L. G. Hicks states that, in draining a farm near Omaha, the cost of tile drainage was \$23 per acre. Wages were \$1.50 per 10-hr. day and board, the board amounting to \$0.50, making a total of \$2 per day. Material was black loam, which cost 21 cts. per cu. yd. to excavate from ditches 3½ ft. deep and 12 to 15 ins. wide. The ditch was shaped up with a tile spoon, at a cost of 2½ cts. per lin. ft., which is equivalent to adding another 20 cts. per cu. yd. The backfilling was done by two men and two horses with a plow at a cost of 1 ct. per cu. yd. Hence the total cost was 43 cts. per cu. yd. The cost of laying the tile was as follows:

	Per 100 ft. cts.
3 or 4-in. tile.....	5
6-in. tile.....	6.7
8-in. tile.....	10

With a tile hook a man lays 100 ft. of 3-in. tile in 15 mins., or at the rate of 4,000 ft. per day.

The cost of this work on a 76-acre farm where 25,150 lin. ft. of tile were laid was:

	Per acre.	Per lin. ft., cts.
Surveys	\$ 1.45	0.43
Labor	12.83	3.32
Material	8.55	2.55
Total	\$22.83	6.30

A 476-acre "experimental farm" in Minnesota was drained, using 4, 6 and 8-in. tile. Farm laborers received \$2 a day, and team with

driver was rated at \$4.50 per day. The cost of loading, unloading and hauling was 80 cts. per ton for the first mile, plus 20 cts. per ton for each additional mile, load averaging $3\frac{1}{4}$ tons over ordinary fields. The contract price for trenching (by hand), tile laying and backfilling was \$2.42 per 100 lin. ft. of trench 3 ft. deep, plus 4 cts. for each additional foot of depth. The average trench work done by one man, at \$2 per day, was:

	Lin. ft.
3-ft. trench	100
3.5-ft. trench	96
5-ft. trench	80

After a man had acquired some experience, 4 to 6-in. tile were laid with a tile hook at the rate of 2,000 ft. in 10 hrs., where the trench was in good condition and the tile convenient.

After the tile were laid they were covered with earth 4 to 6 ins. deep, called "blinding." A man astride of the trench cuts off earth from each side with a tile spade. This blinding is done at the rate of 4,000 ft. in 10 hrs. The blinding holds the tile in place.

The backfilling was done in three ways: (1) By hand; (2) by drag scraper; (3) by plow and road machine. The costs were as follows:

A trench 3 ft. deep was backfilled by hand at a cost of \$0.56 per 100 lin. ft., wages being \$2.00 per 10-hr. day.

A trench $3\frac{1}{2}$ ft. deep was backfilled by a drag scraper, two horses and two men, for \$0.60 per 100 lin. ft. of trench.

A similar trench was backfilled for \$0.32 per 100 lin. ft., using a plow first and a road machine afterward. Two teams and drivers were used on the plow, one team on each side of the trench. A long evener was used, and the plow shifted as desired. After two round trips, the same gang completed the filling by means of a road machine.

In Illinois the average depth to lay tile is about 3 ft., and the distance apart of lateral drains is about as follows:

	Ft. apart.
Light, sandy soil.....	150 to 300
Heavy loam	75 to 150
Gumbo	30 to 100

The cost in dollars per acre for tile drains may be roughly estimated by dividing 1,500 by the distance apart (in feet) of the lateral drains. Thus, if the drains are 150 ft. apart, the cost per acre is $1,500 \div 150 = \$10$.

In Utah, 40 acres of irrigated farm land were drained, using 4, 5 and 6-in. tile, laid 4 to 5 ft. deep. The cost was \$13.50 per acre. There were 5,300 lin. ft. of tile used, at the following average cost:

	Per 100 lin. ft.
Tile	\$ 6.40
Labour	3.80
Total	\$10.20

Mr. Jas. T. Taylor gives the following relative to pipes laid in 1891 for irrigating 4,200 acres in the Alessandro District, California.

The pipes were vitrified sewer pipes and cement pipes, 8 to 12 in. diam., and these pipe lines, including trenching, etc., cost \$76,300 for 40 miles of pipe, or \$18.15 per acre for the lateral system. This is equivalent to 50 ft. of lateral pipe per acre, at an average cost of 86 cts. per ft. laid.

Cost of Tile Trenching With a Machine.*—A machine made by the Buckeye Traction Ditcher Co., of Findlay, Ohio, was used on the Northwest Experiment Farm, University of Minnesota, in 1903. The machine dug a trench 14½ in. wide and 4½ ft. deep. It had an 8-hp. boiler and consumed 450 lbs. of coal and 4 bbls. of water per day. It dug 34,000 lin. ft. of trench in 45 days actual working time, or 744 lin. ft. per day. The men who handled the machine were inexperienced.

The following was the cost:

	Per 100 ft.
Labor running machine.....	\$0.45
Coal at \$7.50 per ton.....	0.19
Water	0.12
Oil	0.01
Repairs	0.13
Total ditching	\$0.91
Laying tile	0.18
Blinding	0.05
Incidentals	0.09
Total	\$1.23

The price of the machine was \$1,400.

Although the machine was not well handled and had not at that time (1903) been perfected, it made a very creditable record of cost, as contrasted with hand work, for the latter cost \$2.88 per 100 lin. ft. on the same farm.

Two men operated the machine.

I recently saw a machine of the same make and size on a farm in New Jersey where it was averaging 2,000 lin. ft. of trench (15 in. x 3 ft.) in 10 hrs.

Cost of Laying Small Gas Mains on Six Jobs.†—Mr. W. H. Matlack is author of the following:

In this article the cost is given of laying 4-in., 6-in. and 10-in. gas mains on 6 different jobs, there being a total of 19,924 lin. ft. of pipe laid. The 10-in. main was first laid, the 6-in. and 4-in. following. The work was done in the months of May and June, 1902. The weather during that spring was unusually wet and all costs are a little higher than they should be, yet the tables will give a fair idea of what work will cost under such conditions.

The ditch averaged 3 ft. 6 in. in depth and was 28 in. wide. The soil was half and half sandy clay and gumbo, with the exception of about 150 ft. of quicksand encountered in laying the 10-in. line. The 10-in. line was almost all laid on rainy days in a wet

**Engineering-Contracting*, Nov. 4, 1903.

†*Engineering-Contracting*, March 21, 1903.

ditch. From 1,500 to 2,000 ft. of the ditch were one-third full of water at one time, which caused it to cave, and about 900 ft. had to be redug, aside from bailing the water with buckets from some 2,000 ft. of it.

A creek was crossed with the 10-in. line. Here lead joints were used, but all other joints on the six jobs were made with cement. The following fittings were put in on the 10-in. line: Three 10-in. drips, thirteen 5-in. tees, one 10-in. cross, and one 10 x 16-in. reducer.

The 6-in. line No. 1 was laid next and under similar conditions, and the following fittings used: Three 6-in. crosses and three 6 x 4-in. tees.

The 4-in. lines were put in when the weather was good and the soil dry. Records kept in laying the 4-in. pipe showed that 3 ft. of yarn would make four joints and that one sack of cement would caulk and cap 22 joints. Lehigh Portland cement was used, and tests previously made showed tensile strengths of from 500 to 600 lbs. per sq. in.

The gang averaged 25 men. The best day's work consisted of 52 lengths of 6-in. pipe and 29 lengths of 4-in. pipe, the ditch being opened, pipe laid and caulked in 10 hours. In backfilling the trench the earth was hand tamped in from 6 to 8-in. layers. The team was used in handling pipe and other supplies from the plant to the job, an average distance of two miles.

The following wages were paid: Foreman, 27½ cts. per hour; caulkers, 22 to 25 cts. per hour; laborers, 17 cts.; team and driver, 45 cts.; watchman, 17½ cts., and water boy, 15 cts. per hour. A night watchman was employed throughout the job and a man for Sundays.

The cost of the work, divided into various items of labor for each lineal foot, is as follows:

Job No.	"A"	"1"	"2"
Size	4-in.	6-in.	10-in.
Total ft. laid	1,412	1,302	5,781
Team and driver	\$0.007	\$0.014	\$0.022
Foreman	0.007	0.006	0.007
Superintendence	0.005	0.007
Excavation	0.040	0.022	0.058
Caulking	0.004	0.007	0.012
Backfilling	0.040	0.022	0.058
Sundry expenses	0.002	0.006
Total cost per ft.	\$0.222	\$0.226	\$0.171
Job No.	"B"	"C"	"D"
Size	4-in.	6-in.	6-in.
Total ft. laid	595	841	982
Team and driver	\$0.009	\$0.011	\$0.120
Foreman	0.009	0.003	0.150
Superintendence	0.005
Excavation	0.052	0.409	0.500
Caulking	0.007	0.009	0.110
Backfilling	0.050	0.125	0.187
Total cost per ft.	\$0.127	\$0.125	\$0.127

The sundry expense item is for the watchman and water boy.

All the pipe was tested before going into the ditch and all leaky joints were cut out and redriven. There were 18 such joints on the 10-in. line due to rain over night on green joints. After the pipes were all laid they were all tested. The 10-in. line was tested from four parts. The others were tested once. This testing, which was all in the air, was done with an old style hand pump that required 10 men to operate. In testing, 12 men were used, 10 to pump up the line, 1 to snap joints and 1 to look after the gage. The time consumed by a test varied from 45 mins. to 1½ hrs. This time is distributed as well as possible between the laborers and caulkers, as all took a hand.

After completing the work a final test was made, as shown by Fig. 5. The piping was placed and a meter set; the pressure was then equalized by running gas from an old 10-in. line through the 1-in. line and into the new line, this line being opened at B for 15 mins. At the end of this time B was closed and A opened, allowing the gas to pass through the meter and to register. After

Fig. 5.

the register was made, which took almost 10 mins., the meter was read and noted, then left standing for 2½ hrs. At the end of that time it was reread and finding the reading to be the same as at the time of the first registering, it was known that no gas had passed through the meter, hence there were no leaks in the new line. The following day men were sent along the line and all drip leads were opened, allowing all air to pass out.

Cost of Laying Wrought Iron, Screw-Joint Pipe for Compressed Air Main.—Mr. E. E. Harper gives the following:

The work consisted of laying 7,000 ft. of 8-in. and 4,000 ft. of 6-in. wrought-iron, screw-joint pipe for a compressed air line carrying 80 to 90 lbs. pressure. The work was all performed by common labor, none of the men being experienced in pipe laying.

The greatest cause of delay in laying screwed pipe is the difficulty in getting each successive length of pipe into line and keeping it there until the first threads take hold and the pipe begins to screw together. To overcome this difficulty a cradle for supporting the pipe at the joint, a jack for adjusting and supporting the outer end of the pipe and a straight-edge for lining the pipe were devised. The cradle holds the threaded end of the pipe in position to enter the

sleeve coupling on the last joint laid; the jack allows both vertical and horizontal adjustment of the joint of pipe; and the straight-edge shows when the pipe is in line ready to screw together. The cradle was simply a wood block, 8 x 8 ins. x 24 ins. in length, with a groove having a 4-in. radius cut in its top. The jack is shown by Fig. 6 and the straight-edge by Fig. 7. The movable block on the straight-edge is necessary because it is almost impossible to make a 12-ft. straight-edge that will remain true for more than a day.

Fig. 6.—Jack.

These devices saved fully 50% over the crude and unsatisfactory method of using blocks to hold the pipe in line. There was no straining and lifting to hold the pipe in place, and as the pipes were started together straight there were no stripped threads and bad joints, and the pipe made up so easily that one man with a pair of 3-ft. tongs often screwed an 8-in. pipe half way up; it was then completed by four men using two pairs of tongs with 8-ft. handles.

Fig. 7.—Straight Edge.

The threads, both male and female, were cleaned with wire brushes. Dixon's pipe joint compound was used on all screwed joints. Ring gaskets of 1/16-in. Rainbow packing were used on flange joints, the gasket being pasted to one flange with coal-tar roofing paint, which held it in position while the joint was being made.

Six-Inch Pipe Line.—The total length of 6-in. pipe was 4,118 ft. The pipe was 6-in. lap welded casing weighing 15 lbs. per lin. ft.

It was laid with sleeve couplings, $11\frac{1}{2}$ threads per inch, with a flange union every 150 ft. and U-bends for expansion every 500 ft. The average length of joints was 20.1 ft.; an average of 582.2 ft. of pipe or of 29.2 joints, was laid per 10-hr. day. The best day's work was 1,055 ft., or 53 joints, with 6 men working 9 hrs., making 177.5 ft. per man; the poorest day's work was 120 ft., or 6 joints, by 6 men working $3\frac{1}{2}$ hrs. The work was done from Aug. 15 to 24, 1907, in fair weather except, for one day, when the men worked 4 hrs. in rain and laid 22 joints. The men walked $2\frac{1}{2}$ to 3 miles to and from work. The average gang was: 4.85 men at 20 cts. per hour, 1 foreman at 30 cts. per hour, and 1 waterboy at 10 cts. per hour. The cost of pipelaying was as follows per 100 ft.:

	Per 100 ft.
Clearing right of way.....	\$0.827
Hauling and distributing.....	1.578
Blocking to grade.....	0.116
Constructing bents.....	0.450
Anchors for U-bends.....	2.290
Painting	0.900
Tools	0.100
Testing	0.300
Laying	3.127
Surveying and superintendence.....	0.700
Total	\$9.898

The total cost per foot exclusive of cost of pipe was 9.898 cts., or, say, 10 cts. The following notes explain the work included in the various items:

Clearing.—Removing small brush for a width of 10 ft.

Hauling.—The average hauls were 2,000 ft. over bad roads, steep and rough. This item includes loading pipe on cars and unloading, hauling and distributing, including seven U-bends. Teams and drivers got \$3 per day.

Blocking.—Includes temporary blocking and bending pipe in five places by building fires on it.

Anchors for U-Bends.—Includes 8 piers at \$12 each, including bolts and clamps.

Bent Construction.—Includes carpenter work only on about 20 bents, averaging 3 ft. in height and made 4 x 6-in. stuff.

Painting.—Includes cost of painting and cleaning pipe with wire brushes with paint costing \$1 per gallon and labor at 20 cts. per hour. The pipe was painted one coat.

Tools.—Includes shopwork and depreciation.

Eight-Inch Pipe Line.—The total length of 8-in. pipe was 7,101 ft. The pipe was 8-in. O. D., lap-welded casing weighing 20 lbs. per foot, laid with sleeve couplings, $11\frac{1}{2}$ threads per inch. The average length of joints was 19.15 ft. There was a flange union every 150 ft., and U-bends for expansion every 500 ft. An average of 591.6 ft. was laid per day, of 10 hrs., or 26.3 joints. The best day's work was 613 ft., or 22 joints, by 6 men, including foreman; the poorest day's work was 280 ft., or 20 joints, by 7 men, including foreman. The work was done from July 2 to Aug. 5, 1907, the weather being

hot and sultry, the thermometer ranging from 85° to 100°, and averaging 90° in shade. The average gang was: 5.92 men at 20 cts. per hour, 1 foreman at 30 cts. per hour, and 1 waterboy at 10 cts. per hour. The cost was as follows per 100 ft.:

	Per 100 ft.
Surveying and superintendence.....	\$ 1.000
Laying	3.580
Clearing	0.187
Hauling and distributing.....	1.032
Blocking to grade.....	1.110
Constructing bents	1.069
Anchor for U-bends.....	2.525
Painting	1.200
Tools	0.102
Testing	0.388
Total cost of laying.....	\$12.202
Cost of pipe.....	76.400
Grand total cost.....	\$88.602

The total cost per foot, exclusive cost of pipe, was thus 12.2 cts., and including cost of pipe 88.6 cts. The following notes explain the work included in the various items:

Clearing.—Removing small brush for a width of 10 ft.

Hauling.—Includes 12 U-bends, which cost \$1 each to haul; teams and drivers, 30 cts. per hour; laborers, 20 cts. per hour, and foreman, 30 cts. per hour.

Bent Construction.—Includes carpenter work only on about 80 bents of 4 x 6-in. stuff, spaced 30 ft. apart and ranging in height from 1 ft. to 14 ft., averaging 6 ft. high.

Anchor for U-Bends.—Includes 12 piers at \$15 each, including bolts and clamps.

Painting.—Same as for 6-in. pipe.

Testing.—Includes laying and connecting 200 ft. of 4-in. pipe to pump line. Tested to 110 lbs. hydraulic pressure. Leaks developed in two tees in line and these were repaired, line tested again and found tight. The pipe cost \$76 per ton (100 ft.) f. o. b. McKeesport, and the freight to Flat River was 40 cts. per ton.

Cost of Maintaining Teams.—I have maintained teams at the following cost per month per team of two horses:

1/4 ton of hay, at \$10.....	\$ 5.00
30 bu. oats, at \$5 cts.....	10.50
Straw for bedding.....	1.00
Shoeing and medicine.....	2.00
Total	\$18.50

A generation ago there were 2,000 horses used on the Brooklyn street railways. The cost of feeding each horse was \$10 a month, and the depreciation in value of each horse was 25% per annum.

Contract work is not so severe as street car work; still the annual depreciation is probably not less than 15%. A team, wagon and harness costing \$300 should be charged with about \$60 per annum for interest and depreciation. When the team is working it must be fed oats, when not working it can be fed on hay at half the usual cost.

The following gives the average feed of horses and mules used by the H. C. Frick Coke Co., extending over a period of 6 years: 600 lbs. of hay, 7 bu. of oats, $4\frac{2}{5}$ bu. of corn on the ear per head per month. The daily feed of each animal was two feeds of corn, 13 ears to the feed (70 lbs. per bu.), one 6-qt. feed of oats, and about $16\frac{1}{2}$ lbs. of hay. Each animal averaged about 13 miles traveled per day underground, 16 miles being the maximum 10-hr. day's work.

It is not ordinarily possible to get more than 180 days of work per annum out of a contractor's team in the North, and very frequently much less. We may, therefore, say that \$1.50 for each day actually worked by the team will cover its feed, interest and depreciation, for the year. If the driver is paid only while at work, then his \$1.50 added to that of the team makes \$3 a day for each day worked.

The cost of feeding 25 horses at work building roads near San Francisco, for a period of 12 mos., was as follows, per horse per day:

28 lbs. wheat hay, at \$15.50 per ton.....	\$0.215
12 lbs. rolled barley, at \$24.10 per ton.....	0.150
$1\frac{1}{4}$ lbs. oats, at \$27.40 per ton.....	0.020
$\frac{1}{4}$ lb. bran, at \$21.20 per ton.....	0.003
$1\frac{1}{4}$ lbs. straw bedding, at \$13.80 per ton.....	0.009
Wages, 1 stableman (\$775 for year), and hauling forage (\$281 for year).....	0.113
Total per horse per day.....	\$0.510

The above shows a consumption of nearly 42 lbs. of feed per horse per day, which seems large, but is not excessive for heavy draft horses working daily. A conservative estimate of the food waste is 5%.

A four-horse team averaged $16\frac{1}{2}$ miles traveled per day over fair macadam roads with some 5% grades. The load was 3 short tons, plus the 0.65-ton wagon; and the haul, one way, was $\frac{1}{2}$ to 1 mile.

Cost of Horse Maintenance.*—In a report to the Street Cleaning Department of Boston, Mass., Mr. Richard T. Fox, Sanitary Expert, Chicago, Ill., gives some figures as to the stable and yard expenses of that department for 1906. The following matter has been taken from that report. The street cleaning department owns 128 horses, which are used for driving purposes for machine sweeping and the removal of street dirt. Of these horses 95 are maintained directly by the department and 33 are boarded by the Sanitary Department. The net cost in 1906 for rent, repairs, shoeing, veterinary services, medicines and feed for the 128 horses amounted to \$66,283. The cost per horse per year is therefore \$517.83 or \$43.15 per month. As a comparison Mr. Fox found that the E. S. Pierce & Co., wholesale grocers of Boston, paid \$27.65 per horse per month for maintenance, the cost including shoeing, veterinary service and boarding in a public stable. Mr. Fox considers that \$19 per month is a fair average yearly price per horse, if maintained at private

**Engineering-Contracting*, Nov. 13, 1907.

expense. The horse shoeing bill for the Street Cleaning Department amounted to \$33.43 per year per horse or \$2.78 per month. The veterinary services and medicine amounted to \$17.97 per horse per year. In comparison with this Mr. Fox found that S. S. Pierce & Co. pay a little less than \$12 per year for veterinary service and medicine; the Boston Fire Department pays \$12 per year per horse, and the Knickerbocker Ice Co., Chicago, Ill., pays \$5 per year per horse.

Cost of Maintaining Horses, New York City.*—A report made by the Parsons-Herring-Whinery Commission on the cost of municipal street cleaning contains data on horse maintenance, of which the following is a brief summary. The cost of maintaining each of 1,174 horses for one year (1906) in Manhattan and The Bronx was:

Stable rental.....	\$ 41.44
Labor at stables (hostlers at \$720 yr.).....	237.00
Feed and bedding.....	171.00
Shoeing	18.36
Veterinary	5.63

Total, at \$1.20 per day (365 days).....\$473.43

The commission states that private corporations in New York City pay about \$330 per year per horse for the same maintenance that costs the city \$473.

Feed for Street Car Horses.—The daily mileage of street car horses, working in teams, is 15 miles traveled in 3 hrs. In cool weather this mileage may be covered in one trip, but in summer the time should be divided. For this sort of work a horse weighing about 1,100 lbs. is best.

A weekly report of feed should show.

	Used during week.	On hand.
Hay
Straw
Corn
Oats
Bran
Salt
Proportion of feeding.....
Average number of horses.....
Pounds of hay and meal per horse.....
Remarks
Required during week.....

In Brooklyn the old horse car companies prescribed the following feed per horse:

In summer, 15 lbs. of mixed grain ground (5 lbs. corn, 10 lbs. oats). In winter, 10 lbs. corn and 5 lbs. oats. About 15 lbs. of cut hay moistened and mixed with the meal. About 4 lbs. of cattle salt to each 100 horses. Hours for feeding, 5:30 and 10 a. m. and 4 p. m. Quantities at each feed, 10.8 and 12 lbs. respectively. Road mileage, 16 miles per day; rest Sunday. Average working life (based on 20 years experience) 7 years.

**Engineering-Contracting*, May 20, 1908.

In Providence, R. I., about 35 lbs. of straw for bedding required per horse per month. Horses in groups of 14 under the care of one stable man, who also harnesses them.

Cost of Maintaining Farm Horses and of Raising Hay and Oats in Minnesota.*—The following data should be of value both to the highway engineer, for estimating the cost of hauling, and to the contractor who may wish to raise feed for his horses. The data have been abstracted from bulletins Nos. 48 and 73 of the U. S. Department of Agriculture, entitled "The Cost of Producing Minnesota Farm Products." The bulletins contain very complete summaries of the results of careful investigations during the years 1902 and 1907 inclusive, covering about 70 farms in five counties of Minnesota. These bulletins mark the beginning of the scientific application of cost analysis to farming, and, so far as we know, are the only records of their kind in print.

The first step in ascertaining the cost of producing crops is to determine the cost of a horse hour and of a man hour. To do this the "route statisticians" (assisted by the farmers) kept accurate records of the number of hours that each horse was actually worked each day, as well as the number of hours worked by each man.

For the purpose of condensing the results, while at the same time giving the data in considerable detail, we have selected the records of Rice county, where 34 farms of about 170 acres each were recorded. There were 5.4 work horses (not including colts or driving horses) per farm. The time of the farm owner was counted as being of no more value than of his hired men. The following is the average number of hours worked per day during the years 1902 to 1907, including the time of the farm owner:

	Week Days.		Sunday.
	Man.	Horse.	Man.
January	6.80	1.16	4.85
February	6.62	1.14	4.80
March	7.57	1.34	4.63
April	9.33	4.54	4.02
May	9.02	4.00	3.46
June	9.84	3.11	3.11
July	9.22	3.44	2.82
August	10.25	4.78	2.66
September	11.02	4.07	2.93
October	9.66	3.26	2.84
November	9.08	3.05	3.55
December	7.29	1.55	4.67
Average	8.94	3.03	3.64

On 20 farms in Lyon county (averaging 250 acres each) there were 6.8 work horses per farm; and on 18 farms in Norman county (averaging 210 acres each) there were 7 work horses per farm; and the average number of hours worked was as follows:

	Lyon.	Norman.
Per week day per man.....	3.66	3.19
Per week day per horse.....	3.39	3.14
Per Sunday per man.....	3.05	3.76

**Engineering-Contracting*, June 2, 1909.

It would appear that the Sunday work consisted mainly in caring for the stock and milking the cows. There were about 12 milch cows per farm.

If the 3.64 hours of Sunday work represents the average daily time spent caring for the stock, etc., it would seem that this accounts in large measure for the small number of hours worked daily by each horse. Nevertheless, there is a surprising loss of horse time. According to the bulletin, this is in part due to the practice on many farms of having from "one to three unnecessary horses," kept "mainly that they may be available during a few days when the crops were being harvested."

In round numbers, we may say that each horse averaged only 1,000 hrs. worked per year, which is equivalent to 100 days of 10 hrs. each. The cost of feeding horses averaged \$65 per year (1905-1907) in Rice county, \$55 in Lyon county, and \$43 in Norman county. The detailed cost of the feed in Rice county was as follows per horse during 1905 to 1907:

Grain for 4 winter mos., 1,477 lbs. at 0.7 ct.....	\$10.33
Hay for 4 winter mos., 1,924 lbs. at 0.27 ct.....	5.34
Grain for 8 active mos., 3,736 lbs. at 0.33 ct.....	\$3.05
Hay for 8 active mos., 5,149 lbs. at 0.31 ct.....	16.21

Total, 12,290 lbs. \$64.98

The prices for grain and hay were the local market prices less the cost of hauling from the farm to the market. The grain was oats, barley and corn, weighing 32, 48 and 56 lbs. per bushel, respectively. Oats at 0.88 ct. per lb. is therefore equivalent to 27½ cts. per bushel. During the years 1905 to 1907, the average farm prices of farm products throughout Minnesota were as follows: Oats, 31 cts.; barley, 45 cts.; corn, 39 cts.; hay, \$6.27.

The feed per horse per day was as follows in Rice county:

	Winter season. Lbs.	Active season. Lbs.
Grain	13.1	15.4
Hay	15.8	21.3
Total	27.9	36.6

No account was kept of pasturage nor of any straw fed to horses. It is not clear whether the lower price (0.7 ct. per lb.) for grain in the winter season was due to feeding corn instead of oats, or not. It should be noted that the feed during the winter season cost \$3.93 per horse per month as compared with \$6.18 per month during the active season. In Norman county the cost of feed was much lower, due to the practice of feeding very largely with straw in the winter months. The extent to which this was done is well shown by the following records per horse per day in Norman county:

	Winter season. Lbs.	Active season. Lbs.
Grain	6.0	11.4
Hay	6.4	23.4
Total	12.4	34.8

The average annual cost of maintaining a horse in Rice county was estimated as follows:

	Average for 1904 to 1907.	For 1907.
Interest on horse at 5% on de- preciated value.....	\$ 5.54	\$ 6.74
Depreciation (too low).....	5.56	4.35
Harness depreciation.....	2.10	1.39
Shoeing	1.42	1.46
Feed	\$3.49	75.03
Labor	11.88	15.01
Miscellaneous	0.40	0.29
Total	\$90.40	\$104.27

The item of interest is estimated on the average depreciated value of the horse; thus a horse worth \$220 in its prime (4 yrs. old), has a working life of 10 to 15 years, and at the end of that time is worth nothing, hence the interest is estimated on its average depreciated value of \$110.

The bulletin states that the annual depreciation of \$5.56 is too low for an average, and is due to the fact that the increase in the market prices of horses has offset largely the actual depreciation. This method of accounting is fallacious, for fluctuating market values should not be allowed to affect the depreciation charged off annually, for this depreciation charge is really a sinking fund charge intended to return the original investment at the end of the life of the animal. If a \$150 horse has an average working life of 10 years, \$15 should be charged off each year for depreciation, which is \$9.44 more than the average depreciation charge above given. An item that has been entirely omitted is the cost of sheltering. The bulletin estimates this item at about \$6 a year for each cow, which covers its pro rata share of interest, insurance, depreciation and repairs on a barn costing \$80 per head housed. If we add the \$9.44 and the \$6 to the \$90.40 above given, we have a total of \$105 as the average cost of maintaining a horse during 1904 to 1907. The corresponding cost for 1907 would be nearly \$120. Hence, on the basis of 1,000 hours worked annually, the cost of maintenance was 12 cts. per horse per hour in Rice county in 1907. Including cost of housing and a fair allowance for depreciation, there was no county where the average annual cost of maintenance fell below \$100 per horse in 1907. Regarding the assumed depreciation of 10 per cent per year, the bulletin says:

"The experience of many farmers would indicate that the average working life of a farm horse is ten years."

It will be remembered that the feed was charged at its market value less the cost of hauling to market. Strictly speaking this is not correct, but the feed should be charged at its actual cost of production. This cost will next be considered, but, before doing so, it is desirable to record the cost of hired farm labor in Minnesota.

The average monthly cost wage during the "crop season" (8 mo. April 1 to Nov. 31) was \$26.16 in Rice county during 1906 to

1907, to which must be added the cost of board, which was \$14.36, making a total of \$40.50. During the four winter months (Dec. 1 to Mar. 31), the cash wage was \$15.80. This makes an average wage, including board, of \$37 per month throughout the year, or \$444 for the year. As above given, the total number of hours worked per man, including Sundays, was nearly 3,000 hrs. per year. Hence the cost of regular hired farm labor was nearly 15 cts. per hr. in Rice county. The average for the three counties was 12 cts. per hr. In 1907, the cost of board was \$2 more per month than the average of the years 1905 to 1907 in Rice county.

In addition to the regular hired men on each farm; a number of men are employed by the day during the active season, and in 1907, these men received 20 to 25 cts. per hr. including board. Unfortunately no record is given of the percentage of men thus employed by the day, so that it is impossible to state accurately what was the average wage paid to all men, including both classes.

With wages of regular hired men at 15 cts. per hr. worked, and cost of horses at 12 cts. per hr. worked, the cost of team and driver was 39 cts. per hr. in Rice county in 1907, and in no county was it less than 30 cts. It may fairly be assumed to have averaged (in all counties) at least 35 cts. per hr. worked in 1907. If men hired by the day were employed as drivers, the cost was 40 to 45 cts. per hr. for team and driver. These data dispose of Prof. Ira O. Baker's contention that team time on a farm is worth only a fraction of the ordinary rates at which teams are usually hired.

As above stated, the cost of board in Rice county averaged \$14.36 per month per man in 1907, or \$172 per year, or 47 cts. per day. It is not given in detail for any particular county, but the following are typical examples of the daily cost of board on two farms in 1905:

	No. 1.	No. 2.
Food	\$0.181	\$0.190
Fuel and light.....	0.041	0.027
Labor (woman at \$20 per mo.).....	0.171	0.120
Labor (man at about \$35 per mo.).....	0.019	0.012
Total	\$0.412	\$0.349

The higher cost on farm No. 1 is due to the fact that the average number of men boarded was only $3\frac{1}{2}$ as compared with 5 on farm No. 2, thus increasing the daily cost of the labor of household work charged to each man's board.

The cost of producing various crops is given in the bulletin, but unfortunately only the average cost for the period of 1902 to 1907 is given, and not the cost for 1907 also, for wages and prices were considerably higher in 1907, and seem likely to remain so. The costs are given in terms of the acre as the unit, but, as the average amount of product per acre is also given, we can arrive at the cost per bushel or ton. Interest on the land, at 5

per cent, is properly included as a part of the cost. The following is the average cost per acre of hay in Rice county:

	Per acre.
Seed	\$0.293
Mowing (first crop).....	0.362 ✓
Raking (first crop).....	0.178 ✓
Cocking and spreading (first crop).....	0.199
Hauling to barn (first crop).....	1.039
Mowing (second crop).....	0.264
Raking (second crop).....	0.115
Cocking and spreading (second crop).....	0.150
Hauling to barn (second crop).....	0.460
Machinery, interest, deprec. and repairs.....	0.543
Land rental (\$70 at 5%).....	3.500
Total	\$7.178

The cost of the seed per acre was determined thus:

3 lbs. timothy at 3 cts.....	\$0.24
4 lbs. clover at 16 cts.....	0.64

Seed for 2 yrs. at \$0.293 per year.....\$0.88

To the above total of \$7.18 per acre should be added about \$1 for general expense, according to the bulletin, which would give a grand total of \$8.18 per acre of hay. The average yearly production of hay (two crops) was 2.25 tons per acre in Rice county, hence the cost was \$3.64 per ton. The average for three counties was 1.85 tons per acre, hence it is safe to say that the cost averaged not far from \$4 per ton.

It will be noted that there is no item for plowing, the reason being that the hay seed is sown with the grain crop against which the full cost of plowing, etc., is charged. It may well be questioned whether this is correct accounting. The cost of plowing is \$1.25 per acre.

The average farm price for hay in Minnesota was \$6.05 per ton during the period of 1902 to 1907.

The cost of producing oats in Rice county during 1902 to 1907 averaged as follows:

	Per acre.
Seed	\$0.987
Cleaning seed.....	0.023
Plowing (in the fall).....	1.256
Dragging	0.285
Seeding	0.261
Cutting	0.401
Twine	0.325
Shocking	0.165
Stacking	0.772
Stack thrashing (labor).....	0.568
Thrashing (cash cost).....	0.774
Machinery, interest, deprec. and repairs.....	0.517
Land rental (\$70 at 5%).....	3.500
Total	\$9.854

To this should be added about \$1 for general expense, making a grand total of \$10.85 per acre. The average production in Rice county was 41 bu. per acre; hence the cost was nearly 26½ cts. per bushel. The average price of oats in Minnesota was 29.2 cts. per bushel during 1902 to 1907.

The bulletin does not give the average wage paid during 1902 to 1907, but it gives enough data to enable us to say that it was about 12½ cts. per hr. worked, including board. The cost of a horse averaged about 8 cts. per hr. worked, during the same period, on the basis of depreciation assumed (which was confessedly too low) and without any allowance for cost of shelter. But, making proper allowance for depreciation and shelter, the cost of a horse was about 9 cts. per hr. worked. It is clear, therefore, that a team and driver cost more than 80 cts. per hr. worked, during the period of 1902 to 1907.

It should be noted that the farm owner's time was counted the same as an ordinary farm workman, which, as above stated, was 12½ cts. per hr. Obviously this is a questionable procedure. The farm owner is really a superintendent, even though he works with his men, and he is of a grade of intelligence that would command much higher pay than an ordinary workman. The farm owner really gets his pay in the form of "profits." If proper allowance is made for "supervision," it is evident that the costs above given will be considerably increased—probably by at least 10 per cent.

The permanent value of the data in these bulletins would be much greater were the averages made into a sort of composite picture, giving a typical average farm organization thus:

- 1 farm-owner.
- 3 regular hired men.
- 2 extra men (4 extra for 6 mo.).
- 6 work horses.
- 1 woman, household work.

Then the average farm "plant" should be listed, giving prices of each item, including buildings and land, cows, sheep, hogs, etc. Then the total annual product should be itemized, giving actual unit costs per bushel, pound, ton, etc.

Then should follow the unit costs per acre, and these should be tabulated so as to show the amount of work on each item, thus:

Per acre.

Plowing: 1 team and driver, 4 hrs. at 30 cts. \$1.20
 Dragging: 1 team and driver, 1½ hrs. at 30 cts. . . . 0.45

This should be followed by the number of units produced per acre.

The information in these bulletins is excellent, but is not arranged as above indicated, and, therefore, any item of cost on any given farm cannot be compared with another except in terms of dollars and cents, which is often very misleading due to differences in rates of wages. In brief, farm costs should be recorded exactly like engineering construction costs, giving the organization of the working forces, rates of wages, prices of plant, number of hours (or days) of work at stated prices are required to perform each item of work. When recorded in this manner, accurate comparisons are readily made, and correct conclusions drawn.

By way of comparison we add some data taken from the "Encyclopedia Britannica," under the head of Agriculture. There it is stated that during the 20 weeks of active season on the farm,

each horse is fed 16 lbs. of oats and 24 lbs. of hay per day. The annual cost of maintaining a farm horse is estimated thus:

30 weeks' feed (active season) at \$2.75.....	\$ 82.50
22 weeks' feed (inactive season), clover, at \$1.25.....	27.50
Total feed.....	\$110.00
Interest, \$200 at 5%.....	10.00
Depreciation, etc., \$200 at 12½%.....	25.00
Total annual cost.....	\$145.00

The \$200 includes not only the cost of the horse, but its pro rata of farm implements. There was about 1 horse for every 30 acres of farm.

It is stated that unmanured land yields (in 1873) 16 bushels of wheat per acre, but that the application of 400 lbs. of guano per acre doubles the yield. In 1873 the average yield in England was 27 bushels of wheat (82 lbs. per bu.) per acre, an increase of 14 per cent over what it had been 80 years before. The present yield (1909) is about 32 bu. of wheat per acre in England.

In 1873 the following were regarded as being "good crops" per acre:

- 1 ton (2,240 lbs.) of grain plus 2 tons straw.
- 1 ton of beans plus 1½ tons straw.
- 8 tons potatoes.
- 17 tons beets or turnips.
- 35 tons cabbage.

Cost of Maintaining Mules.—Mr. Chas. E. Bowen gives the following data as to costs in 1906 in Alabama.

A first class mule costs \$200. Its useful life is 6 years, at the end of which it will bring \$50. The average cost of maintenance in 7 mines was as follows per mule per calendar day:

Food	\$0.30
Stableman	0.05
Interest and depreciation.....	0.10
Total	\$0.45

The daily ration was as follows:

	Lbs.
Hay	10
Grain	16
Total	26

The U. S. army ration is 14 lbs. of hay and 9 lbs. of grain for a mule, and 14 lbs. of hay and 12 lbs. of grain for a horse.

Due to holidays, Sundays, etc., about 274 days in the year are worked in the mines, hence if all the mules worked the cost would be 60 cts. per mule per day worked. However, about 10% are idle, due to sickness, etc., so that the actual cost per working animal per day is 66 cts., to which must be added 4 cts. for shoeing and harness, making a total of 70 cts., not including any allowance for stable rental.

Mr. E. Hogg says that a mule weighing 1,000 to 1,100 lbs. eats 12 lbs. of grain and 15 lbs. of the best hay per day. He feeds $\frac{1}{2}$ cracked corn and $\frac{1}{2}$ oats, and gives bran twice a week.

Shipping Contractors' Horses in Cars.*—We understand that in the northwest the railroads receive from 14 to 16 horses to be shipped in a stock car, charging the minimum shipping weight, 28,000 lbs., or an average per horse of 2,000 lbs. A 30,000-lbs. capacity car, 30 ft. long, would accommodate this number of horses giving them each about 2 ft. of space.

In the south the writer has been accustomed to ship 20 mules in a car paying for the actual weight of the mules. The length of the car would vary from 30 to 33 ft., thus giving a little over $1\frac{1}{2}$ ft. of space to a mule. In a 36-ft. car 21 or 22 mules could be shipped.

In a palace stock car ranging in length from 54 to 57 ft., the writer has shipped 30 mules, thus giving a space of about 1.8 ft. per mule. A few horses were generally shipped with the mules, but horses cannot be crowded as much as mules can, and at times a separate stall must be built for a valuable horse to keep the mules from crowding or injuring it.

In loading mules into a car a well broken horse is frequently a great help, as mules will follow horses as a rule, and by leading in the horse, several mules can be taken into the car right behind him.

Unless shipped in palace stock cars, animals must be unloaded on a long journey once every 24 hours, so as to be fed and watered. The help of a horse in taking the mules in and out of a car is of great assistance, and saves much time. Railroad companies allow at least one care-taker to accompany a shipment of horses or mules, and he is a busy man when the time arrives for feeding the stock.

Hauling Heavy Machinery on Wagons.—In hauling cement and coal to the Spiers Falls Dam from Glens Falls, N. Y., I found the average load was 2 net tons per team of horses. The loads ranged from 3,500 to 4,500 lbs. The haul was 9 miles, one way, and a round trip constituted a day's work. Teamsters were paid by the ton. The road was sandy, but level, except for about half a mile at the end. Two teams were hitched onto a wagon to pull up this hill at the end.

Some very heavy pieces of machinery were hauled on wagons. One piece of machinery weighing 14 tons was slung between two heavy timber beams whose ends rested on bolsters on the wagons. Thus the piece of machinery was really slung between two wagons, one wagon in front and one behind. In order to steer the rear wagon a simple steering gear was made, very much like the steering device for controlling the rudder of a ship. It consisted of a pilot wheel mounted at the forward end of the rear wagon, and a drum from which two ropes passed around pulleys to the stub tongue of the wagon. One man could thus steer the front wheels

**Engineering-Contracting*, Sept. 25, 1907.

of the rear wagon. With 12 horses this 14-ton load was hauled over the sandy road.

A heavier load, 28 tons, was not loaded on wagons, but was hauled on rollers, a temporary timber way being laid in front of the rollers, as in house moving. It took 18 teams 9 days to haul this load the 9 miles.

Handling Teams With a Jerk Line.^{*}—Mr. W. A. Gillette is author of the following:

I have been especially impressed with the difference between the extreme West and East in handling teams. When I did construction work in the East, I did as Easterners do, namely, submitted to the dictation of teamsters in the determination of each driver to drive his own team. Consequently, when we wanted to use three or four teams on a road grader or plow, three or four teamsters walked along, not driving but "herding" the teams. Once in a while we could find a man who could drive four horses, but not often; and, when he knew how, he wouldn't do it.

Consider what it means to a contractor to have three extra drivers on a plow, drawn by four teams and two extra drivers on a road grader drawn by three teams. It is just as ridiculous as having two men loading wheel scrapers. Five extra men on an outfit as mentioned above means \$7.50 a day, drivers' wages being \$1.50 a day.

In the West we use one driver for one, two, three, four, five or more teams, and these drivers will handle three, four or more teams with one rein or jerk line with as much ease as the ordinary driver handles one team. It is a comparatively simple matter to train these teams to respond to a jerk line, and to the shout of "gee" or "haw."

For the benefit of those who do not know how to hitch a jerk line, I will explain. It is customary to use a strong braided clothes line. This line reaches from the "nigh" wheel animal to the "nigh" lead animal, and is fastened to the left hand side of the bit; from this main line a short piece of the line passes under the jaw to the right side of the bit, making a "Y." Fastened to the hames on the right side of the "nigh" lead is a "jockey stick" (a short piece of wood or iron) which reaches to a curb strap fastened to the bit of the "off" lead animal. A straight pull on the jerk line pulls the "jerk" line or "nigh" animal to the left, or "haw," and the "jockey stick" guides the "off" animal. A succession of jerks on the line causes the "nigh" or left lead animal instinctively to throw its head to the right, to escape from the jerking, and the "jockey stick" guides the "off" animal to the right also, or "gee."

A little patience will teach the lead team to "gee" or "haw" if the guiding words "gee" or "haw" are shouted every time the line is used. By fastening the following teams to the double trees of the team ahead, they will soon learn to follow the team ahead without being tied, and, as a matter of fact, it is not as handy in turning around if each team is fastened, as it does not

^{*}*Engineering-Contracting*, Apr. 14, 1909.

permit them to cross over and out of the way of the chain while turning.

When a team has been properly trained in turning to the right or "gee," for example, the teams following the lead teams will step over on the left of the draft chain and follow it around until the chain is straight for the return trip; then each animal will cross over to his place on the right side of the chain.

In all of our team work we use but one driver, no matter how many teams are hitched to the load. In the hauling of gravel, sand or broken stone we use two or three wagons in a train. The trail wagons have a short trail tongue just long enough to permit the wheels to clear about three or four feet. The economy of this method of teaming is apparent when one driver is used to handle three wagons with three teams, for the wages of two teamsters are saved.

Cost of Plowing Farm Land With a Steam Traction Engine.*—It is only within the last ten years or so that the feasibility of plowing with traction engines has become generally recognized. The results obtained have been very satisfactory, and when it is remembered that one man with a plowing outfit can do much more work than six or eight with horses, the advantages of this method on the large farms of the West are obvious. Some data on the cost of steam plowing taken from letters written to the manufacturers by users of the traction engine are given below.

The first piece of work for which data are given was done in Missouri last year, a 20 hp. Rumley Standard traction engine and an 8-gang 14-in. Moline steam plow being used. An average of 18 acres per day was plowed, the cost of operating per day being as follows:

	Total.	Per acre.
Engineering	\$ 3.00	\$0.166
Water and fuel, hauled with team.....	2.50	0.139
Plowman	1.00	0.055
Coal	3.00	0.166
Plow sharpening, oil, etc.....	0.50	0.027
Total	\$10.00	\$0.553

The next piece of work was done in North Dakota, a 30 hp. Rumley engine and Emerson 14-in. plow being used. The cost was as follows:

	Per acre.
Coal, at \$8 per ton, 90 lbs. per acre.....	\$0.27
Cylinder oil, at 40 cts. per gallon.....	0.01½
Machine oil, at 20 cts. per gallon.....	0.01
Fireman, \$2.50 per day.....	0.06½
Water, team and man for hauling, \$4 per day..	0.10
Sharpening lays.....	0.01
Gear grease, 4 cts. per lb.....	0.00½
Total	\$0.47

It will be noted that there is no allowance made for engineer in the above, the owner of the outfit probably acting as such.

**Engineering-Contracting*, June 16, 1909.

Charging this item up at \$4.00 per day would bring the cost per acre to 67 cts. The fireman also probably acted as plowman. The outfit traveled $2\frac{1}{4}$ miles per hour, cutting $16\frac{1}{2}$ ft. wide, thus averaging four acres per hour, allowing for stops.

The last piece of work was also done in North Dakota, a 30 hp. Rumley plowing engine being used. The ground was stony and hilly and a disc plow with 14 discs and cutting 11 ft. wide was used for breaking the ground. An average of 16 acres of ground was broken per 12-hour day, the cost being as follows:

	Total	Per acre
Coal, 2,800 lbs., at \$7.50 per ton.....	\$ 8.05	\$0.50
Water, team and man for hauling.....	4.50	0.28
Engineer	3.00	0.11
Plowman (who also fired).....	2.00	0.12
Oil and incidentals.....	1.00	0.06
Total	\$18.55	\$1.07

Later on this ground was put in shape for the drill at a cost of about 50 to 60 cts. per acre. To do this the traction engine was used to three sections of 21 discs cutting 18 ft. wide with a large drag and float behind.

None of the above costs include interest, repairs and depreciation.

Cost of Traction Engine Haulage of Ore.*—The hauling of crude ore from its mines in Lemhi County, Idaho, to Dubois, on the Oregon Short Line Ry., a distance of 85 miles, is being done with traction engine trains by the Gilmore Lead Mining Co., Ltd., and the following statement of the method and cost of operating these trains has been furnished by Mr. Robert N. Bell, State Inspector of Mines, Boise, Idaho. Formerly, it may be noted, the hauling was done by teams at a cost of from \$10 to \$12 per ton.

The train consists of four wagons or cars of steel and of 15 tons capacity each and a 110 hp. traction engine. The route is over a flat plain of fine gravelly soil and small sage brush, crossed by a number of creeks and irrigating ditches which are bridged. The road never gets very muddy and dries out rapidly as soon as the snow goes. There is one hill of about 10 per cent grade and three-quarters of a mile long approaching the mine; the engine handles one loaded or four empty cars on this hill. It also sets the cars one at a time at the loading bin on a 15 per cent grade. The coal used in making the trip amounts to about 4 tons per 24 hours, and is distributed in bins at intervals along the route. Water is available about every 15 miles, for which distance the tank capacity of the front car is sufficient.

The following costs of haulage are based on the records of the first trips made with the road practically in its virgin condition. A round trip took four days, working two 12-hour shifts per day and travelling 24 hours per day, with a total load of 40 tons.

**Engineering-Contracting*, May 29, 1907.

	Per shift.	Per trip.	Per ton.
1 engineer at \$6.....	\$ 6.00	\$ 48.00	\$1.20
1 fireman at \$4.....	4.00	32.00	.80
1 swamper at \$3.50.....	3.50	28.00	.70
Total labor.....	\$13.50	\$108.00	\$2.70
Coal	3.00	12.00	0.30
Grand total.....	\$16.50	\$120.00	\$3.00

Cost of Handling and Screening Cinders.—Cinders are often used in concrete and for other purposes. The following data are given by Mr. Ernest McCullough:

The cost of unloading and screening soft-coal locomotive cinders for a filter bed was as follows: The filter bed consisted of a lower layer of cinders 27 ins. thick and an upper layer 9 ins. thick. The lower layer comprised all cinders that would pass a screen of 1-in. mesh, but that would not pass a $\frac{3}{8}$ -in. mesh. The upper 9-in. layer would pass a $\frac{3}{8}$ -in. mesh, but not a $\frac{1}{2}$ -in. mesh. Unscreened cinders were shipped in gondola cars holding about 32 cu. yds. each, and were unloaded near the filter bed, screened and conveyed in wheelbarrows to place. The freight on car load was about \$26. In one shipment of 16 cars there were 2 cars of ashes so fine as to be rejected without screening. The others gave the following proportions:

	Per cent.
Clinkers not passing 1-in. mesh.....	10
Cinders passing 1-in., but not passing $\frac{3}{8}$ -in. mesh..	75
Cinders passing $\frac{3}{8}$ -in., but not passing $\frac{1}{2}$ -in. mesh..	5
Fine dust, under $\frac{1}{2}$ -in.....	10
Total	100

It was found that cinders in a pile exposed for two weeks to the rain and weather were so disintegrated that 33% would pass a $\frac{3}{8}$ -in. mesh.

One man, using a coal scoop, would unload 32 cu. yds. from a car in 10 hrs., and as this yielded about 24 cu. yds. of coarse screened cinders, the cost of unloading was 6 cts. per cu. yd., wages being \$1.50 a day. Another man, using a scoop, would shovel the cinders upon the first (1-in.) screen at the same rate. But it took two men, using ordinary square pointed shovels, to screen through the $\frac{3}{8}$ -in. screens, and these men screened the material twice, because it would not pass through these screens rapidly, nor at the first screening. A fair estimate of the cost of unloading and screening the coarse (1-in. to $\frac{3}{8}$ -in.) cinders is as follows, the cinders being measured in place in the filter bed:

	Per cu. yd.
Unloading cars.....	\$0.06
Coarse (1-in.) screening.....	0.06
Fine ($\frac{3}{8}$ -in.) screening twice.....	0.24
Wheeling and spreading in bed.....	0.08
Total	\$0.44

The freight was about \$1.50 per cu. yd. of screened cinders, and the cost of loading the cars about 16 cts. more, making a grand

total of \$2.10 per cu. yd. of coarse screened cinders in place in filter beds.

Since all the cost of loading, unloading and freight has been charged to the coarse cinders, the cost of the fine cinders ($\frac{1}{8}$ to $\frac{1}{4}$ -in.) was merely the cost of screening them twice through a $\frac{1}{4}$ -in. screen, or 24 cts. per cu. yd. plus 8 cts. for wheeling and spreading. When these fine cinders were perfectly dry, once over the $\frac{1}{4}$ -in. screen was enough; but, if very wet and largely dust, screening three times over the $\frac{1}{4}$ -in. screen was necessary.

Since the proportion of fine screenings ($\frac{1}{8}$ to $\frac{1}{4}$ -in.) was so small, it was necessary to buy a number of car loads of screenings and waste all the material over $\frac{1}{4}$ -in. size. The freight, when charged against the fine screenings, was about \$12 per cu. yd. due to the fact that not more than 3 cu. yds. of fine screenings could be obtained from a car load. An attempt was made to grind up some of the coarse screenings using a farmer's feed mill operated by horsepower. The mill would grind at the rate of $7\frac{1}{2}$ cu. yds. of cinders in 10 hrs., but so many iron bolts and nuts were in the cinders that the mill was continually forced to stop, and finally had to be abandoned.

The specific gravity of soft coal cinders is 1.5, and the voids are frequently as high as 60%, in which case 1 cu. ft. of cinders weighs $37\frac{1}{2}$ lbs.

Size, Weight and Price of Expanded Metal.—The following are standard sizes of expanded metal:

Mesh.	Gage of Metal.	Width of Metal.	Sectional area per ft. of width.	Lbs. per sq. ft.
3-in.	No. 10	$5/32$ in.	0.185 sq. in.	0.65
3-in.	No. 10	$15/64$ in.	0.278 sq. in.	0.94
3-in.	No. 10	$5/16$ in.	0.370 sq. in.	1.25
6-in.	No. 4	$1/4$ in.	0.259 sq. in.	0.86
6-in.	No. 4	$3/8$ in.	0.389 sq. in.	1.29

The 3-in. mesh is sold in 6 x 8-ft. sheets; the 6-in. mesh in 5 x 8-ft. sheets; and in both cases, 5 sheets per bundle. These are the common sizes, but expanded metal of the following meshes is also made; $\frac{1}{2}$ -in., $\frac{3}{4}$ -in., $1\frac{1}{2}$ -in., and 2-in. The mesh is measured the short way across the diamond.

Expanded metal is sold by the square foot, but at prices equivalent to about 5 to 6 cts. per lb., depending upon the locality and the size of mesh. For expanded metal lath see index under "Lath, Metal."

Price of Mineral Wool.—Mineral wool is ordinarily made by pouring molten slag into water. It is largely used as a filling in hollow walls, because of its heat insulating property. I have also used it as a packing around water pipes that were exposed to the air. In carrying a pipe line across a bridge, for example, the pipe may be laid in a box and surrounded with mineral wool. A steam pipe may be jacketed in the same way.

Ordinary mineral wool weighs about 12 lbs. per cu. ft. and may be bought for about 1 ct. per lb.

Cost of Sodding.—Mr. Arthur Hay gives the cost of sodding a park in Illinois. The best sod shovel is a "moulder's shovel," with

a flat blade 10 ins. wide and 12 ins. long. The edge should be drawn down thin on an anvil and sharpened on a grindstone. The sod is cut through in parallel lines 14 ins. apart, with the shovel held at an angle so as to give bevel edges to the roll of sod. The sod strip is cut off square at the ends so as to make a strip about 8 ft. long (a square yard), and rolled up. One hundred of these rolls make a good wagon load, 80 being about the usual load. Sod should be cut as thin as possible, say $1\frac{1}{2}$ to 2 ins. thick. Sod cut thicker, with the idea of saving all the roots, never unites with the bank when laid on an earth slope. When the rolls are laid, fine earth should be sifted into any cracks between the rolls. The sod should be thoroughly soaked with water after it is laid, and tamped to expel air underneath. A good tamper, or spatter, consists of a piece of 2-in. oak plank 10 ins. wide by 18 ins. long, strengthened by cleats across the ends and with a tough wood handle 2 ins. in diameter and 4 ft. long. One end of this handle is beveled off and bolted to the plank so that when the plank lies flat on the ground the end of the handle is waist high.

The following was the average cost of laying 20,000 sq. yds. of sod by day labor for the city of Springfield, Ill.:

	Cts. per sq. yd.
Cutting sod.....	1.6
Hauling sod.....	0.9
Laying sod.....	2.6
Watering sod.....	0.6
Spatting sod.....	0.1
Total	5.8

Men were paid \$1.50 per 8-hr. day, and the sod cutters had a theory, very difficult to contend with, that 71 sq. yds. should constitute a day's work. Average contract prices in the vicinity were 10 cts. per sq. yd. of sod in place.

Seeding can be done for about \$20 an acre, the cost of 80 lbs. of seed being \$10, and the cost of labor being about \$10 more. On slopes gentle enough to hold the seed without washing, seed is preferable to sod on account of its cheapness. An acre of sod, at 6 cts. per sq. yd., would cost about \$300.

A Device for Cutting Soil for Sodding.*—Mr. A. N. Tolman gives the following:

Fig. 8 shows a sod cutter used at Sioux Falls, S. Dak. The construction is clearly shown by the illustration, but it may be well to add that the knife is curved (in plan) and pitches downward about $\frac{3}{4}$ in. in its width of $2\frac{1}{2}$ ins. It can be adjusted so that the sod can be cut in different thickness as required. I have not seen the cutter in use but two men and a boy with a team cut enough sod to load a flat wagon ($1\frac{1}{4}$ cu. yds.) and rolled the sod and loaded the wagon in a trifle over an hour. This was so much faster than I had anticipated that I arrived on the scene only in time to find that the loaded wagon was more than the team could haul on

**Engineering-Contracting*, Aug. 11, 1902.

the muddy road. As the cutter is easily and cheaply made, and evidently a great improvement on the spade, it may be of interest to your readers.

Painting Data.—A gallon of iron oxide paint will cover 400 sq. ft. of wood surface, or 500 sq. ft. of iron surface, first coat. It requires about two-thirds as much paint for the second coat as for the first; and half as much paint for the third coat as for the first. Further data will be found on page 558.

A man, working 9 hrs. can paint (one coat) 2,000 sq. ft. of tin roof, or 1,000 sq. ft. of frame house, or 300 sq. ft. of bridge trusses. The shifting of scaffolds on house work accounts for the

Fig. 8.—Sod Cutter.

decreased time; and the smaller area of the surfaces of bridge trusses makes the work slower in bridge painting.

Consult the index under "Painting."

Cost of Painting a Tin Roof.—Mr. J. M. Braxton gives the following:

An old tin roof was showing rust spots, most of the paint being worn off. The tin was first rubbed with palmetto brushes and then swept clean. The area painted was 151,000 sq. ft., requiring 563 gals. of paint for two coats, or 267 sq. ft. per gallon for the two coats. The paint was:

396 gallons raw linseed oil.

35 lbs. dryer.

2,120 lbs. dry oxide of iron.

This mixture yielded 563 gals. of paint. Each man averaged 1,920 sq. ft., or 320 sq. yds. per day of 8 hrs. painted with one coat. It took 158 man-days to paint the roof, not including foreman's time.

Unloading Coal From Cars With a Clamshell.*—Broken stone, sand and gravel can be unloaded from cars very cheaply with a clamshell bucket, wherever the amount to be handled warrants the use of such a plant. The following data on unloading coal may also be applied to handling other materials.

At the Navy Yard at Washington, D. C., a locomotive crane, fitted with a 50-ft. boom and a $1\frac{1}{4}$ -cu. yd. Hayward clamshell bucket has been in use for unloading coal from cars. A description of the crane is as follows: Track gage, 4 ft. $8\frac{1}{2}$ in.; wheel base, 8 ft.; greatest width, 9 ft. 10 in.; maximum working radius, 20 ft.; hoisting speed per minute, 250 ft.; rotating speed, three revolutions per minute; traveling speed, 350 ft. per minute; capacity, one trip per minute. The machine will lift 20,000 lbs. at a 12-ft. radius, and 7,500 lbs. at a 30-ft. radius. The engine is a 9 x 12-in., double cylinder, double drum engine, fitted with the necessary clutches and brakes for controlling the swinging and propelling movements of the machine. The crane was manufactured by the McMyler Mfg. Co., of Cleveland, O.

According to data furnished by Mr. F. E. Beatty, commandant of the Washington Navy Yard, the machine will unload approximately 400 tons of coal in eight hours. The crane used in loading coal cars from the coal bin will dip and load 48 tons in 10 minutes. In unloading a car, the bucket easily takes out three-fourths of the contents of the car. The remainder of the coal is taken into the boiler house by opening bottom run to bunkers with a chute, and thus requires no rehandling. In unloading the coal, one car is ahead of the crane, and the other behind, on the same track. The bucket takes a load, and, without stopping the swing of the boom, the coal is dropped; then the second car is reached, and the bucket filled. Commander Beatty considers that this makes not only less work for the man handling the levers, but also increases the output by 10 to 15 per cent.

A clamshell bucket is also used at the Polk street plant, Chicago, of the Western Electric Co., in handling coal from cars to storage bin. In this case, however, the bucket is operated by an electric overhead traveling crane. This machine was built by the Whiting Foundry & Equipment Co., of Harvey, Ill., for the Western Electric Co. It is of the three-motor type, and has a working load capacity of 10,000 lbs. The span, center and center of runway rails is 73 ft. 10 in. The lift (maximum vertical travel of hook) of the main hoist is 37 ft. The average travel is 50 ft. A 2-cu. yd. Hayward clamshell bucket is used.

Mr. G. A. Pennod, factory engineer for the General Electric Co., states that a 40-ton car can be unloaded in $1\frac{1}{2}$ to 2 hrs., depending on the travel of the crane. From 5 to 6 cars a day, allowing for

**Engineering-Contracting*, May 23, 1906.

switching, etc., can be unloaded in a day. It takes two men to unload a car; one man to operate the crane, and one man to shovel what coal remains in the corners of the car which the bucket, on account of its bulky nature, cannot pick up.

This last operation takes about as much time as unloading with the bucket alone, that is, the bulk of the coal in a 40-ton car can be unloaded in about 45 minutes, and it takes the same length of time for one man to shovel out what remains. The time of this last operation can, of course, be reduced by putting on more men.

If we assume that a man shovels coal at the rate of 4 tons per hour, it is evident that the clamshell bucket removes all the coal in a car except about 3 tons which must be shoveled out by hand.

It is apparent from the two foregoing examples that a contractor need not be afraid that a clamshell bucket will not clean up a carload of broken stone sufficiently well for practical purposes.

For data on handling stone with clamshells, consult the index under "Clamshell."

Cost of a 28-Mile Telegraph Line.*—The data to be given relate to a telegraph line 28 miles long, built in British Columbia. There were 32 poles to the mile, strung with a single No. 8 B. B. galvanized iron wire. The cost of the poles was very much less than it would be in most localities, but, since quotations on poles are readily secured, proper substitutions can be made in the following tabulated values for any particular case.

Regarding telegraph wire, a word of explanation may be helpful. Until recently the size of wire commonly used for lines of medium length, up to 400 miles, was No. 9, weighing 305 lbs. per mile, but No. 8 is now used more frequently. There are two grades commonly used: The E. B. B., or "extra best best," and the B. B., or "best best." A third grade, B, or "steel," is also used for short circuits. The following are the weights of galvanized wire:

		Lbs. Per mile.	Lbs. Per ft.	Ft. Per lb.
No. 6.....		570	0.108	9.2
No. 7.....		450	0.085	11.7
No. 8.....		390	0.072	14.0
No. 9.....		305	0.058	17.4
No. 10.....		250	0.047	21.2

The itemized cost of this 28-mile line was as follows:

Labor:	Per mile.
1.0 day, foreman at \$3.50.....	\$ 3.50
1.0 day, sub-foreman at \$3.00.....	3.00
2.7 days, climber at \$2.50.....	6.75
2.5 days, framer at \$2.25.....	5.62
0.7 day, blacksmith at \$2.25.....	1.58
4.6 days, groundman at \$2.00.....	9.20
12.5 days total at \$2.40.....	\$29.65

**Engineering-Contracting*, July 10, 1907.

Materials:	
22 poles (25-ft.) at \$1.25.....	\$40.00
22 wooden brackets at 1 1/4 cts.....	0.40
22 glass insulators at 0.4 cts.....	1.28
5 lbs. nails at 2 1/4 cts.....	0.12
1/4 lb. staples at 0.3 cts.....	0.02
250 lbs. No. 8 BB galv. wire at 5 cts.....	12.00
2 lbs. tie wire at 3 cts.....	0.06
Total materials.....	\$60.88
Total labor and materials.....	90.53

The labor includes the cost of digging holes, erecting poles, stringing the wire, etc. The poles were distributed by train, and the price of \$1.25 per pole does not include the train service.

A pole 12 in. diameter at the butt and 7 in. at the top, contains 1/2 cu. ft. of wood per lin. ft. Hence there are about 12 1/2 cu. ft. of timber in a 25-ft. pole. Knowing the kind of timber, it is easy to estimate the weight of poles, and consequently the freight for any given haul. If the timber weighs 40 lbs. per cu. ft. the weight of a pole is about 500 lbs. With 22 poles per mile, the weight is 5 tons for the poles. See page 952 for weights of poles.

Cost of a Telephone Line.—In *Engineering-Contracting*, May 27, 1908, an article by Mr. L. E. Hurts gives in detail the methods of building an all-cable telephone plant in a suburb of a city, the population of the suburb being 2,000. The following is the summary of unit costs:

	Cost each.
Poles, unloaded, 262.....	\$0.07
Poles shaved (average, 30 ft. long).....	0.22
Poles roofed (and a very few galls cut).....	0.07 1/2
Poles hauled (average, 30 ft. long).....	0.25
Poles set (average, 30 ft. long).....	0.23
Poles set (average, 40 ft. long).....	0.62
Poles bored for steps.....	0.18
Poles stepped.....	0.20
Pole holes dug, average, 30 ft., pole holes 5 1/2 ft. deep.....	0.47 1/2
Anchors, holes dug, 29.....	0.45
Anchors set, 29.....	0.53
X-arms fitted.....	0.07
X-arms distributed.....	0.09
X-arms put on.....	0.15 1/2
Guys put on.....	1.00
Stringing and pulling messenger, per ft.....	0.00 1/2
Cable pulled, average 25 pr., per ft.....	0.00 1/2
Cable clipped (hangers put on), per hanger.....	0.00 1/2
Staking out line, per pole.....	0.10
Poles pulled and holes filled, per pole.....	0.85
Cable unloaded, average, 25 pr. per ft.....	0.00 1/3
Drops strung, per drop.....	1.04
Bare wire strung, per single wire per mile.....	2.75

Average total cost of labor and material for splicing lead covered, paper insulated telephone cable:

25 pr. cable.....	\$ 3.26
50 pr. cable.....	2.95
75 pr. cable.....	4.40
100 pr. cable.....	5.75
150 pr. cable.....	8.23
200 pr. cable.....	8.37
250 pr. cable.....	10.00
300 pr. cable.....	10.00

Cost of Two Telephone Lines.*—Two short lines were built, one 10 miles long and the other 14 miles long. The cost of the 10-mile line was as follows per mile:

<i>Labor:</i>	<i>Per mile.</i>
1.7 days foreman at \$4.00.....	\$ 6.80
1.7 days sub-foreman at \$3.00.....	5.10
4.0 days climbers at \$2.50.....	10.00
10.5 days groundmen at \$2.25.....	23.63
<hr/>	
17.9 days total at \$3.10.....	\$ 55.53
 <i>Materials:</i>	
28 poles at \$1.50.....	\$ 42.00
28 cross arms at \$0.15.....	4.20
28 steel pins at \$0.04.....	1.12
28 glass insulators at \$0.04.....	1.12
56 lag screws and washers at \$0.015.....	0.84
385 lbs. No. 9 galv. wire at \$0.042.....	12.81
<hr/>	
Total materials.....	\$ 62.09
Total labor and materials.....	117.63

More than 90% of the poles were 25 ft. long. The rest were 30 to 40 ft. in length.

The cost of the 14-mile line was as follows per mile:

<i>Labor:</i>	<i>Per mile.</i>
2.2 days foreman at \$3.50.....	\$ 7.70
2.2 days sub-foreman at \$3.00.....	6.60
5.3 days climber at \$2.75.....	14.58
11.4 days groundman at \$2.25.....	25.64
<hr/>	
21.5 days total at \$2.54.....	\$ 54.52
 <i>Materials:</i>	
32 poles at \$1.50.....	\$ 48.00
32 brackets at \$0.015.....	0.48
380 lbs. No. 8 galv. wire, \$0.042.....	15.96
10 lbs. No. 9 galv. wire, \$0.042.....	0.42
1 1/4 lbs. fence staples, \$0.025.....	0.04
32 insulators, \$0.04.....	1.28
<hr/>	
Total materials.....	\$ 66.18
Total labor and materials.....	120.70
2 telephones at \$12.50.....	25.00
200 ft. office wire.....	1.40

Considering the low cost of telephone lines of this character, it is surprising that they are not more frequently built for use on construction work. For temporary purposes, a much cheaper kind of poles could be used. For example, a very substantial pole could be made by nailing together two 1 x 4-in. boards, so as to form a post having a T-shape cross-section. Such a pole would contain only two-

**Engineering-Contracting*, July 24, 1907.

thirds of a foot, board measure ($\frac{3}{4}$ ft. B. M.) per lineal foot of pole. At \$24 per M for the boards, a pole 20 ft. long would cost 32 cts.

Hence the poles would cost less than \$10 per mile of line. The No. 9 wire would ordinarily cost less than \$13 per mile, and \$3 more would cover the cost of the remaining line materials, making a total cost of \$26 per mile for materials. We have no data as to the labor of erecting such a line, but it would certainly be less than \$15 per mile; and in soil where post hole diggers could be used the cost would be considerably less. In fact, a telephone line built for \$35 a mile might easily be obtained under fairly favorable conditions. Moreover it could be taken down and used many times on subsequent construction. Such a light pole line, however, would not stand up in severe winter weather.

Life of Telephone Line Equipment.*—Some time ago the city of Chicago appointed a special commission, consisting of Prof. Dugald C. Jackson, Dr. George W. Wilder and William H. Crumb, to investigate matters pertaining to the telephone situation in that city. In connection with its report the commission gave the following data as to the life and depreciation of telephone equipment:

Property:	Life in years.....	Per cent to depreciation account	Per cent salvage.	Per cent to reconstruction and insurance.....
Underground conduit, main, clay in concrete..	50	.89	0	1 $\frac{1}{2}$
Underground conduit, main, fibre, etc.....	20	3.72	0	1 $\frac{1}{2}$
Underground conduit, subsidiary.....	20	3.72	0	2 $\frac{1}{2}$
Underground cable, main.....	20	3.72	0	2 $\frac{1}{2}$
Underground cable, subsidiary.....	15	5.38	40	2 $\frac{1}{2}$
Aerial cable.....	15	5.38	0	3
Poles, including crossarms, etc.....	10	3.72	0	4 $\frac{1}{2}$
Aerial strand.....	12	7.05	0	3 $\frac{1}{2}$

Teams, tools, furniture, etc.....	4	22.92	10	0

Vitrified Conduit Data.—Vitrified conduits for carrying electric wires underground are made in single or multiple ducts. A single duct is a pipe 18 ins. long with a round or square bore ranging from 3 $\frac{1}{4}$ to 4 ins. diameter. Multiple ducts are made with two or more ducts in one piece. The common multiples are 2, 3, 4, 6 or 9 ducts in one piece. The lengths of the pieces are 24 or 36 ins. Ducts are sold by the duct-foot, and the present price in New York City

**Engineering-Contracting*, Feb. 12, 1908.

is about $3\frac{1}{2}$ cts. per duct-foot. A 6-duct multiple has 6 duct-ft. per lin. ft., and its price is therefore $6 \times 3\frac{1}{2}$, or 21 cts. per lin. ft. the 6-duct piece. The weight varies somewhat with different manufacturers, but 8 lbs. per duct foot may be used for estimating freight and haulage.

I am informed by one of the large manufacturers that the 9-duct multiple is not so popular as it once was, due to loss by breakage.

The outside dimensions of vitrified conduits are about as follows:

Number of ducts in the piece...	1	2	3	4	6	9
Dimensions of the piece, ins....	5x5	5x9	5x13	9x9	9x13	13x13

These ducts are all square bore, $3\frac{1}{4}$ ins. square with rounded corners.

Cost of Laying Electric Conduits.—My own cost records for this class of work cover only two sizes of vitrified pipe conduits encased in concrete. One of these conduits was made of 4-duct pipe, each duct being $3\frac{1}{2}$ ins. inside diameter, the 4 ducts being baked together in one piece 18 ins. long. First a trench was dug 2 ft. 8 ins. deep and 18 ins. wide, then a bed of concrete 4 ins. thick was laid in the trench. Upon this concrete the conduit was laid, every joint being wrapped with a strip of cheap cotton cloth. Then concrete was packed on both sides of the conduit and 4 ins. thick over its top. The labor cost of laying this conduit, not including the cost of trenching and the cost of making and placing the concrete, was as follows: Two men laying the duct pipe and one helper delivering pipe from piles along the sidewalk, averaged 60 lin. ft. of 4-duct conduit laid per hour, which is equivalent to 120 ft. of single duct per hour. With wages of duct layers at 20 cts. each per hour, and helper at 15 cts. per hour the cost of laying was a trifle less than 1 ct. per lin. ft. of 4-duct conduit, or $\frac{1}{2}$ ct. per ft. of single duct.

In laying a 9-duct conduit (each piece of pipe having 9 ducts instead of 4 as above), two men laying were supplied with pipe by two helpers. This gang averaged 30 lin. ft. of 9-duct conduit per hour, at a cost of 2.3 cts. per lin. ft. of conduit, or $\frac{1}{4}$ ct. per ft. of single duct. From this it appears that the labor cost of laying the pipe is practically the same per duct-foot, whether 4-duct or 9-duct conduit is laid.

At another time, one man laying a single duct line (exclusive of trenching and concreting) averaged 66 lin. ft. per hour, at a cost of a trifle less than $\frac{1}{4}$ ct. per ft. The work in all these cases was done by day labor for the company.

Cost of Vitrified Conduits, Memphis, Tenn.—Mr. F. G. Proutt gives the following data on electric vitrified conduit construction at Memphis, Tenn., in 1903: The work was done by day labor, the wages of common laborers (negroes) being \$1.50 per day. There were about 3,700 ft. of trenches containing 27 ducts, and 7,300 ft. of trench containing 18 ducts, besides which there were 575 ft. of

trench containing from 6 to 40 ducts, making in all 11,475 ft. of trench and 252,000 duct feet. An 18-duct conduit was made up of three 6-duct sections (no single duct sections were used), each section measuring 2 x 13 ins., sections being laid one on top of the other. The ducts were surrounded on all sides with concrete 3 ins. thick, making 6 ins. of concrete, 27 ins. of ducts and 30 ins. of backfill, or a trench $5\frac{1}{4}$ ft. deep for an 18-duct conduit. The width of the duct, 13 ins., plus 6 ins. for concrete, gives a trench 19 ins. wide, or about $8\frac{1}{4}$ cu. ft. (less than $\frac{1}{2}$ cu. yd.) of excavation per foot of trench. The 27-duct conduit was made up of 4 multiple ducts of 6 ducts each, and one multiple of 3 ducts, laid in tiers, making the trench $6\frac{1}{4}$ ft. deep and 19 ins. wide, or about 9.4 cu. ft. per foot of trench. Roughly speaking, all the trench work averaged $\frac{1}{2}$ cu. yd. excavation per foot of trench. All 6-duct sections were 3 ft. long, and all 3-duct sections were 2 ft. long.

The executive force consisted of 1 general foreman at \$3; 1 foreman of pipe layers; 1 foreman of concrete mixing gang; 1 foreman in charge of digging for manholes; 1 foreman in charge of backfilling and hauling away, and 1 timekeeper. There were 8 men on manholes and service boxes, 80 men trenching, concreting and pipe laying. The best day's work was 703 ft. of trench and 15,156 duct-feet.

In laying the ducts, the 3-in. concrete bottom was first placed, then 2 men in the trench laid the lower tier or run, 2 men on the bank handling the sections down by means of a rope run through one of the holes. This run was followed by a similar gang of 4 men working a few lengths back. Three dowel pins were used in each section. The joint was made with a strip of cheap canvas 5 ins. wide by 5 ft. long laid on the bottom before placing the ducts. A boy followed along, wrapping the canvas over the top joint and painting the lap with asphaltum. To cut the canvas into strips a table was made with a saw kerf in it 5 ins. from one edge and at this edge was a strip against which to push the bolt of cloth. A large butcher knife was then run through the saw kerf and cloth, cutting off a strip 5 ins. wide and the length of the bolt. This strip was wound on a reel whose circumference was 5 ft., and a cut through the cloth at the circumference made strips 5 ft. long.

The concrete was mixed with "Dromedary" mixers costing about \$200 each. A "Dromedary" mixer holds about $\frac{1}{2}$ cu. yd. of concrete, and is hauled by two horses in tandem. Half the charge of sand is shoveled in, then the cement, then the rest of the sand, and finally the stone. The door is closed and the mixer hauled about 150 ft. to the water tank and from 6 to 8 pails of water are thrown in. If the concrete must be rehandled the mixer is hauled to a dumping board 3 ft. wide by 24 ft. long, made in two 6 x 12-ft. sections.

The cost of 252,000 duct-feet, laid in 11,475 ft. of trench, was as follows:

254,500 duct feet (1% broken), at 5½ cts.....	\$12,997
45 cars of ducts unloaded, at \$7.50.....	338
Labor trenching, backfilling, concreting and duct laying	7,745
Materials for 881 cu. yds. of 1:4:8 concrete,* at \$5.22.....	4,604
32 brick manholes,† at \$115.....	3,680
31 manhole drains,‡ at \$36.....	2,866
48 service boxes,§ at \$30.....	1,520
4,200 lin. yds. canvas (5 ft. wide), at 5 cts.....	215
5 bbls. asphalt paint, at \$30.....	150
40,000 dowel pins for ducts, at ½ ct.....	200
Tools	300
City water.....	50
Plumbers repairing water pipes.....	100
New sidewalks.....	600
Repaving city streets.....	1,000
City inspection.....	155
Engineering	1,000
Incidentals	1,140
252,000 duct feet, at nearly 16 cts.....	\$40,000

*Each cubic yard of 1:4:8 concrete required 0.96 bbl. (a bbl. being counted as 4 cu. ft.) cement at \$2.10 per bbl.; 0.56 cu. yd. of sand at \$1.25 per cu. yd.; and 1.26 short tons of broken limestone at \$2 a ton.

†Each manhole was 3-sided, 5 ft. wide by 7 ft. long and 6½ ft. deep, inside measure, with 12-in. brick walls, a 4-in. concrete floor, and a 12-in. concrete top reinforced by old rails. There were 3,206 bricks in each manhole at \$7.50 per M; there were nearly 4 cu. yds. of concrete in the bottom and top at \$5.75 per cu. yd. for materials. Masons were paid \$6 a day and helpers \$2. The cost of excavating for and building a manhole averaged about \$40. The iron rails cost \$5. The cast-iron cover for each manhole weighed 1,150 lbs. costing 1.9 cts. per lb.

‡Manhole drains averaged 170 ft. long of 6-in. sewer pipe, costing \$10 for materials and \$76 for labor.

§Service boxes contained 325 bricks each, and were 3 ft. square inside, with 9-in. walls, and provided with cast-iron covers like the manhole cover.

The designs of manholes, methods of construction and other details as to this work are given in Mayer's "Telephone Construction—Methods and Cost," p. 243 et seq.

Cost of Brick Manholes for Electric Conduits.—Square manholes were built with brick walls 12 ins. thick. The bottom of the manhole was concrete, and the top was reinforced concrete. The following data relate only to the brick work: Each manhole contained 4.6 cu. yds. of brick masonry, and the following gang averaged 1½ days to each manhole, the day being 8 hrs. long:

2 masons, at \$3.00.....	\$ 6.00
3 helpers, at \$1.50.....	4.50

Total per day.....\$10.50

Therefore, it cost \$12.35 per manhole for the labor on the brick work, which is equivalent to \$4 per cu. yd. of brick masonry. Since each manhole contained 2,140 bricks, each mason averaged about 640 bricks laid per 8-hr. day. This was very slow work. It was done by day labor for a company. See Mayer's "Telephone Construction—

Methods and Cost" for the design, methods of construction and itemized costs of several hundred brick and concrete vaults.

Methods and Cost of Laying Vitrified Conduits for Electric Wires.*—Considering the large amount of vitrified conduit work that is being done, there is surprisingly little in print on the cost of laying conduits for electric wires. In our issue of July 11 we gave the costs of excavation and of concrete work on the Atlantic Ave. subway work of the Long Island R. R. The concrete retaining walls of that subway contained many thousand feet of vitrified ducts, and we give herewith some data bearing upon the cost of hauling and laying the ducts for the electric wires. The ducts were of standard 3-ft. length, having an inside diameter of 3¼ ins. Multiple duct conduits were laid, being for the most part, 4-hole pieces.

The conduits were unloaded from boats, hauled about 1½ miles, and piled up ready for use. The cost of unloading, hauling and piling was 0.8 ct. per duct-foot; and, as a duct-foot weighs about 8 lbs., this is equivalent to \$1.30 per ton. Laborers received 15 cts. an hour, team and driver 45 cts.

The cost of laying conduits during the year of 1903 was as follows:

	Duct-ft. laid.	Labor, days	Pay roll.	Cost per duct ft.
January	1,942	10	\$ 15	0.8 ct.
February	1,626	9	13	0.8 ct.
April	4,512	32	55	1.2 ct.
May	30,653	154	254	0.8 ct.
June	27,715	205	357	0.9 ct.
July	27,893	179	288	1.0 ct.
August	15,293	92	142	0.9 ct.
September	14,170	63	108	0.8 ct.
October	10,037	43	74	0.7 ct.
Total.....	143,851	787	\$1,316	0.9 ct.

From this it appears that the cost of laying was a trifle less than 1 ct. per duct-foot, and that the average wages were \$1.66 per day of 10 hrs. This is the average of the common laborers delivering ducts and the skilled men laying ducts.

It required 150 bbls. of Portland cement to lay the 143,851 duct-feet, or 1 bbl. per 960 duct-feet.

During the year of 1904, there were 227,600 duct-feet laid, requiring 240 bbls. of cement and 975 days labor. The average wages paid were \$1.71 per day, and the average cost was 0.8 ct. per duct-foot for laying. During the best month, 30,700 duct-feet were laid at a cost of 0.6 ct. per duct-foot for laying, which indicates that the workmen were not very efficient during the previous months.

In our February issue we gave the itemized cost of building a section of the New York Subway, and from that article we have ab-

**Engineering-Contracting*, July 25, 1906.

abstracted such data as pertain to conduit construction, for the purposes of comparison, as follows:

	Per duct-ft.
Labor	1 ct.
Materials	5 cts.
Total	6 cts.

The cost of materials for 123,483 duct-feet in the New York Subway were as follows:

123,483 duct-ft., at 4½ cts.....	\$5,556
6,000 sq. yds. burlap, at 4½ cts.....	270
275 bbls. Portland cement, at \$1.52.....	426
62 cu. yds. sand, at \$0.50.....	31
12 sets mandrels, at \$2.....	24
Total, 123,483 duct-ft., at 5 cts.....	\$6,321

One barrel cement was used for every 440 duct-feet.

As an average of a large amount of work on the New York Subway, the following data were deduced: 100 duct-feet require 0.32 bbl. cement, 0.055 cu. yd. sand and 4.86 sq. yds. burlap. The conduits used were 4-hole pieces in 2-ft. lengths, 3 ins. square, built up in advance of the concrete side walls which surrounded them.

On another section of the New York Subway where more than 500,000 duct-feet were laid, the cost of the labor of laying was 1½ cts. per duct-foot. And on still another section, where 60,000 duct-feet were laid, the cost was as high as 2½ cts. per duct-foot for labor of laying. This last appears to indicate an immense amount of loading; although the New York Subway work at best was poorly managed by the contractors.

However, the wages paid on the New York Subway work were high, being \$5.20 per 8-hr. day for the bricklayers who laid the ducts. We are informed that the men who handed the ducts to the layers were classed as "mason's helpers," in which case they would have received about \$3 a day, being union men. But in the itemized list of workers and wages of men on the New York Subway, given in our February issue, we find no "mason's helpers." This makes it doubtful whether the helpers were credited as receiving more than the wages of common laborers, or \$1.50 a day.

In laying the ducts, there were sometimes 2 helpers to 1 bricklayer, sometimes 2 helpers to 2 bricklayers. It was the duty of one of the helpers to prepare the muslin sheets that were wrapped around the joints of the ducts. The sheets were cut into strips 8 ins. wide and 3½ ft. long; then they were laid on boards and soaked with neat cement grout, using a whitewash brush for the purpose. This helper sometimes passed the cemented cloths to the layer; but sometimes a helper passed the cemented cloths and the ducts to the layer.

The conduits were laid 16 ducts high, usually back of the steel side columns and against the waterproofed 4-in. backing wall of brick on each side of the subway. The ducts were laid to break joint, with a cemented cloth around each joint, then a little mortar was slushed in to smooth up the line of ducts. Mandrels were used in laying, the mandrel being 4 ft. long, and extending through two ducts.

The specifications for this Long Island R. R. work are given in Mayer's "Telephone Construction—Methods and Cost," p. 278 et seq.

Cost of Pole Lines, Vitrified Conduits, Manholes, Etc.—References.—A complete treatise on the methods and cost of telephone line construction, with data equally applicable to electric power transmission lines, is Mayer's "Telephone Construction—Methods and Cost." The cost data were secured from work aggregating 50 miles of underground conduit, and the pole line costs cover an even more extensive mileage. The same book contains other similar data gathered by Mr. J. C. Slippy.

Labor Cost of an Electric Transmission Line.—In *Engineering-Contracting*, Feb. 5, 1908, two pages are devoted to the methods and cost of constructing a 20-mile electric power transmission line. A full abstract of the same is given in Mayer's "Telephone Construction—Methods and Cost," p. 227 et seq. The following is merely a brief summary of the labor cost per mile of line:

	Per mile.
Hauling poles	\$ 18.75
Digging (46 poles) holes.....	45.47
Raising poles	35.47
Dapping crossarms	14.14
Hauling and placing crossarms and insulators..	21.01
Labor on guy poles.....	18.28
Trimming trees and bushes.....	20.94
Stringing and fastening wires.....	74.06
Changing old poles.....	35.31
Total	\$283.42

Laborers received \$1.50; linemen, \$2.50; teams, \$4.50. The poles were 32 ft. long, set 5 ft. deep. There were two crossarms to a pole, each holding 8 pins; but a third dap was made in each pole to provide for a future crossarm. Twelve wires were strung.

Cost of Transmission Line for Interurban Electric Railways.*—The following is a rather brief abstract of an article by Mr. E. P. Roberts and Mr. J. C. Gillette:

The following data on overhead line construction for interurban electric railways are based on actual practice and on the average costs of a large number of lines in different sections of the United States. The elements of interurban electric railway overhead line construction are: (1) A conductor from which the cars take electrical energy, and (2) the supporting of this conductor, which may be directly by brackets or by cross spans, which in turn are supported by poles. These two methods of construction are termed respectively bracket suspension and cross-suspension. The trolley wire may be supported either directly from insulators carried by the brackets or spans, or by steel cable, which in turn is supported by the brackets or spans. The former is the old and standard method of trolley construction so long used on direct current lines, while the latter is the new "catenary" type of construction. The work for a 600-volt direct current line will be considered first and then the work for a line for higher voltage alternating or direct current motors.

**Engineering-Contracting*, Dec. 11, 1907.

The costs submitted are probable costs between limits, but even though a maximum limit is given, the actual cost may sometimes exceed these figures, depending on local conditions.

Starting from the standpoint of the cheapest practicable construction, we have 30-ft. poles, 90 to 100 ft. spacing, and bracket supports, and with double overhead No. 000 trolley. The cost of such construction will approximate the figures given by Table IV.

TABLE IV.—COST PER MILE OF BRACKET CONSTRUCTION SINGLE TRACK
600 V. TWO NO. 000 TROLLEY WIRES, POLES SPACED 100 FT.

Fifty-three 30-ft. poles in place and framed, poles delivered on cars \$4.00 to \$6.00.....	\$ 325.00	\$ 475.00
Fifty-three brackets in place with fittings....	180.00	210.00
Ears, hangers, etc., in place.....	50.00	75.00
Two miles No. 000 trolley with splicers, at 20c-26c	1,100.00	1,400.00
Erecting same	100.00	150.00
Siding construction pro rated.....	75.00	100.00
Curve construction 1,600 ft. additional cost...	50.00	75.00
Five anchors	8.50	15.00
Two hundred ft. strand for guys.....	2.25	2.50
Two half anchorages.....	5.00	10.00
Lags, clamps, etc.....	5.00	8.00
Per cent on material for handling.....	75.00	100.00
	<hr/>	<hr/>
Add for lightning arrester.....	\$1,975.75	\$2,620.50
Add for telephone system pro rated.....	10.00	20.00
	75.00	100.00
	<hr/>	<hr/>
	\$2,060.75	\$2,740.50
If all poles are anchored add.....	180.00	265.00
If 35-ft. poles are used add (poles \$6.00 to \$8.50)	130.00	180.00
	<hr/>	<hr/>
Total	\$2,350.75	\$2,165.50

If for any reason, it is decided to use cross suspension instead of bracket construction with the same pole spacing and size of trolley, then the approximate cost will be as given by Table V.

TABLE V.—COST PER MILE OF SPAN CONSTRUCTION SINGLE TRACK
600 VOLT TWO NO. 000 TROLLEY WIRES, POLES SPACED 100 FT.

One hundred and six 30-ft. poles in place and framed, poles delivered on cars \$4.00-\$6.00..	\$ 650.00	\$ 950.00
Ears, hangers, etc., in place.....	50.00	75.00
Span wire erected.....	60.00	85.00
Two miles No. 000 trolley at 20c-26c.....	1,100.00	1,400.00
Erecting same	100.00	150.00
Siding construction, pro rated.....	75.00	100.00
Curve construction, additional cost.....	35.00	60.00
Five anchors	8.50	15.00
Two hundred ft. strand for anchor guys.....	2.25	2.50
Two half anchorages.....	5.00	10.00
Lags, clamps, etc.....	5.00	8.00
Per cent on material for handling.....	100.00	150.00
	<hr/>	<hr/>
	\$2,190.75	\$2,005.50
Lightning arresters	10.00	20.00
Telephone system, pro rated.....	75.00	100.00
If all 35-ft. poles are used (poles at \$6.00 to \$8.50)	260.00	320.00
If poles are anchored add.....	320.00	520.00
	<hr/>	<hr/>
Total	\$2,856.75	\$3,275.50

In case transmission wires are required for transmission of electric energy from the power house to substations, such transmission wires may be placed entirely on crossarms, or in the case of three-phase transmission, two of such wires may be on one two-pin arm and the third wire on a pin on the top of the pole or on a bracket on the side of the pole. Of course the pole top cannot be used if a ground wire is located at each point. The cost of construction on a three-phase transmission line will approximate the figures given by Table VI.

TABLE VI.—COST PER MILE OF BRACKET CONSTRUCTION SINGLE TRACK
600 VOLT TWO NO. 000 TROLLEY WIRES, POLES SPACED 100 FT.
WITH THREE PHASE 33,000 VOLT TRANSMISSION LINE ON
TROLLEY LINE POLES, 2-PIN CROSSARM AND
POLE TOP PIN CONSTRUCTION.

Fifty-three 35-ft. poles in place and framed, poles delivered on cars at \$6.00 to \$8.50.....	\$ 455.00	\$ 635.00
Ears, hangers, etc., in place.....	50.00	75.00
Fifty-three brackets in place with fittings.....	180.00	210.00
Two miles No. 000 trolley with splicer at 20c-26c	1,100.00	1,400.00
Erecting same	100.00	150.00
Siding construction, pro rated.....	75.00	100.00
Curve construction 1,500 ft. additional cost.....	65.00	100.00
Five anchors	8.50	15.00
Two hundred ft. strand for guys.....	2.25	2.50
Two half anchorages.....	5.00	10.00
Lags, clamps, etc.....	5.00	8.00
Fifty-three 4 x 5 in. x 4 ft. 6 in. crossarms.....	16.00	22.00
One hundred and fifty-nine 2 x 13-in. oak pins paraffined	9.00	11.00
One hundred and fifty-nine 33,000 volt porce- lain insulators	90.00	120.00
One hundred and six 20 x 1 1/4 x 1/4 in. crossarm braces galv.	5.00	6.50
One hundred and six 3/4 x 5 cgs. bolts.....	1.00	1.25
Fifty-three 1/2 x 4 lag bolts.....	.60	.75
Fifty-three 3/4 x 13 inch bolts.....	2.00	2.75
Erecting arms, pins and insulators.....	25.00	35.00
Three miles No. 2 copper wire with splicers at 20c-26c	638.40	829.92
Erecting same	125.00	170.00
Five cent on material for handling.....	140.00	190.00
Total	\$3,098.75	\$4,095.67
Add for trolley lightning protection.....	10.00	20.00
Add for transmission lightning protection.....	50.00	250.00
Add for telephone system pro rated.....	75.00	100.00
Total	\$3,233.75	\$4,465.67
If all poles are anchored add.....	160.00	265.00
Total	\$3,393.75	\$4,730.67

From the above the principal unit costs of the cheapest practicable character of line work can be ascertained, and such additions must be made as are necessary for special overhead work around car shops, and in connection with bridges, city work or other special conditions; also the cost of copper for feeders or for transmission must be added in accordance with the plan decided upon.

Tables VII to IX show the average cost between limits of different types of catenary construction.

**TABLE VII.—COST PER MILE SINGLE TRACK 9-POINT CATENARY
150-FT. POLE SPACING, 6,600 VOLT.**

Add for telephone line.....	100.00	150.00
	<hr/>	<hr/>
	\$3,714.50	\$5,406.00
If all poles are anchored.....	216.00	360.00
If all brackets are insulated.....	80.00	120.00
	<hr/>	<hr/>
Total	\$4,010.50	\$5,886.00

In deciding whether the pole line for double track shall be a double pole line or a center pole line, the character of the grading on the right-of-way will have to be taken into consideration. If, as in the Middle West, the country is practically level and no expensive cuts or fills are required, possibly the single pole construction will show a saving over the double pole; however, where there are expensive fills and cuts, the double pole construction will show a saving over the single pole, not in itself, but in the fact that the roadbed will not have to be as wide as for the single pole construction.

Estimating the Horse Power of Contractors' Engines and Boilers.*
—The size of an engine is usually expressed in terms of the diameter of the cylinder bore by the length of the piston stroke. In a 6 x 8 engine, the cylinder has a bore of 6 ins. and the piston has a stroke of 8 ins. This stroke is, of course, just twice the length of the "throw" of the crank arm. Bear in mind, therefore, that the "size of cylinder" as given in catalogues is the bore of the cylinder by the stroke of the piston, and not by the full length of the cylinder.

If a contractor's engine is designed to have a piston speed of 300 ft. per minute, and is using steam with a boiler pressure of 100 lbs., it is an easy matter to deduce a very simple rule for estimating the horsepower of the engine. The following rule is precisely correct

*Engineering-Contracting, Sept. 2, 1908.

when the product of the piston speed, by the mean effective pressure by the mechanical efficiency is equal to 1,050; and this is ordinarily the case with contractors' engines having cylinders of 8 ins. or more in diameter.

Rule: To ascertain the horsepower square the bore of the cylinder and divide by four.

Thus, if the engine is 8 x 8, we have a cylinder bore of 8. Hence, squaring 8 we have 64, and dividing by 4 we get 16, which is the horsepower. This is the actual delivered, or brake, horsepower.

For smaller engines, whose piston speeds are usually less, it is safe to divide the square of the bore by five instead of by four. A 6 x 6 engine would, therefore, have 7 horsepower.

If the engine has two cylinders (duplex), of course the horsepower is twice that of a single cylinder.

A boiler is usually estimated to give one horsepower for every 10 sq. ft. of heating surface. Hence the horsepower of a vertical tubular boiler is found thus:

Rule: Divide the total heating surface of the tubes and fire box (expressed in square feet) by ten, and the quotient is the horsepower.

The square foot heating surface of a tube is quickly calculated by multiplying the length of the tube in feet by 0.28 and then multiplying by the outside diameter of the tube in inches. Since tubes are ordinarily 2 ins., the total heating surface of the tubes is found by multiplying the number of tubes by their length in feet by 0.56; or, for all practical purposes, take half the product of the number of tubes by the length of tube in feet. To this heating surface of the tubes must be added the heating surface of the firebox, which is ascertained thus: Multiply the circumference of the firebox in feet by its height above the grate in feet and add the square foot area of the lower flue sheet.

The diameter of the firebox or furnace is usually 4 to 5 ins. less than the outside diameter of the boiler. The height of the firebox is usually 2 to 2½ ft.

The amount of coal required for a contractor's boiler is about 6 lbs. per horsepower per hour, or 66 lbs. per horsepower per day of 10 hours. Nearly one gallon of water will be required for each pound of coal. About 2¼ lbs. of dry wood are equal to 1 lb. coal, or 3 cords of wood equal 1 ton of coal.

Cost of Cutting Cord Wood.—Frequently a contractor must figure on using wood for fuel, in which case it is desirable that he know the cost of cutting and piling cord wood. The following average record relates to work done in the state of Washington under the direction of one of the editors of this journal. The work involved the felling of the trees, which were fir, sawing them into cordwood lengths (4 ft.), splitting and piling. Axmen averaged 3 cords per 10-hour day, but an extra good woodman will readily average 3 cords per day. With wages at \$2.50, a cord of wood cost \$1.25 ready for hauling.

**Engineering-Contracting*, Oct. 7, 1902.

A cord measures 128 cu. ft., of which about 65% is solid wood, the remaining 35% being the voids or spaces between the sticks. Washington fir when green weighs about 3.5 lbs. per ft. B. M., and about 2.2 lbs. when dry. Hence a cord of green fir weighs about 3,800 lbs., or 1.6 tons, which is a good wagon load on most roads. About 10 cords is the ordinary carload.

The daily papers of Sept. 27 contained an Associated Press dispatch from which we have abstracted the following record of wood chopping on a wager. A Vermont woodsman undertook to cut down, chop up, split and pile 5 cords of basswood between sunrise and sunset. He did it, with nearly an hour and a half to spare, for he had completed his work in 10 hours, and had half a cord of unpiled wood left over. The trees ranged in length from 60 to 70 ft. and were 9 to 13 ins. diameter at the butt. At the end of 4 hrs. and 40 mins. he had felled 18 trees and had chopped and split $3\frac{1}{2}$ cords. It took him about 2 hrs. and 40 mins. to pile the 5 cords.

This record is said to be the best ever made. It is interesting to note that this man's output was about double what is regarded as a good day's work, and, in this respect, the record bears out the generalization that a man can perform on a wager about double the physical work that he is accustomed to do day in and day out.

ADVERTISEMENTS

The Cube's Fundamental Principle

Is Mixing by Incorporation Under Pressure

No other form of mixing drum gives this principle in its perfection. Some will fold the batch like the cube, some will give it alternate changes of shape, but none will fold it to the right 4 times, to the left 4 times and forward 4 times, changing its shape by pressure 8 times every revolution.

No other form of mixer subjects the entire batch to each motion. All mixers with inside disintegrators act on the batch piecemeal. The fundamental principle of their operation is mixing "by tearing apart and throwing together," which is absolutely different from the kneading action of the cube and vastly inferior as a mixing action.

The mixing action of the cube is that of the expert cement tester in mixing cement paste for test briquettes. Cement testers have tried "shakers" and "stirrers" innumerable but none gave the same perfect result as kneading the paste. **Kneading** is the fundamental principle of mixing a pasty material. It is the principle of the **AUSTIN CUBE MIXER**.

ROCK DRILLS

AND ROCK EXCAVATING MACHINERY

FOR EVERY PURPOSE

Every important piece of engineering-contracting since 1871 has been carried to a successful issue by the aid of Ingersoll-Rand contractors' machinery.

In the list of products opposite, every advanced type of cost-reducing contract equipment will be found, and each line is backed by the guarantees of the oldest, largest and most responsible builders of air power machinery in the world.

Profit-earning contractors' equipment means "Ingersoll-Rand equipment." Pamphlets on any line will be sent on request.
